Since left ventricular contractile function is normal in pure MS, digitalis glycosides have no beneficial hemodynamic effect and are useful only as agents for ventricular rate control if atrial fibrillation supervenes, though beta blockers are preferred for this purpose. There is insufficient evidence to support the routine use of anticoagulants to reduce the risk of thromboembolic events in patients with MS in the absence of atrial fibrillation, a history of thromboembolism, or extreme left atrial enlargement.

As reviewed in the Answer to Question 464, endocarditis prophylaxis before dental procedures is not recommended for native valve abnormalities such as MS.

ANSWER TO QUESTION 524

D (Braunwald, pp. 1676–1677)

Most cases of infectious acute pericarditis are caused by a virus. The most commonly implicated viruses are the enteroviruses and adenovirus. In contrast, the incidence of nontuberculous bacterial pericarditis is low, approximately 5% of cases, and it develops most often as a complication of pneumonia, mediastinitis, or infective endocarditis. The most frequently involved bacterial organisms are streptococcal and staphylococcal species. The overall survival in bacterial pericarditis is poor, averaging 30%.

Tuberculosis was once the leading cause of constrictive pericarditis worldwide. However, with effective screening and treatment programs, the incidence of this condition is now rare in developed nations, and it is encountered mostly in immunocompromised hosts and in developing societies.

Pericarditis associated with fungal disease is most often caused by *Histoplasma*. It occurs in otherwise healthy young individuals and is thought to be a noninfectious inflammatory effusion secondary to fungal infection in nearby mediastinal lymph nodes. This process should be considered in patients with suspected pericarditis who live where the fungus is endemic—the Ohio and Mississippi rivers' valleys. It is generally a self-limited disease, and treatment typically consists of nonsteroidal anti-inflammatory agents without antifungal therapy. The latter is necessary only when there is evidence of disseminated histoplasmosis.

ANSWER TO QUESTION 525

D (Braunwald, pp. 1621–1622)

Chagas disease is caused by the protozoan *Trypanosoma cruzi*. It is prevalent in Central and South America, where 8 to 10 million people are infected. The disease is characterized by three phases: acute, latent, and chronic. During the acute phase, the disease is transmitted to humans by the bite of a reduviid bug, commonly called the kissing bug. After inoculation, protozoa multiply and migrate widely through the body. Clinical manifestations during the acute phase may include fever, muscle pains, hepatosplenomegaly, myocarditis, and meningoencephalitis. The disease then enters an asymptomatic latent phase for many years. Typically, chronic cardiac manifestations become evident 5 to 15 years after the initial infection. Interestingly, only 30% of infected individuals develop symptoms of chronic Chagas disease, and many individuals with high parasite burdens do not. There is poor correlation between the level of parasitemia and the severity of disease later.

The major cardiovascular findings of the chronic phase of Chagas disease include myocardial fibrosis, conduction system abnormalities, ventricular dilation (dilated cardiomyopathy), and apical aneurysm formation. Associated clinical manifestations include progressive heart failure (predominantly right-sided), arrhythmias, conduction disturbances, and possible thromboembolism. There is usually severe cardiomegaly, with the most common electrocardiographic abnormalities being *right* bundle branch block and left anterior fascicular block; atrioventricular block occurs less frequently. Ventricular arrhythmias are common.

The diagnosis of Chagas disease is confirmed using a complement-fixation test (Machado-Guerreiro test). Antitrypanosomal therapy should be administered to patients with acute disease, those with positive serologies without symptoms of chronic disease, and those with early cardiac involvement. Such therapy is not effective in reversing pathologic changes and complications in those with advanced chronic Chagas cardiac disease; standard heart failure and antiarrhythmic treatments should be undertaken instead.

ANSWER TO QUESTION 526

C (Braunwald, p. 1537)

The echocardiogram demonstrates prominent echogenicity along both surfaces of the interatrial septum (*arrow* in Fig. 4.39), consistent with normal deployment of a transcatheter atrial septal defect (ASD) closure device. Indications for this method are the same as for surgical closure of an ASD, but strict structural criteria must be met. Successful closure can be accomplished in the majority of patients, and complications, such as device embolization or atrial perforation, are rare.

Atrial myxomas are the most common primary heart tumor. When attached to the interatrial septum, echocardiography most commonly demonstrates a mobile mass attached to the limbus of the fossa ovalis by a stalk. Lipomatous hypertrophy of the interatrial septum occurs most

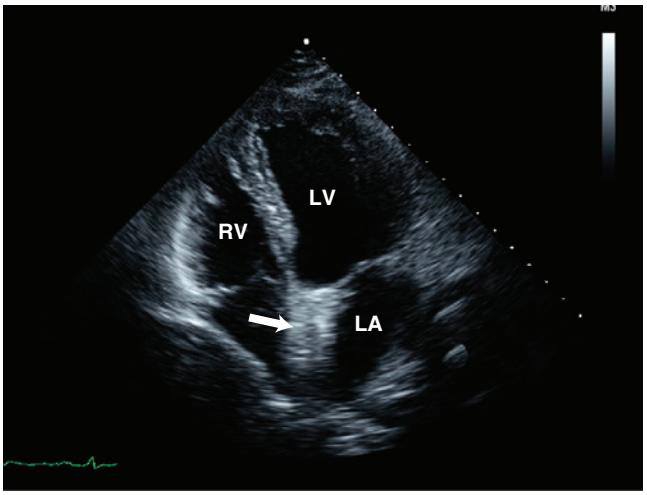

FIG. 4.39

often in obese, elderly female patients. It represents a prominent fatty deposition at the interatrial septum that spares the fossa ovalis, creating a thick "dumbbell" appearance on echocardiography. This condition is associated with a high incidence of atrial arrhythmias. In cardiac amyloidosis, infiltration causes increased thickness of all cardiac chamber walls, not just the interatrial septum.

ANSWER TO QUESTION 527

D (Braunwald, pp. 1415–1420; Fig. 69.1; see also Answer to Question 467)

The parasternal long-axis view displays typical rheumatic deformity of the mitral valve with diastolic doming of the leaflets, with a "hockey-stick" appearance of the anterior leaflet (*arrow* in Fig. 4.40). There is accompanying left atrial enlargement. The transmitral spectral Doppler in part *B* in Fig. 4.29 shows an increased early diastolic velocity with a slowed diastolic descent, indicative of a diastolic pressure gradient across the valve due to mitral stenosis (MS).

Atrial fibrillation (AF) is common in patients with MS, and the prevalence increases with age. It tends to be poorly tolerated because of the lack of effective atrial contribution to left ventricular filling and the shortened diastolic filling time in patients with rapid ventricular rates. AF also predisposes to atrial thrombus formation and embolization. The risk of systemic embolism in MS correlates directly with patient age and left atrial size and inversely with cardiac output.

Infective endocarditis in MS tends to be more common in patients with milder forms of the disease, occurring less frequently on very thickened and calcified mitral valves.

Only about 15% of patients with isolated MS experience anginal-type chest discomfort. This symptom may arise from right ventricular hypertension, concomitant atherosclerosis, or coronary obstruction due to embolization of left atrial thrombus.

ANSWER TO QUESTION 528

A (Braunwald, pp. 1542–1543)

These findings are consistent with patent ductus arteriosus (PDA). In the majority of preterm infants weighing <1500 g, a PDA persists for a prolonged period, and in approximately one-third of those infants, a large shunt leads to significant cardiopulmonary deterioration. Noninvasive evaluation may reveal evidence of significant shunting before the appearance of physical findings of ductal patency. Physical examination may reveal bounding peripheral pulses, an infraclavicular and interscapular systolic murmur (sometimes heard as a continuous murmur), a hyperactive precordium, hepatomegaly, and recurrent episodes of apnea and bradycardia. An increase in the cardiothoracic ratio is seen on sequential chest radiographs and may be accompanied by increased pulmonary arterial markings, perihilar edema, and ultimately generalized pulmonary edema. Echocardiography may demonstrate increased left ventricular end-diastolic and left atrial dimensions, and color Doppler confirms the presence of left-to-right shunting.

Management of the premature infant with a PDA depends on the clinical presentation of the disorder. In an asymptomatic infant, intervention is usually unnecessary, because the PDA will almost always undergo spontaneous closure and will not require surgical ligation and division. Infants with respiratory distress syndrome and signs of a significant ductal shunt usually are unresponsive to medical measures to control congestive heart failure and require closure of the PDA for survival. This is usually accomplished pharmacologically with indomethacin to inhibit prostaglandin synthesis and achieve constriction and closure. Approximately 10% of infants are unresponsive to indomethacin and require ligation.

ANSWER TO QUESTION 529

A (Braunwald, pp. 1603–1609)

The echocardiogram demonstrates hypertrophic cardiomyopathy (HCM) with asymmetric septal hypertrophy. The most common physiologic abnormality in HCM is not systolic, but rather diastolic dysfunction. HCM is characterized by abnormal stiffness of the left ventricle, which results in impaired diastolic filling. The abnormal diastolic relaxation increases the left ventricular (LV) end-diastolic pressure with subsequent elevations of left atrial, pulmonary venous, and pulmonary capillary pressures.

Although the generation of a pressure gradient due to associated subaortic obstruction would imply that LV ejection

is slowed or impeded during systole, there is actually *rapid* ventricular emptying and a normal, or even augmented, ejection fraction in such patients. Hemodynamic studies have confirmed that the majority of LV output is unusually rapid in patients with HCM and is completed earlier in systole than normal, regardless of whether an outflow gradient is present. Thus, the common symptom of dyspnea in this condition is largely due to impaired diastolic relaxation rather than compromised systolic ejection. Although there is a strong temporal and quantitative relationship between mitral valve systolic anterior motion and the development of subaortic obstruction, symptoms do not necessarily correlate with the magnitude of the generated gradient. Furthermore, there can be significant variations on a daily basis in both the extent of the obstruction (and associated murmur) and symptomatology.

Exertional syncope and angina occur in some patients with HCM, and these symptoms are likely related, at least in part, to systolic obstruction.

The echolucent space posterior to the left ventricle in the echocardiogram represents a tiny pericardial effusion.

ANSWER TO QUESTION 530

D (Braunwald, pp. 1409–1410)

Acute aortic regurgitation (AR) is most often caused by infective endocarditis, aortic dissection, or trauma. Many of the physical findings typical of chronic AR are not present in patients with acute AR. In acute AR, the left ventricle has not yet dilated and is relatively noncompliant, such that its early diastolic pressure rises rapidly. If the resulting left ventricular (LV) diastolic pressure exceeds the left atrial pressure, the mitral valve may close *prematurely* and can produce diastolic mitral regurgitation. Because the elevated LV diastolic pressure blunts runoff of blood from the aorta into the left ventricle, the aortic diastolic pressure does not decline as substantially as in chronic AR. Therefore, the pulse pressure does not widen significantly, and physical findings typical of an increased pulse pressure, such as Corrigan pulse (abrupt upstroke, then quick collapse of the arterial pulse), are absent. Similarly, the duration of the diastolic murmur is shorter than in chronic AR.

ANSWER TO QUESTION 531

A (Braunwald, pp. 1544–1547, 1574–1575; see also Answer to Question 481)

Tetralogy of Fallot is the most common cyanotic congenital cardiac defect that presents after the newborn period. Most experts advocate surgical repair in the first 6 months of life to avoid chronic cyanosis and its complications. Although initial operative outcomes are excellent, provided that the ventricular septal defect is adequately closed and right ventricular outflow tract obstruction is relieved, many patients develop progressive pulmonary regurgitation, especially when a transannular patch is used to enlarge the right ventricular outflow tract. The optimal timing to correct this complication with pulmonary valve replacement (PVR) remains uncertain, but it is appreciated that PVR should be performed when there is severe pulmonary regurgitation with substantial right ventricular dilation or dysfunction, even in the absence of subjective dyspnea. In fact, adults with congenital heart disease tend to underestimate their exercise intolerance, underscoring the importance of objective measures of exercise capacity, such as cardiopulmonary exercise testing.

Patients with repaired tetralogy of Fallot are at increased risk of sudden death (SD). Although criteria for an implantable cardioverter-defibrillator for primary prevention remain controversial, a QRS width >180 ms and left ventricular dysfunction have been identified as risk factors for SD. Atrial arrhythmias are also common in patients with repaired tetralogy of Fallot; risk factors include left atrial dilation and tricuspid regurgitation.

The American Heart Association guideline for the prevention of endocarditis recommends predental antibiotic prophylaxis for patients with repaired congenital heart disease with residual defects at the site of, or adjacent to, prosthetic material (e.g., Dacron patch).

ANSWER TO QUESTION 532

B (Braunwald, pp. 1713–1715)

The development of pulmonary hypertension in patients with chronic obstructive lung disease (COPD) arises from several factors including pulmonary vasoconstriction induced by alveolar hypoxemia, acidemia, the mechanical effects of high lung volumes on the pulmonary vessels, and small-vessel loss in regions of emphysema.[1] Right ventricular (RV) hypertrophy and dilatation may develop over time (Fig. 4.41).

The only effective treatment for patients with COPD and pulmonary hypertension is supplemental oxygen, with several studies showing an improvement in morbidity and mortality.[2] In a series of trials in the 1980s, continuous oxygen supplementation was more effective than nocturnal therapy alone. Thus, long-term oxygen therapy is recommended if the resting PaO_2 is <60 mm Hg.

Although digoxin may improve the RV ejection fraction in some patients with RV dilation and dysfunction, it can also contribute to adverse pulmonary vasoconstriction and has not been shown to have a beneficial effect on survival.

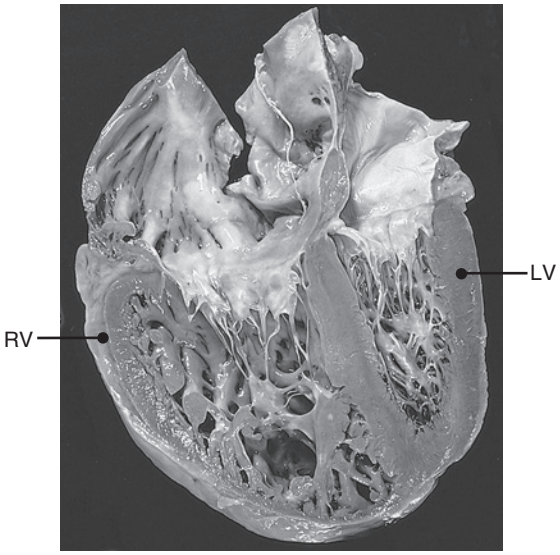

FIG. 4.41 *From Kumar V, Abbas AK, Fausto N, eds.* Robbins and Cotran Pathologic Basis of Disease. *7th ed. Philadelphia: Elsevier; 2005:588.*

Furthermore, digitalis toxicity may be precipitated by the hypoxemia and acidemia often associated with COPD. Theophylline, beta-agonists, hydralazine, and other pulmonary vasodilators (e.g., phosphodiesterase inhibitors, endothelin receptor antagonists such as bosentan) have not been shown to improve survival of patients with pulmonary hypertension due to COPD.[3–5]

ANSWER TO QUESTION 533

B (Braunwald, pp. 1559–1561)

Coarctation of the aorta (Fig. 4.42) occurs two to five times more commonly in males.[1] Most infants and children with coarctation are asymptomatic. In contrast, neonates with severe coarctation often develop overt heart failure due to the sudden rise in left ventricular (LV) afterload when the ductus arteriosus closes at birth. Coarctations discovered in the adult are frequently associated with additional abnormalities, including bicuspid aortic valve (50% to 85%) and intracranial aneurysms.

Pathophysiologically, significant coarctation places a pressure load on the left ventricle, which leads to LV hypertrophy and ultimately heart failure. On physical examination, findings include a differential systolic blood pressure (brachial artery pressure greater than popliteal artery pressure by >10 mm Hg) and radial-femoral pulse delay. The mean survival time of patients with uncorrected coarctation is 35 years. Heart failure is the most common cause of death in adults, followed by bacterial endocarditis, intracranial hemorrhage, and aortic dissection. Surgical repair is associated with low mortality. Outcomes are most influenced by the presence of other congenital anomalies or more complex variants of aortic coarctation involving the aortic arch, rather than the type of surgery performed.

Recoarctation and true aneurysm formation at the site of repair can occur.[2] The reported incidence of these complications varies widely in the surgical literature, ranging from 6% to 60%. Prior hypertension resolves in up to 50% of patients but it may recur later in life.[2,3]

ANSWER TO QUESTION 534

B (Braunwald, p. 1869)

The apical four-chamber views demonstrate a large mass attached to the interatrial septum, which in diastole prolapses across the orifice of the mitral valve and is most consistent with a left atrial myxoma. Echocardiography is helpful in differentiating between left atrial thrombus and myxoma. Thrombus usually produces a layered appearance and tends to localize to the more posterior segments of the atrium. In contrast, left atrial myxoma is often mottled in appearance and typically attaches along the limbus of the fossa ovalis of the interatrial septum. In some atrial myxomas, including the one demonstrated here, echolucent areas are seen within the tumor mass that correspond pathologically to regions of hemorrhage.

Eighty-three percent of cardiac myxomas appear in the left atrium and 12.7% in the right atrium; the remainder are biatrial or located in one of the ventricles. Signs and symptoms of left atrial myxoma may be similar to those of mitral valve disease owing to interference of the mass with normal mitral valvular function. Physical examination may demonstrate pulmonary congestion and an intensified S_1. It is believed that the loud S_1 occurs when there is late onset of mitral valve closure as a consequence of tumor prolapse through the valvular orifice. An early diastolic sound (tumor "plop") may be present, although this is often positional and may be confused with an S_3. Cardiac myxomas may also produce a variety of constitutional symptoms and extracardiac findings, including fever, weight loss, and arthralgias. These symptoms have been attributed to the tumor's production of interleukin-6. Several abnormal laboratory findings may be present, including an elevated erythrocyte sedimentation rate, polycythemia, leukocytosis, and anemia.

Approximately 10% of cardiac myxomas are familial. In such cases, patients typically present at a younger age

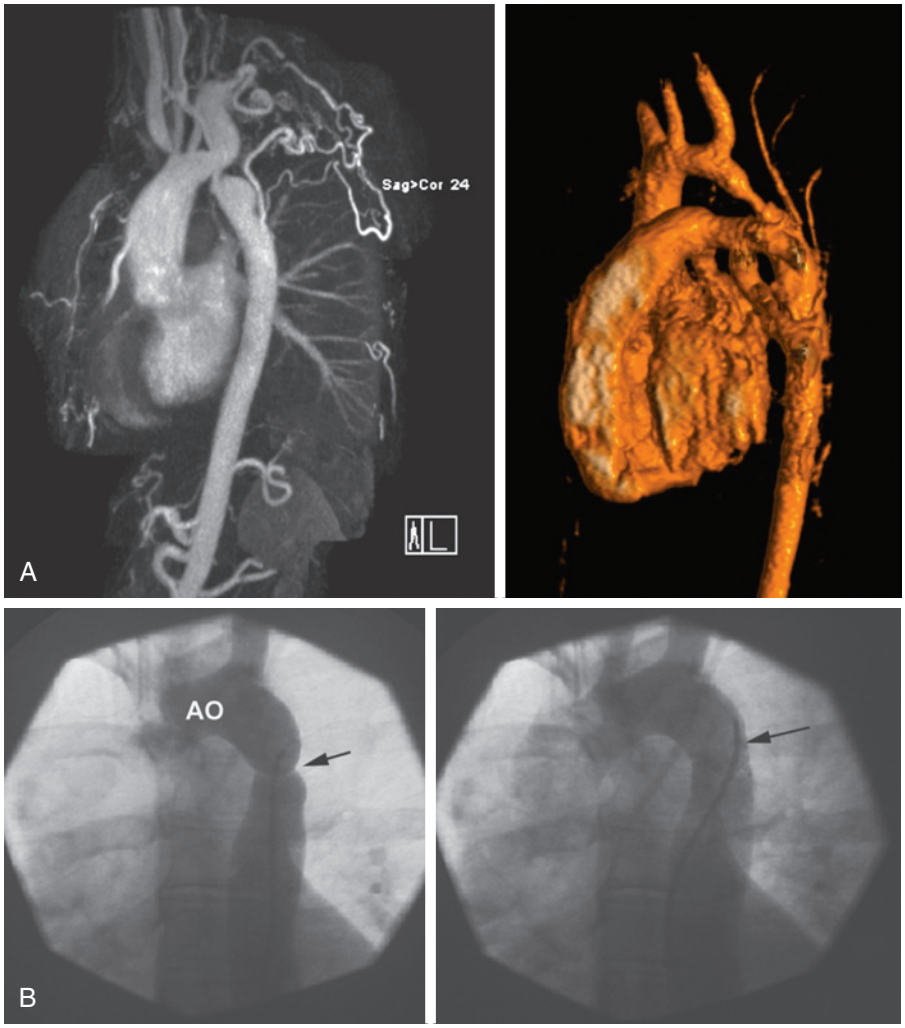

FIG. 4.42 *(A) Montage of coarctation of the aorta. The left image is a specimen that shows the site of the posterior shelf. The right image is from magnetic resonance imaging and shows the posterior shelf and some associated transverse arch hypoplasia. (B) Angiogram of coarctation of the aorta before and after stenting* (arrows). AO, *Aorta.*

and are more likely to have multiple additional myxomas in noncardiac locations. *Carney complex* is inherited as an autosomal dominant syndrome consisting of cardiac myxomas, along with dermatologic (hyperpigmented skin lesions) and endocrine abnormalities (adrenal, pituitary, testicular).

The treatment of symptomatic cardiac myxoma is prompt surgical resection of the tumor. Recurrences appear in approximately 3% of patients, with a higher incidence in those with familial myxomas.

ANSWER TO QUESTION 535

D (Braunwald, pp. 1686–1689; Fig. 84.11)

The diagnostic approach for possible pulmonary embolism (PE) involves careful clinical assessment in conjunction with judicious diagnostic testing (Fig. 4.43). The most common symptoms of PE are dyspnea and pleuritic chest pain. Physical examination may be unremarkable, or findings may include tachycardia, tachypnea, and increased intensity of the pulmonic component of S_2.

Arterial blood gas determinations are generally not helpful in the diagnosis of PE. In the Prospective Investigation of Pulmonary Embolism Diagnosis (PIOPED) study, the PaO_2 did not differentiate between individuals with and without PE. Thus, normal values of the alveolar-arterial oxygen gradient do not exclude PE.

When PE is highly suspected, chest computed tomographic (CT) angiography is the superior imaging test.[1,2] This technique has the capability to visualize even subsegmental pulmonary emboli. When the clinical probability of PE is not high, a normal plasma D-dimer assay usually suffices to rule out this condition.[3,4] The D-dimer assay is highly sensitive for the presence of PE, but has low specificity because elevations also occur in sepsis, recent surgery or trauma, malignancies, and other systemic illnesses. A normal D-dimer assay therefore has excellent negative predictive value.

In patients with large PE, electrocardiographic signs of right-sided heart strain may be present (including ST-segment and T wave abnormalities in the right precordial leads (V1–V4), right-axis deviation, new right bundle branch block,

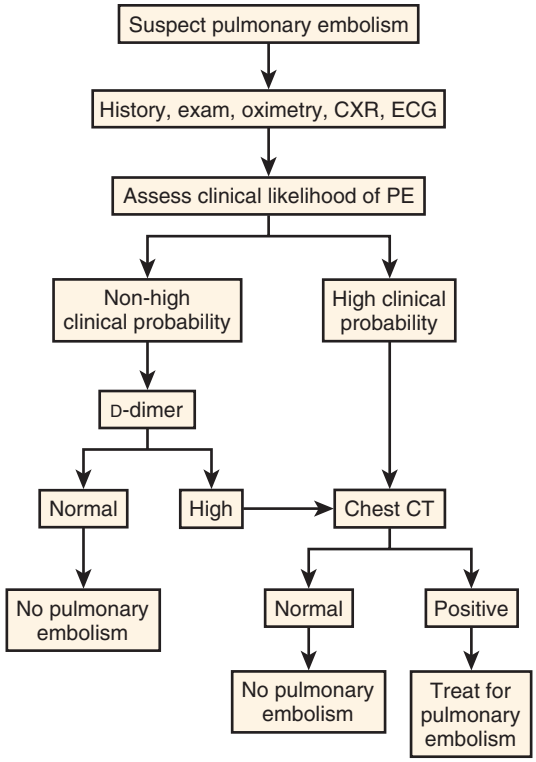

FIG. 4.43

and an $S_1Q_3T_3$ pattern), but such findings are generally absent when small PEs are present. The most common electrocardiographic abnormality in PE is simply sinus tachycardia, and a normal tracing does not exclude PE.

Ventilation-perfusion lung scanning results are often ambiguous. Although PE is very unlikely to be present with a completely normal scan, and very likely when the test is "high probability," scans frequently fall between these two extremes ("intermediate probability") and do not provide definitive results. This test is now useful for diagnosis of acute PE only in occasional circumstances (e.g., renal insufficiency, a history of anaphylaxis to IV contrast agents precluding a CT angiogram, or pregnancy).

ANSWER TO QUESTION 536

D (Braunwald, pp. 1866–1973)

Primary tumors of the heart are rare (autopsy incidence 0.001% to 0.03%), with benign tumors representing >80%. The majority of benign cardiac tumors are myxomas, followed in frequency by lipomas, papillary fibroelastomas, rhabdomyomas, and fibromas. Among the malignant tumors, the most common are sarcomas, and of these, angiosarcoma and rhabdomyosarcoma are the most frequent forms.[1]

Although it can be difficult to differentiate benign from malignant tumors clinically, certain findings may be helpful. The presence of distant metastases, local mediastinal invasion, evidence of rapid growth in tumor size, hemorrhagic pericardial effusion, precordial pain, location of the tumor on the *right* as opposed to the left side of the heart, and extension into the pulmonary veins are all suggestive of a malignant rather than a benign tumor. Furthermore, infiltration of the myocardium is more indicative of a malignant process.[2] Benign tumors are more likely to occur on the left side of the interatrial septum and to grow slowly.

Cardiac symptoms caused by tumors are primarily determined by mechanical interferences. Myxomas that are located on the left side may produce mitral valve symptoms, whereas right-sided malignant tumors may produce signs of right-sided failure.[3]

ANSWER TO QUESTION 537

C (Braunwald, pp. 1702–1704)

Echocardiography is the most useful noninvasive test to evaluate for cardiac tamponade.[1] Findings most suggestive of tamponade physiology include (1) a large pericardial effusion, (2) right atrial (RA) and right ventricular (RV) diastolic compression, (3) an exaggerated inspiratory *increase* in transtricuspid flow velocities with concurrent *decrease* in transmitral flow velocities, and (4) inferior vena caval dilatation with absence of normal inspiratory collapse.

RV diastolic collapse is the most predictive sign of tamponade. It is more specific than RA compression and more sensitive and specific than pulsus paradoxus in detecting increased pericardial pressure. However, diastolic RV collapse may not be evident in patients with elevated intrapericardial pressure who also have pulmonary hypertension, because RV pressures are higher than normal in that case.

A small pericardial effusion makes tamponade less likely, but does not exclude the diagnosis, especially if the pericardial fluid has accumulated rapidly. In addition, small pericardial effusions can be associated with "low-pressure" tamponade in patients with intravascular volume depletion. Small loculated effusions (e.g., after cardiac surgery) can also result in tamponade physiology because of localized chamber compression.

ANSWER TO QUESTION 538

D (Braunwald, pp. 1672–1674)

The lateral chest radiograph shows calcification of the pericardium, suggestive of constrictive pericarditis. In this patient's case, prior radiation therapy is the likely cause of constriction.

The clinical presentation of patients with chronic constrictive pericarditis (CP) is predominantly that of right-sided heart failure. In early stages, signs include jugular venous distention (with a rapid *y* descent) and Kussmaul sign (inspiratory augmentation of the jugular venous pressure, instead of the normal decline), peripheral edema, and vague abdominal discomfort due to passive hepatic congestion. As the disease progresses, ascites, jaundice, and anasarca may ensue.

The most notable auscultatory finding observed in some patients with advanced CP is the pericardial knock, an early diastolic sound heard best at the left sternal border or apex that corresponds to the sudden cessation of ventricular filling imposed by the rigid, constricting pericardium. The pericardial knock occurs earlier and is of higher frequency than an S_3 gallop sound and may be confused with the opening snap of mitral stenosis (MS), but is not followed by the diastolic rumbling murmur of MS.

Heart catheterization in patients with CP is notable for elevation and equalization of the intracardiac diastolic pressures and a diastolic "dip-and-plateau" configuration of the ventricular pressure tracings. Intravascular volume depletion can mask these typical hemodynamic findings, but they can be uncovered with an intravenous fluid challenge. One important way to distinguish CP from restrictive cardiomyopathy (CMP) during catheterization is to observe the variation in simultaneously recorded right and left ventricular systolic pressures. In contrast to normal individuals or those with restrictive CMP, there is usually a striking *discordance* between these pressures during respiration in CP: with inspiration, the left ventricular systolic pressure falls while that of the right ventricle increases. This finding reflects the exaggerated ventricular interdependence that results from pericardial constraint.

ANSWER TO QUESTION 539

D (Braunwald, pp. 1389–1390)

The three primary causes of valvular aortic stenosis (AS) are (1) a congenitally bicuspid valve that becomes calcified, (2) calcification of a structurally normal trileaflet valve, and (3) rheumatic disease (Fig. 4.44). Calcification of a congenitally bicuspid or of a normal trileaflet valve is the most common etiology of AS in adults.

Although calcific aortic valve disease was once considered to result from years of mechanical stress on the valve, it actually appears to represent proliferative and inflammatory changes, with lipid accumulation and infiltration of macrophages and T lymphocytes, in a manner similar to vascular calcification. As in atherosclerosis, cigarette smoking, hyperlipidemia, and diabetes are risk factors for the development of this valvular process.

Rheumatic valvular disease has declined in frequency in industrialized countries, but remains an important condition in developing nations. Rheumatic AS results from postinflammatory fusion and adhesion of the valve commissures and rarely develops in the absence of rheumatic mitral involvement.

ANSWER TO QUESTION 540

C (Braunwald, pp. 1407–1409; Fig. 68.19)

Appropriate timing for surgical intervention in chronic aortic regurgitation (AR) depends on the patient's symptoms and state of left ventricular (LV) contractile function. Regardless of the severity of AR, patients who are symptomatic and have reduced LV systolic function should be referred for surgery, unless an absolute contraindication exists.[1] Asymptomatic patients with advanced AR who have normal LV systolic function without prominent ventricular dilatation (i.e., an end-systolic diameter <50 mm) have an excellent prognosis and typically can be observed clinically and by echocardiography to assess for changes in LV size and function.

In patients who do undergo aortic valve surgery, the end-systolic diameter is valuable in predicting the postoperative outcome. An end-systolic diameter <40 mm predicts a low likelihood of postoperative instability or heart failure. However, an end-systolic diameter >55 mm, or a preoperative ejection fraction <50%, increases the risk of postoperative death from LV dysfunction.[1]

Several vasodilators, including angiotensin-converting enzyme inhibitors, have been shown to provide beneficial hemodynamic effects in chronic AR. However, a randomized trial comparing nifedipine, enalapril, and placebo in patients with chronic AR did not demonstrate a benefit of either vasodilator regimen in reducing symptoms or LV dysfunction warranting valve replacement.[2]

Fig. 4.45 summarizes the current American Heart Association/American College of Cardiology Foundation management strategy for patients with chronic severe AR.[1]

Roberts, Baylor University Medical Center, Dallas, TX.*

immunodeficiency virus (HIV)-infected individuals taking antiretroviral therapy (ART).[1] Although most HIV-associated CV disease is related to atherosclerosis, HIV and ART can affect the myocardium and pericardium as well.[2] In the pre-ART era, HIV-associated cardiomyopathy was commonly seen in patients with advanced HIV disease and was associated with a poor prognosis. While the incidence of dilated cardiomyopathy has decreased dramatically in the current era, HIV patients who are not adherent to ART remain at risk.[3,4] In addition, more subtle LV dysfunction (both systolic and diastolic) may be detected on echocardiography in asymptomatic HIV patients taking ART.[5] Putative mechanisms for LV dysfunction include direct viral infection of cardiomyocytes, immune-mediated myocarditis, nutritional deficiencies, and direct toxicities of antiretroviral therapies.

Pericardial effusion was also common among HIV patients in the pre-ART era, but the incidence has declined significantly with current therapies.[6] Typically, such effusions are small and a large number resolve spontaneously. Most are of "idiopathic" origin, but can also be related to opportunistic infections, drug toxicities, uremia, or malignancy. The presence of a pericardial effusion increases the mortality risk in HIV-infected patients.

In the contemporary era, most cardiovascular complications in HIV-infected patients are the result of accelerated atherosclerotic disease. Potential contributory mechanisms may include direct HIV vasculopathy with endothelial dysfunction, chronic inflammation, or co-infection with other viruses. Moreover, ART drugs, especially earlier generation protease inhibitors, can contribute to dyslipidemia and insulin resistance, predisposing to increased risk of myocardial infarction.[7]

ANSWER TO QUESTION 542

A (Braunwald, pp. 1527, 1560)

Turner syndrome, also termed *gonadal dysgenesis*, occurs in 1 of every 2500 females. Clinical features include primary amenorrhea, short stature, and immature genital and breast development. The condition arises from defects of the X chromosome, including the 45,XO karyotype in about 50% of cases. Cardiovascular abnormalities are common, occurring in 20% to 50% of patients.[1] The most frequent manifestation is coarctation of the aorta, found in 50% to 70% of patients with Turner syndrome who have cardiovascular defects. Coarctation can occur alone or in combination with other aortic abnormalities, including bicuspid aortic valve and a dilated aortic root.

Patients with Turner syndrome are also at increased risk for aortic dissection independent of other aortic abnormalities. Histopathologic studies have shown abnormalities of the elastic media similar to those in patients with diseases of collagen formation. Partial anomalous pulmonary venous drainage is also found frequently in patients with this condition.

ANSWER TO QUESTION 543

B (Braunwald, pp. 1890–1893)

Duchenne muscular dystrophy (DMD) is an X-linked recessive disorder that arises from mutations in the gene that encodes dystrophin.[1] Most patients with DMD develop dilated cardiomyopathy, and specific mutations in the dystrophin gene predict ventricular dysfunction.[2] Preclinical cardiac involvement is present in 25% of DMD patients by age 6. Up to 90% of patients with DMD who are 18 years of age or older will have developed echocardiographic evidence of dilated cardiomyopathy. There is a predilection for involvement of the inferobasal and lateral left ventricle, which likely accounts for the classic electrocardiographic abnormalities: tall R waves with increased R/S amplitude in V_1 and deep narrow Q waves in the left precordial leads (Fig. 4.46). There does not appear to be an association between the presence of dilated cardiomyopathy and electrocardiographic abnormalities.[3]

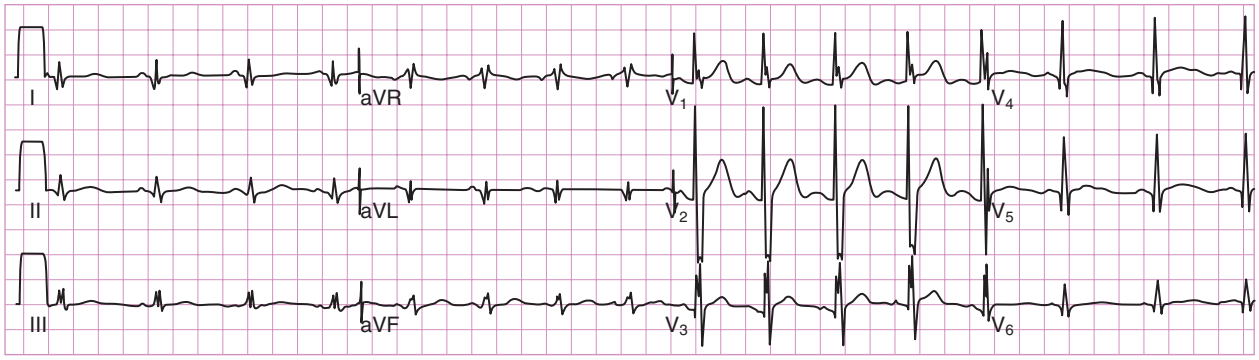

FIG. 4.46 *Dilated cardiomyopathy in a 19-year-old man with Duchenne muscular dystrophy. ECG shows a QRS complex that is typical of a Duchenne muscular dystrophy, with tall R waves in V1 and deep narrow Q waves in leads I and aVL.*

Persistent or labile sinus tachycardia is the most common arrhythmia in DMD. In advanced DMD cardiomyopathy, both atrial arrhythmias (including atrial fibrillation and atrial flutter) and ventricular arrhythmias occur, similar to other cardiomyopathies.[4]

ANSWER TO QUESTION 544

C (Braunwald, pp. 1641–1643)

The anthracycline antineoplastic agents (doxorubicin, daunorubicin, and idarubicin) are widely recognized for their potential cardiac toxicity. Rarely, a single high dose of an anthracycline causes an acute cardiotoxic reaction manifested by atrial and ventricular arrhythmias and conduction disturbances. The more common complication is chronic cardiomyopathy after long-term exposure.[1] The major risk factor for this complication is the cumulative dose. Retrospective analyses have indicated that the incidence of heart failure is 1.7% at a cumulative dose of 300 mg/m^2, 4.7% at 400 mg/m^2, 15.7% at 500 mg/m^2, and 48% at 650 mg/m^2.[2] Thus, oncologists typically limit the total dose to no more than 400 to 450 mg/m^2. Age at the time of exposure is another important risk factor, because the very young and the very old are particularly susceptible.[1]

Additional risk factors for anthracycline cardiotoxicity include prior mediastinal radiation, the concurrent administration of other cardiotoxic agents (e.g., cyclophosphamide or trastuzumab), and a history of cardiac disease. For example, cardiotoxicity is more likely to arise when the baseline left ventricular ejection fraction is <50%.[3]

In randomized trials, the iron chelator dexrazoxane has demonstrated a protective effect against anthracycline cardiotoxicity. Because there has been concern that dexrazoxane may reduce anthracycline anti-neoplastic efficacy, its use is generally limited to patients who have received >300 mg/m^2 of doxorubicin or its equivalent.

ANSWER TO QUESTION 545

C (Braunwald, p. 1645)

Vascular endothelial growth factor (VEGF) antagonists interfere with the vascular supply of tumors. The monoclonal antibody bevacizumab targets VEGF-A, and when combined with chemotherapy, improves survival in patients with metastatic colorectal cancer and metastatic nonsquamous non-small cell lung cancer. Several adverse reactions may occur with this agent. Hypertension (not hypotension) is a common side effect and can be severe in 8% to 20% of patients. Bevacizumab is also associated with heart failure, and although the risk of precipitating left ventricular dysfunction is low, it is more likely to develop in patients who have also received anthracyclines or irradiation. There is an approximately twofold increase in arterial (but not venous) thromboembolic events with bevacizumab.[1,2]

Hemorrhagic pericardial effusion is not a common side effect of bevacizumab therapy.

ANSWER TO QUESTION 546

B (Braunwald, pp. 1527, 1538–1541)

Congenital heart lesions are the most common cause of morbidity and mortality in individuals with Down syndrome. The most frequent abnormalities are endocardial cushion defects, including partial or complete atrioventricular septal defects. The typical presentation includes a history of poor weight gain and frequent respiratory infections in the first year of life. Cardiac auscultation findings depend on the degree of atrial and ventricular septal communications and whether there is atrioventricular valve involvement. In patients with the more common partial endocardial cushion defect, the examination findings are similar to those of an ostium primum atrial septal defect. There is a prominent midsystolic flow murmur (because of increased flow across the pulmonic valve) followed by wide, fixed splitting of S_2. A middiastolic murmur is also common owing to increased flow through the tricuspid valve. When a cleft mitral valve is part of the partial endocardial cushion defect, a holosystolic murmur at the apex is present that frequently radiates toward the sternum, because the right atrium receives regurgitant flow in this condition. When interventricular communication exists as part of the defect, a holosystolic murmur is usually present at the mid- to lower left sternal border.

A midsystolic click followed by a late systolic murmur at the apex describes the auscultatory findings of mitral valve prolapse. Mitral valve prolapse occurs more frequently in patients with Down syndrome than in typical individuals, but it generally does not become evident until later in life. Choice A describes rheumatic mitral stenosis, choice D is the murmur of aortic regurgitation, and choice E represents aortic stenosis. These entities do not occur at an increased frequency in patients with Down syndrome.

ANSWER TO QUESTION 547

E (Braunwald, pp. 1646–1647)

Radiation therapy is used to treat several types of malignancies. Historically, the heart and vasculature were subjected to high doses of radiation in patients with lymphoma and in those with cancers of the breast, lung, or esophagus. As a consequence, cardiovascular complications are leading causes of mortality among long-term cancer survivors treated with older radiation techniques. Modern approaches since the 1980s have limited and focused radiation delivery to minimize heart exposure, which has led to a decline in cardiovascular complications.

Radiation therapy may cause myocardial damage and fibrosis, endothelial dysfunction, and arterial intimal hyperplasia. The resulting clinical effects on the cardiovascular system usually do not manifest themselves until long after the irradiation has occurred, often arising 10 to 20 years (or longer) after exposure. Late cardiovascular complications include constrictive pericarditis, proximal coronary artery disease, conduction system disease, valvular disease (especially of the aortic valve), and heart failure due to myocardial fibrosis and restrictive cardiomyopathy. In addition, long-term cancer survivors who have received head and neck irradiation have a two- to threefold increased risk of stroke and transient ischemic attacks.

ANSWER TO QUESTION 548

D (Braunwald, pp. 1580–1585)

Approximately 30% of patients with dilated cardiomyopathy (DCM) have an inherited form of the disease. Most familial examples of DCM fit an autosomal *dominant* pattern of inheritance, although some autosomal recessive and X-linked examples have been identified. Familial DCM appears to result primarily from mutations in genes that code for cytoskeletal, nuclear membrane, or contractile proteins; mitochondrial DNA mutations have also been reported.

Like other forms of DCM, cardiac histologic examination typically demonstrates extensive areas of interstitial and perivascular fibrosis, particularly in the left ventricular subendocardium. There are currently no specific immunologic, histochemical, or ultrastructural markers that can differentiate a genetic cause from other common forms of DCM.

ANSWER TO QUESTION 549

C (Braunwald, p. 1676)

The clinical scenario is most consistent with effusive-constrictive pericarditis, which indicates the simultaneous presence of a hemodynamically significant pericardial effusion and visceral pericardial constriction. This pathophysiology leads to the hemodynamic hallmark of the condition, which is continued elevation of the right atrial pressure following aspiration of the pericardial fluid despite the return of intrapericardial pressure to normal. The causes of this entity are the same as those for chronic constrictive pericarditis. The most common include idiopathic or postviral pericarditis, neoplastic infiltration of the pericardium, mediastinal radiation therapy, and tuberculosis. The physical findings on initial presentation are most consistent with cardiac tamponade, including pulsus paradoxus and jugular venous distention with a prominent *x* descent.

The diagnosis of effusive-constrictive pericarditis is made at cardiac catheterization, with careful hemodynamic monitoring of intrapericardial and right atrial pressures before and after pericardiocentesis. Although intrapericardial pressure returns to baseline (i.e., ~0 mm Hg) after pericardiocentesis, intracardiac pressures do not normalize. Rather, hemodynamic findings convert to a form more consistent with constrictive pericarditis, with a prominent *y* descent in the right atrial pressure tracing and a "dip-and-plateau" pattern in the right ventricular pressure tracing. As might be expected from the pathophysiology, pericardiocentesis provides only partial and transient symptomatic relief; definitive therapy for this condition requires total pericardiectomy.

ANSWERS TO QUESTIONS 550 TO 553

550–B, 551–A, 552–C, 553–D (Braunwald, pp. 1483–1487)

The classic peripheral manifestations of infective endocarditis (IE) are encountered only occasionally in the modern era. Janeway lesions are small, painless, nontender macular lesions on the thenar and hypothenar eminences of the palms and soles. They appear less often on the tips of the fingers or plantar surfaces of the toes. Lesions on the hands and feet blanch with pressure and with elevation of the extremities. In cases of acute valvular infections, the lesions tend to be purple and hemorrhagic.

In contrast, Osler nodes are small, raised, nodular, and tender lesions present most often in the pulp spaces of the terminal phalanges of the fingers. They may also be present on the backs of the toes, the soles, and the thenar and hypothenar eminences. The most characteristic feature of these lesions is their tenderness. Lesions may be fleeting in some cases, disappearing within a few hours after they have developed; however, they usually persist for 4 to 5 days. Although almost completely restricted to the subacute form of endocarditis, Osler nodes are occasionally present in acute valvular infection.

Subungual or splinter hemorrhages in IE are linear (or sometimes flame-shaped) dark red streaks in the proximal nailbed. Distal splinter hemorrhages at the nail tip are nondiagnostic and are frequently caused simply by trauma.

The ocular signs of endocarditis include retinal petechiae and Roth spots. The latter are located in the nerve layer of the retina and appear as hemorrhagic exudates. Histologically, they consist of aggregations of cytoid bodies (perivascular accumulation of lymphocytes with or without surrounding hemorrhage).

Bracht-Wächter bodies represent embolic events to the myocardium in IE that cause a localized inflammatory reaction consisting of collections of lymphocytes and mononuclear cells.

BIBLIOGRAPHY

ANSWERS TO QUESTIONS 554 TO 558

554–C, 555–B, 556–E, 557–A, 558–B (Braunwald, pp. 1593–1594, 1621)

The ECG is often nonspecific in cardiomyopathic disorders, but certain features are common in each of the listed conditions. In chronic Chagas disease, the most common electrocardiographic findings are right bundle branch block, left anterior fascicular block, atrial fibrillation, and premature ventricular complexes. Sarcoidosis has a propensity to infiltrate the atrioventricular (AV) node and bundle of His, producing heart block. Ventricular tachyarrhythmias are also common in this disorder. Apical hypertrophic cardiomyopathy is associated with deeply inverted T waves in the precordial leads. Amyloidosis results in low QRS voltage due to myocardial infiltration by amyloid proteins. Other electrocardiographic features in amyloidosis include rightward axis, first-degree AV block, and a pseudoinfarct pattern in II, III, aVF, and V1–V3. Lyme carditis results in variable degrees of AV block, often with transient diffuse ST-segment and T-wave abnormalities.

ANSWERS TO QUESTIONS 559 TO 562

559–D, 560–C, 561–C, 562–B (Braunwald, pp. 1455–1457)

Artificial cardiac valves consist of mechanical prostheses and bioprosthetic (tissue) valves (Fig. 4.47). Mechanical prostheses are divided into three structural groups: caged-ball, bileaflet, and tilting-disc valves. The Starr-Edwards caged-ball valve was one of the earliest prostheses used and has a long record of predictable performance. However, it has a bulky design, which makes it unsuitable for patients with a small left ventricular cavity or a narrow aortic annulus. Furthermore, the flow characteristics and action of the ball in the cage can generate low-level hemolysis. Tilting-disc valves have largely replaced the caged-ball prostheses, primarily because they are less bulky and have a lower profile. The Medtronic-Hall valve is a type of pivoting disc prosthesis. The bileaflet St. Jude valve has two semicircular discs that pivot between open and closed positions without need for supporting struts. It has a lower transvalvular gradient than either the caged-ball or tilting-disc types and has particularly favorable hemodynamic characteristics in the smaller sizes. Thrombogenicity of the bileaflet St. Jude prosthesis is the lowest of the mechanical valves listed, which makes it an excellent candidate for use in mitral valve replacement in adults.

All of the mechanical prosthetic valves are durable, but they are associated with a risk of thromboembolism, which is greatest in the first postoperative year. Without anticoagulation, the incidence of thromboembolism is three- to sixfold higher than in properly anticoagulated patients. Despite treatment with anticoagulants, the incidence of thromboembolic complications is still 1 to 2 nonfatal events per 100 patient-years. The incidence is significantly higher for prostheses in the mitral as compared to the aortic position. The thrombosis rate of mechanical prostheses in the tricuspid position is extremely high, and for this reason bioprostheses are preferred. Administration of warfarin also carries its own morbidity and mortality, estimated at 2.2 and 0.2 per 100 patient-years, respectively.

The high risk of thromboembolism inherent with the use of mechanical valves was the impetus for the development

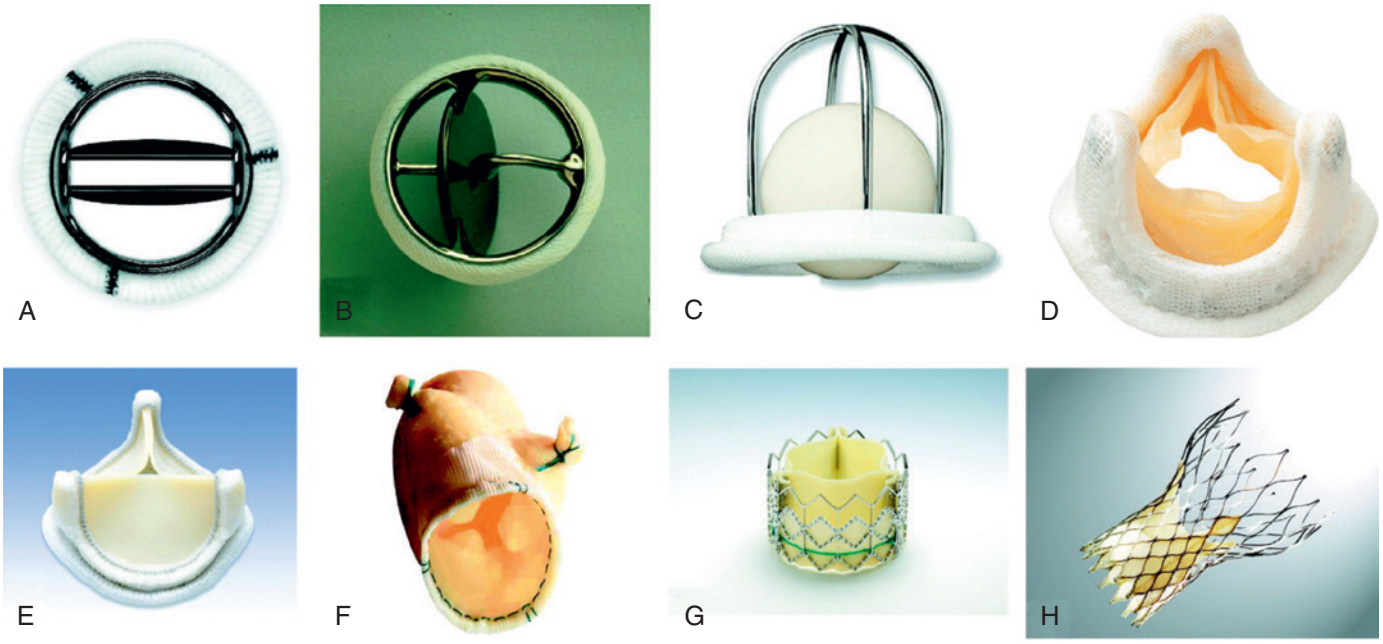

FIG. 4.47 *Types of prosthetic valves. (A) Bileaflet mechanical valve (St. Jude); (B) monoleaflet mechanical valve (Medtronic Hall); (C) caged ball valve (Starr-Edwards); (D) stented porcine bioprosthesis (Medtronic Mosaic); (E) stented pericardial bioprosthesis (Carpentier-Edwards Magna); (F) stentless porcine bioprosthesis (Medtronic Freestyle); (G) percutaneous bioprosthesis expanded over a balloon (Edwards Sapien); (H) self-expandable percutaneous bioprosthesis (CoreValve). From Pibarot P, Dumesnil JG. Prosthetic heart valves: selection of the optimal prosthesis and long-term management.* Circulation. *2009;119:1034.*

of bioprosthetic prostheses. Among the tissue valves are the Hancock and Medtronic Mosaic porcine heterografts and Carpentier-Edwards Magna bovine pericardial valves. Anticoagulation for such valves is generally desirable for the first 3 months postoperatively (especially in the mitral position) while the sewing ring endothelializes. Thereafter, anticoagulants are generally not required. The main limitation of bioprosthetic valves is limited durability over time, and such deterioration occurs more frequently in the mitral than in the aortic position, and more rapidly in younger patients than in the elderly.

Selection of an artificial valve requires consideration of durability, hemodynamic properties, and thromboembolism risk. In general, tissue valves are preferred over mechanical prostheses for patients in whom anticoagulation is difficult or hazardous. Per the 2017 American Heart Association/American College of Cardiology valvular heart disease guideline update, an aortic or mitral mechanical prosthesis is reasonable for patients <50 years old without a contraindication to anticoagulation. A bioprosthesis is recommended for patients >70 years. For patients aged 50 to 70, either a mechanical valve or bioprosthesis is suitable, balancing the risk of bleeding (with a mechanical prosthesis on anticoagulation therapy) versus potential need for repeat intervention for valve deterioration (bioprosthetic valves).

ANSWERS TO QUESTIONS 563 TO 566

563–C, 564–A, 565–A, 566–B (Braunwald, pp. 1674–1675; Table 83.7)

The clinical distinction between constrictive pericarditis (CP) and restrictive cardiomyopathy (RCM) may be difficult. Both RCM and CP may show electrocardiographic changes of left atrial abnormality, diffuse low voltage, and T wave flattening. The presence of atrioventricular block and conduction disturbances favors the diagnosis of RCM, especially infiltrative diseases such as amyloidosis.

In both conditions, right ventricular (RV) and left ventricular (LV) diastolic pressures are elevated, stroke volume and cardiac output are decreased, and LV end-diastolic volume is normal or decreased, with impaired diastolic filling. A diagnosis of RCM is more likely when marked RV systolic hypertension is present (pressure >60 mm Hg) and when LV and RV diastolic pressures at rest, or during exercise, differ by more than 5 mm Hg. Some patients with RCM may display hemodynamics that are indistinguishable from those seen with CP, including sustained and complete equilibration of RV and LV diastolic pressures, as well as the presence of a "dip-and-plateau" pattern in the ventricular waveform. However, simultaneous RV and LV systolic pressure measurements can aid in the differentiation of these conditions. Unlike normal individuals and those with RCM, patients with CP often demonstrate marked discordance of RV and LV systolic pressure during inspiration.[1,2] Specifically, with the onset of inspiration, LV systolic pressure declines with a reciprocal increase in RV systolic pressure (Fig. 4.48).

Echocardiography in restrictive cardiomyopathy may reveal abnormally thickened ventricular myocardium, often with a "sparkling" appearance if amyloidosis is present. Other useful differentiating features on echocardiography include

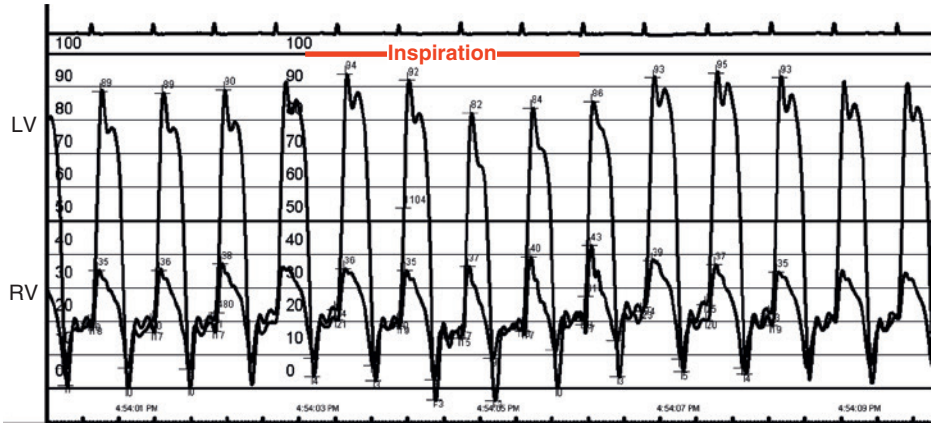

FIG. 4.48

a diastolic septal "bounce" and a normal or increased tissue Doppler medial mitral annular E′ velocity in constriction, in distinction to a blunted E′ value (<8 cm/s) in RCM.[3] Chest computed tomography and magnetic resonance imaging are also helpful in distinguishing these entities, demonstrating a thickened pericardium in >80% of patients with constrictive pericarditis, but not in patients with restrictive cardiomyopathy.[4]

ANSWERS TO QUESTIONS 567 TO 571

567–A, 568–C, 569–C, 570–D, 571–B (Braunwald, pp. 1867–1869, 1871)

Cardiac myxomas and papillary fibroelastomas are two of the most common primary tumors of the heart. They are benign and do not undergo malignant transformation. Papillary fibroelastomas are the most common primary tumors found on cardiac valves. These lesions are usually small, frond-like structures that consist of a collagen core surrounded by elastic fibers and loose connective tissue. They are most often detected as an incidental finding on echocardiography or at postmortem examination. Papillary fibroelastomas are often clinically insignificant, but there is the potential for embolization or valve orifice obstruction if the tumor is large. Anticoagulation does not appear to protect against embolic risk. Surgical resection of these tumors is generally recommended, especially those in left-sided locations, to prevent thromboemboli. Resection can usually be performed with valve-sparing techniques. There is no known familial syndrome associated with papillary fibroelastomas.

Approximately 10% of myxomas are familial, transmitted in an autosomal dominant pattern. Sporadic myxomas most commonly attach to the interatrial septum; valvular origins for myxoma are rare. Myxomas have a high risk of distal embolization due to the friable nature of the tumor. Surgical resection is recommended to avoid new or recurrent complications, including progressive constitutional symptoms, embolism, and valvular obstruction.

ANSWERS TO QUESTIONS 572 TO 575

572–C, 573–B, 574–D, 575–A (Braunwald, pp. 1835–1838, 1843–1845)

Unfractionated heparin (UFH) has been the historic acute therapy for pulmonary embolism. UFH is a porcine- or bovine-derived glycosaminoglycan that acts by binding to antithrombin with subsequent inhibition of the procoagulant factors thrombin (IIa), Xa, IXa, XIa, and XIIa. Heparin prevents additional thrombus formation and promotes endogenous fibrinolysis; however, it does not directly dissolve formed clots. For patients at average bleeding risk, a weight-based intravenous bolus of 80 units/kg is begun, followed by 18 units/kg/h by continuous infusion. The activated partial thromboplastin time should be maintained between 1.5 and 2.5 times the control value (typical therapeutic range is 60 to 80 seconds) for effective treatment. The major risk of heparin use is hemorrhage. Thrombocytopenia, osteopenia, and elevated liver enzymes can all complicate heparin therapy. Protamine may be used to reverse the anticoagulant effects of unfractionated heparin.

Low-molecular-weight heparin (LMWH) formulations are now the preferred parenteral therapy for acute management of PE in hemodynamically stable patients. LMWH has greater bioavailability than unfractionated heparin, has a more predictable dose response, and does not require serial measurements of the aPTT. Compared with UFH, LMWH results in reduced mortality, less bleeding, and fewer recurrent thromboemboli. If needed, the effectiveness of LMWH can be monitored by measuring the plasma heparin (anti-factor Xa) level. Both unfractionated heparin and LMWHs can inhibit the secretion of aldosterone, particularly with prolonged administration. This effect can result in hyperkalemia, especially in patients

with renal failure or diabetes. Alternatives to LMWH include subcutaneous fondaparinux, a factor Xa inhibitor with similar benefits and risks, and the oral factor Xa inhibitors rivaroxaban and apixaban. Dabigatan (an oral direct thrombin inhibitor) and edoxaban (another oral factor Xa inhibitor) are approved to treat acute venous thromboembolism following initial treatment with a parenteral anticoagulant.

Fibrinolytic therapy (alteplase) physically dissolves anatomically obstructing pulmonary arterial thrombus and improves pulmonary capillary blood flow, but is associated with a substantial risk of bleeding complications. High-risk subgroups who may benefit from fibrinolytic therapy include patients with massive pulmonary embolism who have moderate-to-severe right ventricular dysfunction and elevation of cardiac biomarkers. Unlike in acute ST-segment elevation myocardial infarction, fibrinolytic therapy for PE may be efficacious when used up to 2 weeks after the onset of symptoms.

ANSWERS TO QUESTIONS 576 TO 580

576–C, 577–A, 578–D, 579–A, 580–B (Braunwald, pp. 1591–1594, 1597–1598)

Hemochromatosis and amyloidosis are both infiltrative diseases. Hemochromatosis results in deposition of excessive iron within the myocardium and other organs, including the liver, pancreas, and gonads. It most commonly arises on a hereditary basis (mutations in *HFE* gene, autosomal recessive transmission), from other causes of increased iron absorption (e.g., states of ineffective erythropoiesis), or as a result of multiple blood transfusions.

Cardiac amyloidosis refers to the deposition of misfolded products of various protein precursors in the heart. Light-chain (AL) amyloidosis results from production of a protein derived from immunoglobulin light chains by plasma cells, frequently in the setting of plasma cell dyscrasias such as multiple myeloma. A familial form of amyloidosis is inherited in an autosomal dominant fashion in which a mutant version of the hepatically expressed protein transthyretin represents the amyloid precursor protein. The previously termed "senile" form of amyloidosis is due to deposition of amyloid protein derived from normal (wild-type) transthyretin in older individuals. Secondary (AA) amyloidosis may arise in systemic inflammatory conditions, resulting in organ amyloid deposits derived from the inflammatory protein serum amyloid A, but this condition rarely involves the heart.

Because of the infiltrative nature of these conditions, each initially leads to a "stiffened" myocardium and usually presents as a restrictive cardiomyopathy. In later stages, however, dilatation of the ventricles may ensue. Although arrhythmias are common in both conditions, rhythm disorders are not usually prominent initial symptoms. The ECG in hemochromatosis usually shows diffuse ST-segment and T wave abnormalities as well as supraventricular arrhythmias. Abnormal rhythms, especially atrial fibrillation, are also common in amyloidosis, in addition to electrocardiographic findings of low-voltage QRS complexes and pseudoinfarction patterns.

If diagnosed early, the cardiomyopathy of hemochromatosis may be reversed with phlebotomy and chelating agents. Both computed tomography and cardiovascular magnetic resonance imaging have been used to detect early subclinical myocardial involvement at a time when therapy is most effective.[1] Cardiac amyloidosis generally carries a grim prognosis, but progress has been made at improving longer-term survival. For example, in AL amyloidosis, the proteasome inhibitor bortezomib has been successful at controlling the underlying plasma cell dyscrasia, with normalization of serum light chains and improvement in heart failure symptoms.[2] Cardiac transplantation has been performed for AL amyloidosis, however, outcomes tend to be poor due to progression of amyloidosis in other organs or recurrence in the transplanted heart. Some patients with mutant transthyretin amyloidosis may benefit from liver or combined liver-heart transplantation.

ANSWERS TO QUESTIONS 581 TO 585

581–A, 582–B, 583–B, 584–A, 585–B (Braunwald, pp. 1445–1446, 1450)

Tricuspid stenosis (TS) is most commonly rheumatic in origin. It almost never occurs as an isolated lesion, but rather accompanies rheumatic mitral valve disease. Typical findings include fatigue, right-sided heart failure with hepatomegaly, abdominal swelling due to ascites, and anasarca. Auscultation usually reveals signs of mitral stenosis (MS), and these often overshadow those of TS. The diastolic murmur of TS is heard best along the lower left sternal border at the fourth intercostal space and is usually softer, higher pitched, and shorter in duration than the murmur of MS. The management of severe TS is surgical and requires valvulotomy or valve replacement when the orifice is less than ~2 cm^2. In general, tissue valves are used preferentially in the tricuspid position because of the high risk of thrombosis with mechanical prostheses.

The most common form of pulmonic stenosis (PS) is congenital. A rarer form results from carcinoid plaques. The latter cause constriction of the pulmonic valve ring, retraction and fusion of the cusps, and PS with or without pulmonic regurgitation. Carcinoid heart disease can also involve the tricuspid valve, but most commonly leads to tricuspid regurgitation.

Most adults with mild to moderate PS are asymptomatic, and it is only the more severe forms that result in dyspnea and fatigue. Patients with advanced PS may develop secondary tricuspid regurgitation and right ventricular failure.

In the majority of patients, valvular PS is a stable or slowly progressive disease. Physical examination is notable for a systolic thrill along the left upper sternal border, a prominent systolic ejection murmur heard at the location of the thrill, and often an associated ejection click. In contrast to the inspiratory increase in most right-sided cardiac sounds, the

intensity of the pulmonic click in PS decreases with inspiration. Echocardiography can define the lesion, and Doppler imaging allows accurate estimation of the gradient across the valve. In adults, percutaneous balloon valvuloplasty for advanced valvular PS is safe and effective and is the treatment of choice.

ANSWERS TO QUESTIONS 586 TO 589

586–C, 587–D, 588–B, 589–B (Braunwald, pp. 1112–1114; Fig. 58.4)

Calcium channel blockers and prostacyclin are two forms of vasodilator therapy used in the chronic management of patients with idiopathic (group 1) pulmonary arterial hypertension (PAH). They are prescribed to carefully selected patients with hemodynamic guidance. Up to 20% of patients with idiopathic PAH show a vasoreactive response and demonstrate a dramatic drop in pulmonary artery pressure and resistance with high-dose calcium channel blockers.[1] Such patients have improved quality of life and survival compared with control subjects and with those who do not demonstrate a dramatic hemodynamic response. Potential adverse effects of calcium channel blockers in patients with PAH include a right ventricular negative inotropic effect and reflex sympathetic stimulation with tachycardia.

Chronic intravenous epoprostenol (prostacyclin) administration has been shown to improve symptoms, quality of life, and survival in patients with idiopathic PAH.[2] It also demonstrates antithrombotic effects that may be of benefit in the management of the thrombo-occlusive component of PAH and may help to restore the integrity of the pulmonary vascular endothelium. Epoprostenol therapy is, however, cumbersome because it requires a surgically implanted central venous catheter and an infusion pump system. The prostacyclin analogs iloprost (by inhalation) and treprostinil (subcutaneously or by inhalation) improve symptoms and are more easily administered, but evidence of survival benefit is lacking.[3]

Additional agents are available that improve the quality of life in patients with group 1 PAH. The phosphodiesterase type 5 inhibitors sildenafil, tadalafil, and vardenafil reduce pulmonary arterial pressure, improve exertional capacity, and are well tolerated. Additionally, a group of endothelin receptor blockers (bosentan, ambrisentan, macitentan) improve hemodynamics, symptoms, and stamina in this condition.[4] Side effects of this group include peripheral edema and hepatic toxicity. More recently, riociguat, a soluble guanylate cyclase stimulator, has been shown to improve exercise capacity and functional class in patients with PAH.[5]

ANSWERS TO QUESTIONS 590 TO 593

590–C, 591–B, 592–A, 593–B (Braunwald, pp. 1674–1675; Table 83.7; see also Answers to Questions 563 to 566)

The clinical and hemodynamic features of restrictive heart disease such as those caused by cardiac amyloidosis may be very similar to those of chronic constrictive pericarditis. Endomyocardial biopsy, computed tomography, and magnetic resonance imaging may be useful in differentiating the two diseases. The typical hemodynamic feature present in both conditions is the deep and rapid early decline in ventricular pressure at the onset of diastole, followed by a rapid rise to a plateau in early diastole. Patients with restrictive cardiomyopathy may have left ventricular filling pressures that exceed RV filling pressures by >5 mm Hg (whereas there is <5 mm Hg difference between them in pericardial constriction), and this difference can be accentuated by exercise. Furthermore, the pulmonary artery systolic pressure may be >60 mm Hg in patients with restrictive cardiomyopathy, but is usually lower in constrictive pericarditis. As a result, the plateau of the RV diastolic pressure is usually greater than one-third of the peak RV systolic pressure in patients with constrictive pericarditis, while it is more commonly less than one-third in patients with restrictive cardiomyopathy.

In the atrial tracings, the dip-and-plateau sign manifests as a prominent *y* descent followed by a rapid rise in pressure. The *x* descent may also be prominent, and the combination results in the characteristic M-shaped waveform in the atrial pressure tracing.

ANSWERS TO QUESTIONS 594 TO 597

594–D, 595–B, 596–C, 597–A (Braunwald, pp. 1393–1394)

The natural history of aortic stenosis (AS) has been described in a cohort of patients who did not undergo aortic valve surgery. Patients whose only symptom of AS was angina had an average survival of 3 to 5 years. Those with syncope had a shorter average survival of 2 to 3 years. Those with signs and symptoms of congestive heart failure had the worst prognosis—an average survival of only 1.5 to 2 years. Because of such reduced longevity, patients with AS and any of these symptoms should be referred for surgical correction,

especially if symptoms of heart failure are present. Palpitations are not a marker for adverse survival in patients with AS.

BIBLIOGRAPHY

Nishimura RA, Otto CM, Bonow RO, et al. 2014 AHA/ACC guideline for the management of patients with valvular heart disease: a report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines. *J Am Coll Cardiol*. 2014;63:e57–e185.

ANSWERS TO QUESTIONS 598 TO 601

598–A, 599–B, 600–C, 601–A (Braunwald, p. 1507; Table 73G-1)

The American Heart Association (AHA) has published a set of consensus recommendations for antibiotic prophylaxis for the prevention of infective endocarditis (IE).[1] This statement simplified older guidelines and focused on prophylaxis for patients at the highest risk of complications from IE. High-risk patients are considered to be those with (1) prosthetic heart valves, (2) prior endocarditis, (3) specific types of congenital heart disease (unrepaired cyanotic lesions, repaired congenital lesions with residual defects, or during the first 6 months after repair with prosthetic material or device), and (4) cardiac transplant recipients with valvulopathy. Routine gastrointestinal or genitourinary tract procedures are not indications for antibiotic prophylaxis unless there is an active gastrointestinal or genitourinary tract infection in a patient with one of these high-risk cardiac conditions. These recommendations were incorporated in the 2014 American College of Cardiology/AHA valvular heart disease guidelines.[2]

The first patient in this question is at high risk owing to the prosthetic mitral valve, but prophylaxis is not recommended for routine gastrointestinal procedures such as colonoscopy. The second and third patients are at high risk owing to the prosthetic valves, and prophylaxis is recommended. The third patient is penicillin-allergic, so an alternative regimen such as clindamycin should be administered instead. The fourth patient is not at high risk, and prophylaxis for gastrointestinal procedures is not recommended unless there is active infection.

ANSWERS TO QUESTIONS 602 TO 606

602–B, 603–B, 604–C, 605–A, 606–D (Braunwald, pp. 1538–1541, 1553–1555)

Complete atrioventricular canal defects (also known as endocardial cushion defects) comprise a group of abnormalities in which the common features are (1) absence of the membranous and muscular atrioventricular septum (causing the atrioventricular [AV] valves to appear at the same level on echocardiography), (2) inlet/outlet disproportion resulting in an elongated left ventricular outflow tract (producing a "gooseneck" deformity on angiography), (3) lateral rotation of the posteromedial papillary muscle, and (4) abnormal configuration of the AV valves (e.g., the left AV valve is trileaflet with a "cleft" appearance). Infants usually present in the first year of life with a history of poor weight gain and frequent respiratory infections, and heart failure is common. On physical examination, several murmurs may be present, including a holosystolic murmur along the lower left sternal border due to the VSD, a holosystolic murmur at the apex due to mitral regurgitation, and a right ventricular (RV) outflow tract systolic murmur. Because the direction of intracardiac shunting is left to right, cyanosis is not typical. Typical electrocardiographic findings include left-axis deviation due to left anterior fascicular block and incomplete right bundle branch block. Echocardiography is usually diagnostic for this condition.

In complete transposition (d-transposition) of the great arteries (d-TGA), the aorta arises from the morphologic right ventricle and the pulmonary artery arises from the morphologic left ventricle. This anatomic arrangement results in two separate and parallel circulations. Some communication between the pulmonary and systemic circulations must exist after birth to sustain life. Almost all patients have an interatrial communication, two-thirds have a patent ductus arteriosus (PDA), and one-third have an associated VSD. The typical clinical manifestations are dyspnea and cyanosis, progressive hypoxemia, and congestive heart failure. Cardiac murmurs are absent or insignificant in 30% to 50% of patients with d-TGA and an intact ventricular septum. In infants with d-TGA and a large PDA, fewer than half have the typical continuous murmur of the aortopulmonary connection. Electrocardiographic findings include right-axis deviation, right atrial enlargement, and RV hypertrophy. Echocardiography is usually diagnostic for identifying the abnormal great-vessel relationship and accompanying abnormalities. An arterial switch operation is the treatment of choice.

ANSWERS TO QUESTIONS 607 TO 611

607–D, 608–C, 609–C, 610–A, 611–B (Braunwald, pp. 1521, 1527)

Noonan syndrome is a relatively common (1 per 1000) genetic disorder with autosomal dominant inheritance. About one-half of patients have mutations in the *PTPN11* gene on chromosome 12. This syndrome is characterized phenotypically by short stature, a unique facial appearance, mild mental retardation, webbing of the neck, cryptorchidism, and renal anomalies. Approximately half of all patients with Noonan syndrome have congenital heart disease, the most common lesion of which is valvular pulmonic stenosis. The ECG commonly displays left anterior fascicular block. Approximately 20% of patients with Noonan syndrome

have an accompanying atrial septal defect or hypertrophic cardiomyopathy.

The *LEOPARD* syndrome is a rare, single-gene complex of congenital malformations. The acronym LEOPARD symbolizes the main components of the syndrome: L, lentigines; E, electrocardiographic conduction defects; O, ocular hypertelorism; P, pulmonic valve stenosis; A, abnormalities of the genitals; R, retardation of growth; and D, deafness. Eighty percent of patients display lentigines, whereas deafness and abnormalities of the genitals occur in about 20%. The most common structural cardiac feature is pulmonic stenosis, which may exist as an isolated anomaly or in combination with aortic stenosis. The most common electrocardiographic conduction defects are PR-segment prolongation, QRS complex widening, left anterior fascicular block, and complete heart block. The most striking physical feature of the syndrome is the presence of small, dark lentigines, which are concentrated over the neck and upper extremities. LEOPARD syndrome is transmitted in an autosomal dominant fashion, with cardiovascular abnormalities in at least 95% of affected patients.

Kartagener syndrome is an autosomal recessive disorder, the primary defect of which has been elucidated by electron microscopic investigation of cilia from affected individuals' bronchial mucosa or sperm. Dynein arms, which are protein structures that normally form cross-bridges between adjacent microtubules in cilia and sperm tails, are abnormal in this disorder. Several mutations capable of producing the syndrome are recognized, and in each case, the mutant gene disrupts the synthesis either of the dynein protein itself or of a protein that binds dynein to the microtubules. Clinically, the syndrome consists of the triad of sinusitis, bronchiectasis, and situs inversus with dextrocardia. Cases of Kartagener syndrome usually come to attention in infancy due to recurrent upper respiratory infections or pneumonia, and development of classic sinusitis and chronic bronchiectasis occurs as childhood progresses. The majority of individuals with Kartagener syndrome have dextrocardia as the only cardiac manifestation, which leads to an abnormal 12-lead ECG, but no other clinical consequences. On rare occasions, associated cardiac anomalies may be present, including transposition of the great vessels.

Holt-Oram syndrome is a rare autosomal dominant disorder. The classic clinical manifestation is the simultaneous occurrence of congenital heart disease and an upper limb deformity. The most common cardiovascular abnormality is an atrial septal defect of the secundum type, with ventricular septal defect being the next most common. Electrocardiographic abnormalities are frequently present as well and may include first-degree atrioventricular block, right bundle branch block, and bradycardia. Deformities of the forearm and hand are the most apparent features of Holt-Oram syndrome (e.g., hypoplasia or triphalangeal abnormalities of the thumbs). The most specific upper extremity finding, an abnormal scaphoid bone or accessory carpal bones or both, may be detected by wrist radiography. One form of Holt-Oram syndrome has been linked to mutations in the *TBX5* gene located on chromosome 12. *TBX5* is a member of the T-box family of transcription factors that critically regulate morphogenesis in the developing embryo.

Bhatt AB, Kuehl K, Alpert J, et al. Congenital heart disease in the older adult: a scientific statement from the American Heart Association. *Circulation*. 2015;131:1884–1931.

ANSWERS TO QUESTIONS 612 TO 615

612–C, 613–A, 614–B, 615–D (Braunwald, pp. 1487, 1593, 1595–1596, 1856)

Extracardiac manifestations of systemic disorders that also have major cardiac involvement may provide important clues to the underlying diagnosis. One example is infective endocarditis, in which specific lesions may appear in the skin and the eyes. In the skin, these include petechiae, Osler nodes, Janeway lesions, Roth spots, subungual ("splinter") hemorrhages, and embolic infarcts of the digits, as may occur with *Staphylococcus aureus* infection of the left-sided valves; the last are illustrated in part *A* in the figure. Osler nodes are small, raised, nodular, and painful red to purple lesions that appear in the pulp spaces of the terminal phalanges of the fingers. Janeway lesions are small, irregular, flat, and nontender macules occurring most often on the thenar and hypothenar eminences of the hands and soles. Roth spots on the retina have the appearance on funduscopic examination of a "cotton wool" exudate and consist of aggregations of cytoid bodies. All of these peripheral stigmata of infective endocarditis have become uncommon in the modern era.[1]

Amyloidosis is a systemic illness in which unique protein-derived fibrils are deposited in a variety of organs. Cardiac involvement is common in primary (AL) amyloidosis (often a consequence of multiple myeloma) and in familial amyloidosis (an autosomal dominant condition that typically results from a mutated form of the protein transthyretin).[2] Cardiac sequelae include restrictive cardiomyopathy with diastolic dysfunction, conduction abnormalities, systolic dysfunction, and orthostatic hypotension. Dermatologic findings include small papules on the face, scalp, neck fold, or intertriginous folds. In addition, small, smooth, and yellowish papules may be seen in the area around the eyes and be mistaken for xanthomas. Amyloid infiltration can result in macroglossia, as shown in part *B*.

Fabry disease is a sex-linked disorder that is due to a deficiency of the enzyme alpha-galactosidase A. The disorder is characterized by the accumulation of glycosphingolipid within the myocardium, skin, and kidneys. Systemic hypertension, mitral valve prolapse, renovascular hypotension, and congestive heart failure are all common clinical manifestations. Fabry disease may also cause restrictive cardiomyopathy. Ocular signs in the disorder are common. Approximately 90% of patients have corneal opacities, whereas two-thirds of patients have conjunctival vessel tortuosity as illustrated in part *C* of the figure.[3] Hypertensive cardiovascular disease, renal failure, and cerebrovascular disease are the major causes of death in this disorder. Purified human alpha-galactosidase A is available as an intravenous therapeutic option, which reduces tissue storage of the offending glycosphingolipid.

Progressive systemic sclerosis, or scleroderma, presents as tightening and thickening of the skin, with Raynaud phenomenon occurring in almost all patients.[4] Cardiac involvement is common and is a frequent cause of death, second only to involvement of the kidneys as a factor shortening survival. Scleroderma heart disease is primarily a myocardial process, leading to vascular insufficiency and fibrosis in the small vessels of the heart, which produces cardiomyopathy with congestive heart failure, conduction system abnormalities, and/or ventricular dysrhythmias. Pericardial involvement with fibrinous pericarditis is common,

as is the development of pulmonary hypertension due to intrinsic pulmonary vascular disease or interstitial fibrosis. The CREST variant of this syndrome describes patients with calcinosis, Raynaud phenomenon, esophageal dysmotility, sclerodactyly, and telangiectasia. Recurrent painful ulcerations of the fingertips, which may become infected, are a common problem in this disorder and are illustrated in part *D*.

ANSWERS TO QUESTIONS 616 TO 619

616–A, 617–B, 618–B, 619–C (Braunwald, p. 1527; see also Answers to Questions 607 to 611)

The Turner and Noonan syndromes share several superficial features, including short stature, webbing of the neck, skeletal anomalies, renal abnormalities, and congenital heart disease. Because of these clinical similarities, Noonan syndrome is frequently referred to as male Turner syndrome or as Turner phenotype with normal chromosomes. However, there are several striking genetic and clinical differences that can readily distinguish these two disorders. Turner syndrome occurs exclusively in females. In about 50% of patients, the karyotype is 45,XO. The remaining patients are mosaics with various other X chromosome abnormalities. Most fetuses with the 45,XO form of Turner syndrome die in utero. Of those who survive, cardiovascular abnormalities occur in 35% to 50%. Coarctation of the aorta is the most common cardiovascular lesion. Other abnormalities include bicuspid aortic valve, hypertrophic cardiomyopathy, atrial septal defect, mitral valve prolapse, and dextrocardia. Stenosis of the pulmonic valve is rarely seen in Turner syndrome, in contrast to Noonan syndrome.

Noonan syndrome appears physically similar to Turner syndrome; however, as indicated in Answers to Questions 607 to 611, affected patients have a unique facial appearance, with hypertelorism, strabismus, small chin, and low-set ears. It is inherited as an autosomal dominant trait and, in contrast to Turner syndrome, both males and females are susceptible to this condition; the karyotype in both sexes is normal. In many families, the genetic abnormality maps to chromosome 12q24; about half have a mutation in the *PTPN11* gene in that region. Approximately 50% of patients with Noonan syndrome have congenital heart disease; the most common lesion is valvular pulmonary stenosis, occurring in about 60% of patients. Characteristically, the annulus of the pulmonary valve is normal, but the leaflets are thickened and immobile. Other findings include atrial septal defect and hypertrophic cardiomyopathy.

ANSWERS TO QUESTIONS 620 TO 624

620–C, 621–A, 622–B, 623–A, 624–A (Braunwald, pp. 1544–1548)

The two-dimensional echocardiogram in part *A* of the figure displays an apical, four-chamber view of tricuspid atresia, demonstrating a dense band in the tricuspid annulus and an enlarged left ventricle. This anomaly is marked by the absence of the tricuspid orifice with an atrial septal defect, usually with hypoplasia of the right ventricle, and communication between the ventricles, typically via a ventricular septal defect. In 60% to 70% of patients with this condition, the great arteries have normal relationships; the remainder have d-transposition of these vessels. In addition, pulmonic stenosis or atresia may be present. Clinically, the marked diminution in pulmonary blood flow usually leads to severe cyanosis. In those infants in whom transposition coexists with a ventricular septal defect and an unobstructed pulmonary outflow tract, torrential pulmonary blood flow will occur, leading to heart failure rather than cyanosis as the predominant problem. The majority of infants with tricuspid atresia have pulmonary hypoperfusion and the clinical picture of cyanosis, with electrocardiographic findings of left ventricular hypertrophy, left-axis deviation, and right atrial enlargement.

Echocardiographic examination in this disorder is usually diagnostic. At cardiac catheterization, the right ventricle cannot be entered from the right atrium. When the great arteries are normally related, pulmonary blood flow is maintained via a ventricular septal defect or patent ductus arteriosus. However, in complete transposition, the pulmonary artery blood flow is derived directly from the left ventricle. Functional correction of tricuspid atresia has been accomplished by the Fontan procedure, which consists of construction of a prosthetic conduit between the right atrium and pulmonary artery and closure of the intra-atrial communication.

The two-dimensional echocardiogram in part *B* is a parasternal long-axis view of tetralogy of Fallot, which demonstrates (1) the aorta overriding the interventricular septum and (2) a ventricular septal defect. The two other components that comprise this malformation are (1) right ventricular (RV) outflow obstruction and (2) RV hypertrophy. The clinical presentation in tetralogy of Fallot is determined principally by the degree of obstruction to pulmonary blood flow. Infants with tetralogy of Fallot become symptomatic and cyanotic before the age of 1 year. There is a direct correlation between the time of onset of symptoms and the severity of pulmonary outflow tract obstruction. Intense cyanotic spells related to sudden increases in venoarterial shunting and simultaneous decreases in pulmonary blood flow occur between 2 and 9 months of age and may be life threatening.

Physical examination of infants with tetralogy of Fallot usually reveals varying degrees of underdevelopment and cyanosis, commonly with clubbing of the terminal digits within the first year of life. An RV impulse and systolic thrill

may often be appreciated along the left sternal border. A systolic flow murmur across the pulmonic valve is often present, and the intensity and duration of this murmur vary inversely with the severity of the pulmonic outflow tract obstruction. The ECG usually shows RV hypertrophy. On chest radiography, a normal-sized boot-shaped heart with prominence of the right ventricle and a concavity in the region of the underdeveloped RV outflow tract is typical. Echocardiographic findings are diagnostic. Cardiac catheterization is used to delineate the course of the pulmonary arteries and collateral channels when patients have pulmonary atresia as part of the syndrome and to document the coronary artery anatomy before surgical repair. Coronary variations in this disorder include the abnormal origin of the anterior descending artery from the right coronary artery or a single right or left coronary artery giving rise to the remaining coronary vessels.

The management of tetralogy of Fallot consists of total correction of the anomaly, with early definitive repair being advocated in most centers, often during the first 6 months. Pulmonary arterial size is the single most important determinant in evaluating a patient for primary repair. For those in whom marked hypoplasia of the pulmonary arteries is present, balloon dilatation may be used in a palliative manner to allow the infant to survive until an older age, at which time total correction may be carried out at lower risk.

ANSWERS TO QUESTIONS 625 TO 629

625–A, 626–A, 627–B, 628–B, 629–D (Braunwald, pp. 1641–1643, 1646–1647)

Radiation therapy and chemotherapeutic agents both have potentially serious cardiac adverse effects. Cardiac exposure may occur as a result of therapeutic irradiation of lung, breast, or esophageal cancers or mediastinal radiation for lymphomas. All cardiac structures are susceptible to radiation damage, especially the pericardium, but also the myocardium, coronary arteries, conduction system, and valves. The effects of radiation on the pericardium may be acute (e.g., hemorrhagic effusions) or delayed for several years (fibrosis with constrictive pericarditis). Radiation therapy is also a cause of premature coronary artery disease (CAD). Retrospective studies have demonstrated that children treated with radiation therapy for Hodgkin disease have a significantly increased risk of developing symptomatic CAD at an early age. Radiation-induced myocardial fibrosis is common and may lead to restrictive cardiomyopathy. Radiation effects on the conduction system may cause sinus node disease and atrioventricular block. Radiation exposure of the aortic valve and papillary muscles has been implicated as a cause of regurgitation of the aortic and mitral valves.

As described in the Answer to Question 544, anthracycline chemotherapeutic agents can have an acute direct toxic effect on the myocardium, resulting in ventricular and supraventricular dysrhythmias as well as conduction system blocks. More commonly, cumulative exposure to anthracyclines results in a chronic cardiomyopathy, especially at a total cumulative dose >400 mg/m^2. Rare cases of acute myocarditis-pericarditis within 2 weeks of anthracycline therapy have been described.

Aortic dissection is not associated with these antineoplastic therapies.

SECTION V QUESTIONS

(CHAPTERS 88 TO 99)

Cardiovascular Disease in Special Populations; Cardiovascular Disease and Disorders of Other Organs

David D. Berg and Leonard S. Lilly

Directions:

For each question below, select the ONE BEST response.

QUESTION 630

A 24-year-old man who is training for the Olympic decathlon team experiences a presyncopal event and is referred for evaluation. He has been training aggressively for the past 2 years and, aside from occasional single palpitations, has not noticed any prior lightheadedness, other cardiac symptoms, or physical limitations. He has no history of hypertension and his family history is free of premature coronary disease or sudden cardiac death (SCD). On physical examination his blood pressure and heart rate are normal. A grade II/VI rough crescendo-decrescendo systolic murmur is auscultated along the left sternal border, which becomes louder when the patient stands. The patient is anxious to return to his training regimen. Which of the following statements is TRUE?

A. Voltage criteria for left ventricular hypertrophy on this patient's electrocardiogram is sufficient to establish the diagnosis of hypertrophic cardiomyopathy (HCM) and should prohibit him from resuming competitive athletics
B. An echocardiographic end-diastolic septal wall thickness of 14 mm would be diagnostic of HCM
C. Persistent left ventricular hypertrophy by echocardiography 6 months after cessation of exercise is consistent with genetic HCM
D. A maximum oxygen uptake of 50 mL/kg/min on cardiopulmonary exercise testing is more consistent with HCM than "Athlete's Heart"
E. Anomalous origin of the left coronary artery is a more common cause of SCD in young athletes than HCM

QUESTION 631

A 66-year-old man with chronic kidney disease (CKD) is referred for office evaluation after a recent admission for an acute coronary syndrome (ACS). Which of the following statements is correct concerning CKD and cardiovascular disease?

A. Patients with CKD are at increased risk of bleeding but decreased risk of thrombotic events when compared with normal individuals
B. The outcomes of patients with CKD who present with ACSs are similar to those of patients with normal renal function
C. Patients with CKD who present to the hospital with chest pain comprise a relatively low-risk group of ACSs, with a cardiac event rate of <5% at 30 days
D. Renal dysfunction is the most significant independent predictor of mortality of patients in coronary care units
E. Uremia is associated with enhanced platelet aggregation

QUESTION 632

A 20-year-old female student presents to the emergency department with recent malaise, myalgias, fevers, sweats, and claudication of the right lower extremity and left arm. On physical examination the blood pressure is 160/90 mm Hg in the right arm and 120/85 mm Hg in the left arm. The left radial and right femoral pulses are diminished and a left-sided subclavian bruit is auscultated. The erythrocyte sedimentation rate is markedly elevated. Which of the following statements about this condition is TRUE?

A. Arterial biopsy would reveal a polymorphonuclear infiltrate
B. Aortic aneurysm formation is more common than arterial stenoses
C. This condition is 10 times more common in women than men
D. Claudication occurs more commonly in the lower extremities than the upper extremities
E. Coronary vasculitis is not typical in this syndrome

QUESTION 633

A 58-year-old woman complains of a new-onset severe headache, jaw pain with chewing, and temporal artery

tenderness. Laboratory examination shows an erythrocyte sedimentation rate (ESR) of 80 mm/h. Which of the following is TRUE regarding treatment of this condition?

A. Corticosteroids should not be administered until biopsy evidence confirms the diagnosis
B. Clinical improvement with appropriate treatment generally occurs over several weeks
C. Anti-tumor necrosis factor (TNF) therapies have been shown to be beneficial in this condition
D. In the absence of contraindications, low-dose aspirin should be prescribed
E. Normalization of the ESR is a reliable indicator of treatment response

QUESTION 634

A 35-year-old woman with hypertension is considering pregnancy. She is currently taking lisinopril 10 mg daily. Which of the following statements is correct?

A. She should remain on her current antihypertensive regimen before and during pregnancy
B. An angiotensin receptor blocker should be substituted
C. Labetalol should be avoided during pregnancy
D. Women with preexisting hypertension have a higher incidence of preeclampsia compared with those with new-onset hypertension during pregnancy
E. Antihypertensive therapy is effective in preventing preeclampsia during pregnancy

QUESTION 635

A 58-year-old woman in good health presents for evaluation. She is concerned about cardiovascular risk because her father sustained a myocardial infarction at age 70. Which of the following statements about heart disease in women is NOT correct?

A. Cardiovascular disease is the leading cause of death in women
B. In recent decades, age-adjusted cardiovascular mortality in the United States has increased in women while it has declined in men
C. Coronary heart disease presents approximately 10 years later in women than in men
D. Cardiovascular disease is twice as common in women with diabetes compared with nondiabetics
E. Hormone replacement therapy with estrogen does not reduce the risk of cardiac events in postmenopausal women

QUESTION 636

A 36-year-old woman with no prior history of cardiac disease develops exertional dyspnea and orthopnea 1 month after delivering a healthy full-term infant. Echocardiography demonstrates a dilated left ventricle with globally reduced contractile function. Which of the following statements regarding peripartum cardiomyopathy (PPCM) is TRUE?

A. Symptoms of PPCM always arise during the last month of pregnancy or within 1 week after delivery
B. Clinical and hemodynamic findings in PPCM are indistinguishable from those of other forms of dilated cardiomyopathy
C. The incidence of PPCM is greatest in first pregnancies
D. Approximately 10% of PPCM patients show recovery within the first 6 months after delivery
E. Younger maternal age is a risk factor for PPCM

QUESTION 637

A 67-year-old man with multivessel coronary disease is scheduled for coronary artery bypass graft surgery (CABG). Which of the following statements regarding CABG and perioperative complications is correct?

A. In-hospital mortality after isolated CABG has increased over the past 2 decades because of the increased complexity of patients who undergo the procedure
B. Early postoperative cognitive decline occurs in <10% of patients after CABG surgery
C. Atrial fibrillation appears in approximately 40% of patients after CABG surgery
D. Of patients who develop postoperative atrial fibrillation, only 20% will spontaneously revert to sinus rhythm within 24 hours
E. *N*-Acetylcysteine prevents renal dysfunction after CABG

QUESTION 638

The patient in Question 637 undergoes coronary artery bypass graft (CABG) surgery without complication. At his first postoperative office visit he reports resolution of his anginal symptoms and asks how long the benefit will last. Which of the following statements regarding CABG surgery is TRUE?

A. Fewer than 2% of saphenous vein grafts become occluded in the early perioperative period
B. Internal mammary artery grafts typically develop intimal hyperplasia over time
C. Saphenous vein grafts have a 10-year patency rate of >75%
D. Radial artery grafts are less likely to develop vasospasm than internal mammary grafts
E. Patients who receive internal mammary artery grafts suffer fewer late deaths and myocardial infarctions than those who receive only saphenous vein grafts

QUESTION 639

A previously healthy 17-year-old high school athlete collapses during a basketball game. He is noted to have brief seizure-like activity and has no initial pulse but is immediately resuscitated by a brisk precordial thump. Assuming that this event represents sudden cardiac death (SCD), which of the following statements is NOT correct?

A. Arrhythmogenic right ventricular cardiomyopathy is responsible for approximately 30% of SCD in young athletes
B. Anomalous origin of the left main coronary artery from the right coronary cusp is the most common of the congenital coronary abnormalities that result in SCD in young athletes
C. His normal pretraining history and physical examination do not exclude the possibility of hypertrophic cardiomyopathy (HCM)
D. Patients who experience SCD due to HCM often have no history of prior cardiac symptoms
E. Congenital aortic stenosis is a cause of SCD in young athletes

QUESTION 640

A 68-year-old woman with a history of hypertension presents to the emergency department with the new onset of dyspnea and nausea. The electrocardiogram shows anterolateral ST-segment depressions, and the initial serum measurement of cardiac troponin T is elevated. Which of the following statements is TRUE regarding women who present with acute coronary syndromes (ACS)?

A. Most women presenting with an acute myocardial infarction do not describe chest pain
B. Women presenting with myocardial infarction are less likely than men to have accompanying cardiovascular comorbidities
C. Women with ACS are more likely to present earlier in the course of symptoms than men
D. Women who present with chest discomfort are more likely than men to have nonatherosclerotic causes of ischemia, such as coronary vasospasm
E. Women are admitted to the hospital for the evaluation of chest pain less often than men

QUESTION 641

A 65-year-old man with end-stage renal disease, on stable hemodialysis, is diagnosed with atrial fibrillation. It is determined that he warrants anticoagulation for stroke prevention. Which of the following agents is labeled for use in patients on hemodialysis?

A. Rivaroxaban
B. Apixaban
C. Dabigatran
D. Edoxaban
E. None of the above

QUESTION 642

A 58-year-old postmenopausal woman presents for a routine office visit. She inquires about oral hormone replacement therapy recommended by her gynecologist. Which of the following statements is TRUE regarding the use of hormone replacement therapy and cardiovascular risk?

A. Current guidelines recommend hormone replacement therapy for postmenopausal women who do not have a history of coronary artery disease
B. The prospective Women's Health Initiative trial showed a reduced rate of coronary events in postmenopausal women randomized to estrogen-only treatment
C. The Women's Health Initiative showed no difference in the rate of stroke or pulmonary embolism in patients randomized to estrogen therapy
D. The American Heart Association guidelines assign a class III recommendation to starting or continuing estrogen plus progestin therapy for primary or secondary prevention of cardiovascular disease

QUESTION 643

A 55-year-old overweight man (body mass index = 31.0) with type 2 diabetes mellitus and atrial fibrillation is found to have three-vessel coronary disease at angiography and is scheduled for coronary artery bypass graft surgery in 1 week. Which of the following conditions is associated with increased perioperative mortality in this specific patient?

A. His age
B. Timing of surgery
C. Atrial fibrillation
D. Obesity

QUESTION 644

A 38-year-old woman presents at the 37th week of pregnancy because of severe substernal chest pain over the past 30 minutes. An electrocardiogram demonstrates 4-mm ST-segment elevations in leads V_1 to V_4. Which of the following statements is correct?

A. Coronary artery spasm is the most common cause of this finding during pregnancy
B. Coronary artery dissection is the most likely cause in the peripartum period
C. Pregnancy does not alter the risk of sustaining a myocardial infarction
D. Inferior wall myocardial infarction is more common than anterior wall myocardial infarction during pregnancy
E. Pregnancy is an absolute contraindication to angiography

QUESTION 645

An 83-year-old man with hypertension and diabetes underwent coronary artery bypass graft (CABG) surgery 14 hours ago on an emergency basis. Preoperative angiography revealed severe stenoses of the left main and right coronary arteries. During the operation, the left internal mammary artery was grafted to the native left anterior descending artery and saphenous vein grafts were anastomosed to the first obtuse marginal branch of the circumflex coronary artery and to the posterior descending artery. The surgeon consults you because he is concerned that the patient may have suffered a perioperative myocardial infarction (MI). Which of the following statements is NOT correct?

A. His age, the emergency nature of his procedure, and the presence of left main coronary artery disease put this patient at increased risk for perioperative MI
B. Chest pain is not a reliable sign of MI in the post-CABG patient
C. An elevation of cardiac-specific troponin T more than three times the 99% upper reference limit is diagnostic of MI in this setting
D. The finding of new Q waves on the electrocardiogram is a reliable sign of perioperative MI
E. Paradoxical motion of the interventricular septum on echocardiography is a common finding after cardiac surgical procedures and does not necessarily indicate MI

QUESTION 646

A 78-year-old man presents with chest pain and acute 2-mm ST-segment elevations in leads V_1 to V_3. Which of the following statements is true regarding the management of acute myocardial infarction (MI) in elderly patients?

A. Fibrin-specific fibrinolytic agents are not associated with heightened intracerebral bleeding rates in patients >75 years
B. Antiplatelet therapy with prasugrel leads to superior outcomes compared with clopidogrel in patients >75 years of age who undergo percutaneous intervention

C. Angiotensin-converting enzyme inhibitors have been shown to reduce fatal and nonfatal events after MI in elderly patients
D. Elderly patients are less likely than younger patients to benefit from beta blockade for secondary prevention

QUESTION 647

Which of the following preoperative clinical characteristics most strongly predicts an increased risk of perioperative cardiovascular complications in patients >40 years of age undergoing major noncardiac surgery?
A. Presence of an S_3 gallop
B. Active cigarette smoking
C. Serum creatinine = 1.5 mg/dL
D. Mitral stenosis with calculated valve area of 2.0 cm^2
E. Hypertension controlled on drug therapy

QUESTION 648

A 69-year-old woman presents for a routine office visit. She has a history of hypertension and her blood pressure today is 165/90 mm Hg. The only medication is metoprolol succinate 25 mg daily. Which of the following statements regarding hypertension in the elderly is TRUE?
A. Therapy for isolated systolic hypertension in the elderly does not reduce the incidence of future cardiac events
B. Clinical trials have shown that beta blockers offer less cardiovascular protection than diuretic therapy
C. The presence of left ventricular hypertrophy in hypertensive patients >65 years is not an independent risk factor for adverse cardiovascular outcomes
D. Hypertensive hypertrophic cardiomyopathy of the elderly is more common in men

QUESTION 649

Which of the following statements regarding hemodynamic changes during normal pregnancy is NOT correct?
A. Total blood volume increases
B. Cardiac output increases
C. Stroke volume increases
D. Systemic vascular resistance increases
E. Heart rate increases

QUESTION 650

Which of the following cancer therapies is NOT associated with the listed cardiotoxic side effect?
A. Trastuzumab: Systolic heart failure
B. Bevacizumab: Hypertension
C. Ipilimumab: Myocarditis
D. Anastrozole: Venous thromboembolism

QUESTION 651

A 60-year-old woman with a history of hypertension and diabetes mellitus is admitted to the hospital because of an acute severe headache, nausea, and vomiting. Physical examination demonstrates a blood pressure of 180/90 mm Hg, normal jugular venous pressure, bibasilar rales, no cardiac gallops or murmurs, and no focal neurologic signs. The troponin I is elevated at 0.62 ng/dL (normal: <0.10 ng/dL). Computed tomography of the brain demonstrates an acute subarachnoid hemorrhage. The patient's electrocardiogram is shown in Fig. 5.1. Which of the following statements is TRUE?
A. A ruptured coronary plaque with partially occlusive thrombus is likely present
B. QT interval prolongation is uncommon in this setting
C. All of the cardiac abnormalities can be attributed to autonomic dysfunction in the setting of acute brain injury
D. Beta blockers are not effective at controlling ventricular tachycardia and fibrillation in this situation
E. The magnitude of electrocardiographic abnormalities in such a patient correlates with a poor cardiovascular outcome

QUESTION 652

A 68-year-old man with a history of myocardial infarction is scheduled for elective hernia repair. Which of the following statements regarding perioperative medication use in coronary disease patients undergoing noncardiac surgery is TRUE?
A. Cardiac adverse event rates are reduced when high-dose beta blocker therapy is initiated immediately before surgery
B. Nitrates decrease intraoperative myocardial ischemia and reduce rates of adverse cardiac outcomes

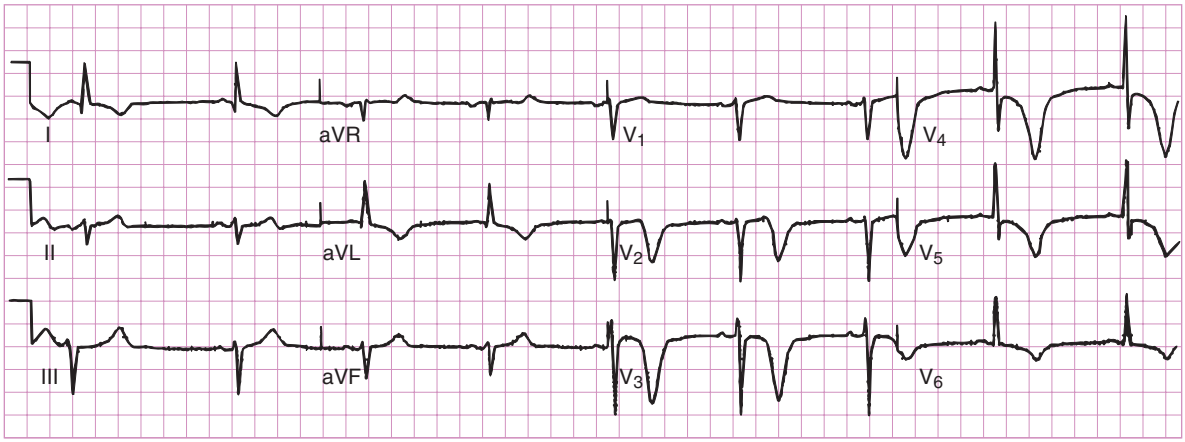

FIG. 5.1 *Courtesy Dr. Charles Fisch, Indiana University of Medicine, Indianapolis.*

C. Most cardiac medications should be discontinued 2 to 3 days before surgery and resumed as soon as the patient can tolerate oral intake
D. Statin therapy has been associated with reduced perioperative cardiovascular event rates in high-risk patients

QUESTION 653

Which of the following statements regarding alterations in cardiovascular function with aging is NOT correct?
A. Endothelial production of nitric oxide decreases with age
B. Left ventricular myocardial cells typically develop moderate hypertrophy
C. There is a fall in stroke volume due to a decrease in peak contractile force
D. Heart rate during exercise increases less in older, compared with younger, individuals
E. The resting ejection fraction tends to remain constant with age in the absence of cardiac disease

QUESTION 654

A 58-year-old diabetic man develops fever and tenderness at the sternal wound site 12 days after coronary artery bypass graft surgery. Which of the following has NOT been associated with the development of deep sternal wound infection after cardiac surgery?
A. Prolonged cardiopulmonary bypass time
B. Use of both internal mammary arteries as bypass vessels
C. Diabetes
D. History of cigarette smoking prior to surgery
E. Preoperative atrial fibrillation

QUESTION 655

A 27-year-old woman undergoes right-sided heart catheterization for the assessment of suspected pulmonary arterial hypertension. The mean pulmonary artery pressure (PAP) is 44 mm Hg, and the pulmonary capillary wedge pressure (PCWP) is 11 mm Hg. Infusion of epoprostenol reduces the mean PAP to 31 mm Hg with no significant change in systemic blood pressure or PCWP. Which of the following statements is NOT correct?
A. Both intravenous adenosine and inhaled nitric oxide are alternative useful agents to assess vasoreactivity
B. The observed drop in mean PAP is predictive of a favorable response to oral calcium channel blockers
C. The failure of the systemic blood pressure to decline suggests that the vasodilator challenge was ineffective
D. Very high doses of chronic calcium channel blocker therapy would likely be necessary to realize full clinical benefit
E. A rise in PCWP in response to vasodilator therapy would be of concern for impending left ventricular failure

QUESTION 656

Which of the following interventions has been shown to reduce the incidence of contrast-induced acute kidney injury after coronary angiography in patients with chronic renal insufficiency?
A. Infusion of 20% mannitol before angiography
B. Administration of atrial natriuretic peptide
C. Normal saline administration before and after angiography
D. Intravenous furosemide administration before angiography
E. Low-dose dopamine infusion

QUESTION 657

A 42-year-old woman presents to her primary care physician with recent fatigue and weight gain. Laboratory evaluation reveals a markedly elevated thyroid-stimulating hormone level. Which of the following is NOT a common cardiac finding in patients with hypothyroidism?
A. Hypotension
B. Decreased heart rate
C. Pericardial effusion
D. Decreased cardiac output
E. Prolonged QT interval on the electrocardiography

QUESTION 658

A 28-year-old woman with Marfan syndrome presents for an office visit. Her echocardiogram shows mitral valve prolapse, an aortic root diameter of 4.5 cm, and mild aortic regurgitation. Which of the following statements regarding cardiovascular disease in patients with Marfan syndrome is NOT correct?
A. Sixty percent to 80 percent of patients with Marfan syndrome have mitral valve prolapse on echocardiography
B. The development of aortic regurgitation correlates with the aortic root diameter
C. Patients with Marfan syndrome should be considered for elective aortic root replacement once the aortic root diameter exceeds 5.5 cm
D. Beta blockers should be administered to all patients with Marfan syndrome unless a contraindication exists
E. The risk of aortic dissection during pregnancy in patients with Marfan syndrome is increased if the diameter of the aortic root exceeds 4 cm

QUESTION 659

A 54-year-old man was admitted to the hospital because of acute pulmonary embolism. Intravenous administration of heparin was begun. On admission, the platelet count was 223,000/μL. Four days later it fell to 16,000/μL, although the patient remained asymptomatic, without overt bleeding. Which of the following statements regarding this patient's condition is TRUE?
A. Low-molecular-weight heparin can be safely substituted for intravenous unfractionated heparin
B. A direct thrombin inhibitor, such as lepirudin, should be substituted for heparin
C. Intravenous heparin should be continued, because the low platelet count represents a laboratory artifact without clinical significance
D. Antibodies directed against the platelet glycoprotein IIb/IIIa receptor participate in this disorder
E. This is a transient reaction to heparin and does not preclude future heparin treatment for this patient

QUESTION 660

A 51-year-old woman presents to discuss anticoagulation options for atrial fibrillation. Her history is notable for rheumatic mitral stenosis, which led to mitral valve replacement with a St. Jude mechanical prosthesis 6 years ago. She had

atrial fibrillation prior to cardiac surgery and it has persisted thereafter. She has been maintained successfully on warfarin anticoagulation, but she wishes to free herself of the required frequent testing of the prothrombin time and dose adjustments. She asks if one of the newer anticoagulants would be an option for her. She has normal renal function. Which of the agents below would be appropriate for this patient?
A. Rivaroxaban
B. Apixaban
C. Dabigatran
D. None of the above

QUESTION 661

Which of the following statements regarding metastatic disease involving the heart is TRUE?
A. Tumor metastases frequently involve the cardiac valves
B. A chylous pericardial effusion is characteristic of metastatic breast carcinoma
C. The most common cause of cardiac metastasis in men and women is lung cancer
D. A solitary cardiac mass is more likely to be malignant than benign

QUESTION 662

While volunteering at a medical clinic in rural India, you are asked to examine a 12-year-old girl who presents with fever, migratory polyarthritis, and an erythematous rash on her trunk that forms a snakelike ring with central clearing. Her cardiac examination is notable for a soft, high-pitched pansystolic murmur at the apex. She recalls a prolonged painful pharyngitis a few weeks ago. Two older family members are known to have mitral stenosis. In addition to the "major criteria" used for diagnosing this patient's likely condition, each of the following would offer supporting evidence EXCEPT
A. Prolonged QT interval
B. Fever
C. Elevated C-reactive protein
D. Arthralgia

QUESTION 663

A 42-year-old woman with rheumatoid arthritis (RA) presents with exertional dyspnea. Echocardiography demonstrates a small circumferential pericardial effusion without hemodynamic compromise. Which of the following statements regarding cardiovascular involvement in RA is TRUE?
A. Acute pericarditis related to RA occurs in 10% to 15% of patients
B. Patients with RA have a reduced incidence of clinical CAD compared to the general population
C. Conduction system disease in RA is most commonly due to inflammation of the conduction system.
D. Women with RA are twice as likely as age-matched controls to suffer myocardial infarction
E. At autopsy, epicardial coronary arteritis is found in >50% of patients with RA

QUESTION 664

A 76-year-old man with hypertension and diabetes is found to have atrial fibrillation for the first time at a routine office visit. He has no history of cardiac symptoms, and an echocardiogram shows normal left ventricular contractile function and no valvular disease or pericardial effusion. His physician initiates dabigatran etexilate for long-term anticoagulation. Which of the following statements is TRUE?
A. Anticoagulation for this patient is not warranted because his risk of thromboembolism is low
B. Dabigatran etexilate is an oral factor Xa inhibitor
C. The risk of stroke or systemic embolism with dabigatran 150 mg twice daily is lower than that with warfarin anticoagulation and a target international normalized ratio of 2.0 to 3.0
D. Dabigatran 150 mg twice daily is associated with a higher rate of hemorrhagic stroke than warfarin anticoagulation
E. Hepatotoxicity is the major gastrointestinal side effect of dabigatran

QUESTION 665

A 66-year-old man with a history of atrial fibrillation successfully suppressed by amiodarone presents with tremors and recent weight loss. His physician suspects amiodarone-induced thyroid dysfunction. Which of the following statements about amiodarone and thyroid function is NOT correct?
A. Amiodarone inhibits the peripheral conversion of thyroxine (T_4) to triiodothyronine (T_3)
B. During initial therapy, amiodarone decreases thyroid-stimulating hormone levels
C. Amiodarone contains 30% iodine by weight
D. Amiodarone's iodine content inhibits synthesis and release of T_4 from the thyroid gland
E. Glucocorticoid therapy is beneficial for patients with amiodarone-induced hyperthyroidism who have elevated circulating levels of interleukin-6

QUESTION 666

A 54-year-old man presents for evaluation of excessive daytime sleepiness. His wife has observed his prominent snoring and gasping at night. Which of the following statements regarding sleep-related breathing disorders and cardiovascular disease is NOT correct?
A. Individuals with obstructive sleep apnea exhibit persistently increased sympathetic activity, even during daytime wakefulness
B. Obstructive sleep apnea is associated with drug-resistant hypertension, automatic tachycardias, and nocturnal bradycardias
C. Positive airway pressure therapy in obstructive sleep apnea is associated with improved health-related quality-of-life, mood, and blood pressure
D. Unlike obstructive sleep apnea, central sleep apnea is not associated with cardiovascular disease
E. Positive airway pressure benefits both obstructive sleep apnea and central sleep apnea

QUESTION 667

A 38-year-old man with a recent history of unprovoked deep vein thrombosis presents to discuss long-term therapy for recurrent venous thromboembolism (VTE) prevention. He has just completed 6 months of warfarin anticoagulation without complication. Which of the following is NOT an evidenced-based regimen to reduce the risk of recurrent VTE?

A. Aspirin 100 mg daily
B. Warfarin 2 mg every other day
C. Apixaban 2.5 mg twice daily
D. Rivaroxaban 10 mg daily

QUESTION 668

Which of the following statements regarding perioperative cardiac risk assessment in patients undergoing noncardiac surgery is TRUE?
A. Preoperative serum creatinine concentration >1.5 mg/dL is an independent predictor of cardiac complications
B. Controlled insulin-dependent diabetes mellitus is a predictor of postoperative adverse cardiac outcomes
C. Transurethral prostate surgery is considered a high-risk procedure with respect to cardiac complications
D. In the current era, there is a 20% risk of reinfarction if surgery is performed 3 to 6 months after an acute MI
E. A history of exertional angina indicates high perioperative risk, even if the patient can carry a bag of groceries up one flight of stairs without stopping

QUESTION 669

A previously healthy 36-year-old woman presents to her primary care physician 3 weeks after the delivery of her second child because of new dyspnea, orthopnea, and peripheral edema. On examination, she appears fatigued. The blood pressure is 100/70 mm Hg and the heart rate is 120 beats/min. The jugular venous pressure is 12 cm H_2O. There are basilar rales, a prominent apical S_3 gallop, hepatomegaly, and bilateral lower extremity edema. An echocardiogram shows four-chamber cardiac enlargement and severe, global reduction of biventricular systolic function, compared with a normal study before pregnancy. Which of the following statements regarding this patient's condition is NOT correct?
A. The incidence of this disorder is greater with twin pregnancies
B. Approximately half of the patients with this disorder will completely recover normal cardiac function
C. Subsequent pregnancies are usually well tolerated
D. This condition becomes symptomatic in most patients during the last trimester of gestation or in the early postpartum period
E. The incidence of this disorder is higher among African American women than among whites

Directions:

Each group of questions below consists of lettered headings followed by a set of numbered questions. For each question, select the ONE lettered heading with which it is most closely associated. Each lettered heading may be used once, more than once, or not at all.

QUESTIONS 670 TO 674

For each description listed below, match the appropriate diagnosis:
A. Behçet syndrome
B. Systemic sclerosis
C. Ankylosing spondylitis
D. Reactive arthritis
E. Giant cell arteritis

670. Granuloma formation in the coronary arteries
671. Aortitis, uveitis, and urethritis
672. Myocardial fibrosis and contraction band necrosis
673. Histologically similar to syphilitic aortitis
674. Occlusion of the subclavian artery and aneurysms of the common carotid artery

QUESTIONS 675 TO 678

Match the cardiac medication with the potential adverse effect:
A. Heparin
B. Alpha-methyldopa
C. Procainamide
D. Ticagrelor

675. Erythematous rash, leukopenia
676. Coombs-positive hemolysis
677. Dyspnea
678. Thrombocytopenia

QUESTIONS 679 TO 683

Match the description with the associated disease:
A. Takayasu arteritis
B. Giant cell arteritis
C. Both
D. Neither

679. Occurrence is predominantly in women
680. Onset is typically during teenage years
681. Jaw muscle claudication suggests the diagnosis
682. Fever is almost always present
683. Steroid therapy is a cornerstone of management

QUESTIONS 684 TO 688

Match the chemotherapeutic agent with the likely cardiac complication:
A. Myocardial infarction
B. Acute myopericarditis
C. Capillary leak syndrome
D. Arrhythmias (acutely) and dilated cardiomyopathy (chronically)
E. Hypertension

684. Interleukin-2
685. 5-Fluorouracil
686. Cyclophosphamide
687. Doxorubicin
688. Sunitinib

QUESTIONS 689 TO 693

Match the cardiac finding with the most likely endocrine abnormality:
A. Hyperparathyroidism
B. Hypothyroidism
C. Hyperaldosteronism
D. Cushing syndrome
E. Hyperthyroidism

689. U waves on the electrocardiogram
690. Cardiac myxoma
691. Means-Lerman scratch
692. Shortened QT interval
693. Pericardial effusion

QUESTIONS 694 TO 697

Match the description to the associated fibrinolytic agent:
A. Streptokinase
B. Tissue-type plasminogen activator
C. Urokinase
D. Tenecteplase

694. Both single- and two-chain forms demonstrate proteolytic activity
695. Synthesized in renal tubular epithelial cells and endothelial cells
696. Prolonged half-life allows administration as a single bolus
697. Must form complex with plasminogen to exhibit enzymatic activity

QUESTIONS 698 TO 702

Match the finding to the associated anticoagulant:
A. Unfractionated heparin
B. Low-molecular-weight heparin
C. Both
D. Neither

698. Hyperkalemia
699. Bioavailability after subcutaneous injection is >90%
700. Inactivates clot-bound thrombin
701. Thrombocytopenia
702. Increases vascular permeability

QUESTIONS 703 TO 706

Match the following complications with the associated rheumatologic disorder:
A. Aortitis and headaches
B. Libman-Sacks endocarditis
C. Pulmonary hypertension
D. Aneurysmal dilatation of the subclavian and carotid arteries

703. Behçet syndrome
704. Systemic lupus erythematosus
705. Giant cell arteritis
706. Systemic sclerosis

Section V Answers

(CHAPTERS 88 TO 99)

Cardiovascular Disease in Special Populations; Cardiovascular Disease and Disorders of Other Organs

ANSWER TO QUESTION 630

C (Braunwald, pp. 1039–1040, 1042; Fig. 78.12; eTable 78.1)

In the United States, standard screening of young athletes typically consists only of history-taking and physical examination. This approach has a limited capability of detecting serious forms of cardiac disease that could lead to sudden cardiac death (SCD) during training, such as hypertrophic cardiomyopathy (HCM), anomalous origin of the coronary arteries, arrhythmogenic right ventricular cardiomyopathy, and inherited arrhythmia syndromes (e.g., long QT syndromes or Brugada syndrome). Patients with a family history of SCD or premature heart disease, and those with cardiac symptoms (including inordinate exertional dyspnea, chest pain, syncope, or near-syncope) or a heart murmur that augments with standing or Valsalva maneuver, warrant a more complete evaluation, usually including electrocardiography and echocardiography. This issue is particularly relevant since implantation of automatic defibrillators can prevent SCD in patients with predisposing conditions.

The most common cause of SCD in athletes in the United States is HCM. This diagnosis can be difficult to distinguish from the physiologic hypertrophy observed in individuals who participate in chronic endurance or isometric activities ("athlete's heart"), in whom left ventricular (LV) wall thicknesses of 13 to 15 mm can be observed (Fig. 5.2). Thus, voltage criteria for LV hypertrophy do not establish the diagnosis of hypertrophic or hypertensive cardiomyopathy in trained athletes. Echocardiographic findings more suggestive of *pathologic* hypertrophy include (1) LV wall thicknesses >15 mm, (2) prominent asymmetric LV hypertrophy, (3) LV end-diastolic cavity diameter <45 mm, (4) marked left atrial enlargement, (5) abnormal LV Doppler filling patterns, and (6) lack of regression of hypertrophy after a period of deconditioning. A distinguishing feature during cardiopulmonary exercise testing is that conditioned athletes with physiologic hypertrophy can achieve maximum oxygen uptakes >45 mL/kg/min (>110% predicted), whereas those with HCM typically cannot. Patients in whom cardiac assessment reveals HCM should be restricted from competitive athletics.

Anomalous origin of the coronary arteries is the second most common cause of SCD in athletes in the United States. Evaluation for this diagnosis includes coronary angiography or computed tomography angiography.

ANSWER TO QUESTION 631

D (Braunwald, pp. 1910, 1917–1918)

Chronic kidney disease (CKD) identifies a patient population at high risk for cardiovascular events. Up to 40% of patients with CKD who present to the hospital with chest pain have a cardiac event within 30 days. Moreover, patients with end-stage renal disease have the highest mortality after acute myocardial infarction of any large population with chronic disease. Contributors to poor outcomes after acute coronary syndromes in patients with CKD include (1) high prevalence of comorbidities such as diabetes mellitus and heart failure, (2) reduced use of effective therapeutics due to fear of worsening renal dysfunction, (3) therapeutic toxicities, and (4) vascular dysfunction that is exacerbated by renal failure, including a procoagulable and proinflammatory state. Whereas the latter contributes to increased rates of coronary thrombosis, uremia is also associated with impaired platelet aggregation, so patients with CKD can display increased bleeding risk at the same time.

TABLE 5.1 "Red Flags" for Takayasu Arteritis

In patients younger than 40 years, the following may be indicative of TA:
Unexplained acute-phase response (raised ESR and/or CRP)
Carotidynia
Hypertension
Discrepant blood pressure between the arms (>10 mm Hg)
Absent/weak peripheral pulse or pulses
Limb claudication
Arterial bruit
Angina

CRP, C-reactive protein; *ESR,* erythrocyte sedimentation rate; *TA,* Takayasu arteritis.

TABLE 5.2 Clinical Profile of Giant Cell Arteritis

ABNORMALITY	FREQUENCY (%)
Atypical headache	60–90
Tender temporal artery	40–70
Systemic symptoms not attributable to other diseases	20–50
Fever	20–50
Polymyalgia rheumatica	30–50
Acute visual abnormalities	12–40
Transient ischemic attack or stroke	5–10
Claudication	
Jaw	30–70
Extremity	5–15
Aortic aneurysm	15–20
Dramatic response to corticosteroid therapy	~100
Positive temporal artery biopsy	~50–80

Impact of chronic kidney disease on early (30-day) and late (1-year) outcomes of patients with acute coronary syndromes treated with alternative antithrombotic treatment strategies: an ACUITY (Acute Catheterization and Urgent Intervention Triage strategY) substudy. *JACC Cardiovasc Interv.* 2009;2:8.

ANSWER TO QUESTION 632

C (Braunwald, pp. 1850–1854, 1861; Table 94.3)

This patient has signs and symptoms of Takayasu arteritis (TA), an idiopathic large-vessel vasculitis that usually affects the aorta and its branches. TA is 10 times more likely to affect women than men, and the median age of onset is 25 years old. This disease occurs worldwide with a prevalence of 2.6 per million in the United States and 1.26 per million in northern Europe. Features that should prompt consideration of TA are listed in Table 5.1.

Clinically, arterial stenoses occur three to four times more often than aneurysms. Thus, claudication (more common in the upper than lower extremities) is the major symptom; on physical examination, bruits and asymmetric pulses are the most frequent findings. When aneurysms occur, the aortic root is the most common location, which can lead to aortic regurgitation. Hypertension is common and is often caused by renal artery stenosis. Coronary arterial vasculitis most often affects the ostia of the vessels, leading to myocardial ischemia. In addition, myocarditis occurs in about 18% of patients.

Treatment involves high-dose corticosteroids, but relapses are common. Patients with resistant or relapsing symptoms may respond to azathioprine, mycophenolate mofetil, methotrexate, leflunomide, or intravenous cyclophosphamide. More recently, anti-interleukin-6 therapy (i.e., tocilizumab) has been used successfully in some patients with TA that is refractory to conventional therapies. Anatomic bypass of clinically significant stenosis may be necessary. Involvement of the aortic root may necessitate aortic repair, with or without valve replacement.

ANSWER TO QUESTION 633

D (Braunwald, pp. 1850, 1853–1854)

This patient has characteristic features of giant cell arteritis (GCA), which typically includes the new onset of headache, scalp and temporal artery tenderness, polymyalgia rheumatica, acute visual abnormalities, and claudication of the jaw (Table 5.2).[1] Such symptoms, in the presence of an

increased erythrocyte sedimentation rate (ESR), support the diagnosis of GCA and mandate treatment, even without proof of diagnosis from a temporal artery biopsy. Corticosteroid treatment is the most effective therapy for GCA, and dramatic clinical improvement typically follows within 24 to 72 hours. The ESR itself does not always normalize with effective therapy, and it should not be relied on as the main measure of disease activity.

Most cytotoxic and other immunosuppressive agents, including anti-TNF agents, have not proved effective in GCA in controlled trials. However, a recent trial of tocilizumab (anti-interleukin-6 therapy) used in combination with corticosteroids resulted in a higher rate of sustained remission from GCA at 1 year as compared to corticosteroids alone.[2] Two retrospective studies have demonstrated that the use of low-dose aspirin reduces cerebral ischemic events three- to fourfold compared with patients who had not received such therapy. Therefore, most patients with GCA should receive low-dose daily aspirin.[3]

ANSWER TO QUESTION 634

D (Braunwald, p. 1791; Table 90.4)

Hypertension during pregnancy is associated with increased maternal mortality and morbidity and consists of four forms (Table 5.3): (1) chronic hypertension (hypertension that precedes pregnancy), (2) gestational hypertension (hypertension that develops after 20 weeks of gestation and resolves by the 12th postpartum week), (3) preeclampsia (de novo or superimposed on chronic hypertension), and (4) white coat hypertension. *Preeclampsia* is identified by the new onset of hypertension after the 20th week of gestation with proteinuria, maternal organ dysfunction, and/or uteroplacental insufficiency. It is more likely to occur in primigravid patients, in twin pregnancies, and in those with preexisting hypertension. Preeclampsia is an emergency and requires hospitalization for close maternal-fetal monitoring, control of hypertension, magnesium sulfate to prevent eclamptic seizures, and consideration of urgent delivery of the fetus, especially after 37 weeks' gestation, after which blood pressure usually normalizes rapidly. *Eclampsia* is present when findings of preeclampsia are accompanied by neurologic complications, including seizures.

Pharmacologic therapies that have been used successfully to lower blood pressure during pregnancy include methyldopa, beta blockers (particularly labetalol), calcium channel blockers, and hydralazine. Although these medications are effective in treating chronic hypertension that has worsened during pregnancy, they are not effective in preventing preeclampsia.

Angiotensin-converting enzyme inhibitors and angiotensin receptor blockers increase the risk of congenital malformations and neonatal renal failure and should *not* be used in pregnancy.

TABLE 5.3 Classification of Hypertension in Pregnancy

HYPERTENSION TYPE	DEFINITION/DESCRIPTION
Chronic hypertension	Hypertension (blood pressure ≥140 mm Hg systolic or ≥90 mm Hg diastolic) present before pregnancy or that is diagnosed before the 20th week of gestation
Gestational hypertension	• New hypertension with a blood pressure of 140/90 mm Hg on two separate occasions, without proteinuria, arising de novo after the 20th week of pregnancy • Blood pressure normalizes by 12 weeks postpartum
Preeclampsia superimposed on chronic hypertension	Increased blood pressure above the patient's baseline, a change in proteinuria, or evidence of end-organ dysfunction
Preeclampsia-eclampsia	• Proteinuria (protein excretion >0.3 g during 24 hours or grade ++ in two urine samples) in addition to new hypertension • Edema no longer included as diagnostic criterion because of poor specificity • In the absence of proteinuria, the disease should nevertheless be suspected when increased blood pressure is associated with headache, blurred vision, abdominal pain, low platelets, or abnormal liver enzymes

ANSWER TO QUESTION 635

B (Braunwald, pp. 1767, 1770)

Cardiovascular disease is the number one cause of mortality for women in the United States, accounting for 1 in 4 deaths. Fortunately, age-adjusted heart disease mortality has *declined* in both men and women in recent decades, attributed to beneficial risk factor modifications and the influence of evidence-based therapies in the treatment of coronary artery disease, acute coronary syndromes, and heart failure.[1]

Coronary heart disease first presents approximately 10 years later in women than in men, most commonly after menopause. The INTERHEART study demonstrated that this pattern is widely consistent across the world. The age difference is likely contributed to by a protective effect of circulating estrogen before menopause. Nonetheless, pharmacologic replacement of estrogen after menopause does not prevent clinical cardiovascular events.[2,3]

As in men, hyperlipidemia, hypertension, tobacco use, diabetes mellitus, obesity, and a sedentary lifestyle are all important modifiable risk factors for the development of heart disease in women. In the United States, nearly 36% of women have a low-density lipoprotein cholesterol level ≥130 mg/dL and more than 45 million women are hypertensive, a prevalence that exceeds that of men after age 60. There are >15 million women with diabetes mellitus, a population in which the rate of fatal coronary heart disease is higher than that of diabetic men.

ANSWER TO QUESTION 636

B (Braunwald, pp. 1589, 1790)

Peripartum cardiomyopathy (PPCM) is a form of dilated cardiomyopathy that occurs for the first time in the antepartum or postpartum period and is clinically indistinguishable from other types of dilated cardiomyopathy. PPCM is not a precisely defined entity, but general features include: (1) the development of heart failure (HF) in the last month of pregnancy or within 5 months of delivery, (2) reduced left ventricular ejection fraction (generally <45%), and (3) absence of previously known structural heart disease.[1,2] Recent studies have suggested significant overlap in the genetic predisposition to PPCM and other forms of idiopathic dilated cardiomyopathy.[3]

The incidence of PPCM varies by geographic region but is estimated to be between 1 in 1000 and 1 in 3200 live births. Risk factors for its occurrence include multiparity, African American race, older maternal age, and preeclampsia.

Approximately 50% of patients with PPCM show complete or near-complete left ventricular recovery on standard medical therapy. The other 50% demonstrate either continued deterioration or persistent left ventricular dysfunction and chronic HF symptomatology. Subsequent pregnancies in patients with PPCM with persistent cardiac dysfunction should be discouraged because of the high likelihood of relapse. Even patients who have recovered from an episode of PPCM have a 30% risk of experiencing relapse during subsequent pregnancies.[2]

ANSWER TO QUESTION 637

C (Braunwald, pp. 1242–1243)

The frequency of perioperative complications in coronary artery bypass graft surgery (CABG) has increased because of the greater percentage of high-risk patients who undergo the operation.[1,2] However, the in-hospital *mortality* after isolated CABG has actually declined, from ~3% in 1997–1999 to ~2% in 2015. The reported incidence of perioperative myocardial infarction varies widely, with a median of 2.9%.

Cerebrovascular complications can occur after cardiac surgery by mechanisms that include atherosclerotic cerebral emboli from the aorta, emboli related to the cardiopulmonary bypass machine, and intraoperative hypotension. Prospective studies reveal a post-cardiac surgical incidence of stroke ranging from 1.5% to 5.0%.[3] Short-term cognitive decline has been identified in >50% of patients at the time of hospital discharge.

Atrial fibrillation (AF) is one of the most frequent complications of bypass surgery, developing in approximately 40% of patients within 3 days after surgery. It is associated with a two- to threefold increase in postoperative stroke. Up to 80% of patients spontaneously revert to sinus rhythm within 24 hours without treatment other than rate control agents. Prophylactic use of beta blockers or amiodarone reduces the occurrence of postoperative AF.[4]

The incidence of renal failure requiring dialysis after CABG is low (0.5% to 1.0%) but is associated with greater morbidity and mortality when it occurs. Predictors of postoperative renal dysfunction include advanced age, diabetes, preexisting renal dysfunction, and heart failure. In a randomized trial, *N*-acetylcysteine did not prevent renal dysfunction after CABG.[5]

ANSWER TO QUESTION 638

E (Braunwald, pp. 1240–1241)

A variety of conduit options are available for coronary artery bypass graft surgery. Saphenous vein grafts are relatively easy to harvest, but they have several drawbacks. Approximately 8% to 12% of saphenous vein grafts become occluded during the early perioperative period. By 1 year, 15% to 30% of vein grafts occlude. Some of these occlusions may be due to endothelial denuding during surgical preparation, thereby predisposing the graft to early thrombosis. Intimal hyperplasia and accelerated atherosclerosis in vein grafts are common, and by 10 years after surgery, the patency rate of saphenous vein conduits is <50%.

In contrast, internal mammary artery (IMA) grafts, although more difficult to harvest, do not develop intimal hyperplasia and have 10-year patency rates of >80%. Several potential explanations for the superiority of IMA grafts have been suggested: (1) the medial layer of arterial grafts may derive additional nourishment from the vasa vasorum, (2) the endothelium of the IMA produces high levels of endogenous

vasodilators, and (3) the diameter of the IMA is closer to that of the recipient coronary artery than is the diameter of the saphenous vein. Compared to patients with saphenous vein grafts, patients who receive IMA conduits have a decreased risk of death, myocardial infarction, and reoperation. Other arterial conduits, such as the radial artery, are used less often. Although more likely to develop vasospasm than IMA grafts, radial artery grafts are also effective conduits with high long-term patency rates.

ANSWER TO QUESTION 639

A (Braunwald, pp. 822, 1039–1040; see also Answer to Question 630)

Sudden cardiac death (SCD) in young athletes is a rare, tragic event. The most common cause of SCD in the United States is hypertrophic cardiomyopathy (HCM). It is common for SCD victims with HCM to have been asymptomatic throughout their lives, and even routine history and physical examination before undertaking competitive sports will miss many cases.

The second most common etiology of SCD in young athletes is anomalous origin of a coronary artery. The most frequent form is anomalous origin of the left main coronary artery from the right coronary cusp. The opposite configuration, anomalous origin of the right coronary artery from the left aortic sinus, has also been identified as a cause of SCD. Myocardial ischemia in individuals with anomalous coronaries may relate to a kinked takeoff of the artery or compression of the vessel between the aorta and pulmonary trunk during exercise. Like HCM, coronary anomalies are very difficult to identify by routine screening.

Much less common causes of SCD in young athletes include atherosclerotic coronary disease, myocarditis, aortic dissection, congenital valvular aortic stenosis, and arrhythmogenic right ventricular cardiomyopathy.

ANSWER TO QUESTION 640

D (Braunwald, pp. 1770–1773)

Compared with men, women experiencing an acute coronary syndrome more frequently describe milder symptoms and are more likely to have "atypical" and often nonspecific symptoms, including dyspnea, pain or discomfort in other body locations, fatigue, indigestion, nausea, or generalized weakness. Despite sex differences in symptom perception of myocardial ischemia, however, the majority of women with acute myocardial infarctions report chest pain.[1] In addition, women presenting with myocardial infarctions typically have more comorbidities (e.g., hypertension) than men, and often present later in the course of symptoms and more frequently with high-risk clinical findings such as heart failure.[2]

Women are hospitalized more frequently than men each year for the evaluation of chest pain, but women who present with chest discomfort are more likely than men to have a nonatherosclerotic cause of ischemia, including coronary vasospasm, stress "takotsubo" cardiomyopathy, and spontaneous coronary artery dissection.

ANSWER TO QUESTION 641

B (Braunwald, pp. 1841–1843; Table 93.10; see also Answer to Question 74)

The direct thrombin inhibitor dabigatran, and the factor Xa inhibitors rivaroxaban, apixaban, and edoxaban, are non–vitamin K antagonist oral anticoagulants (NOACs) approved by the US Food and Drug Administration (FDA) for the prevention of stroke in patients with nonvalvular atrial fibrillation (AF), and the treatment of deep venous thrombosis and pulmonary embolism. Each of these agents is in part cleared through renal excretion, and the doses of all four agents must be lowered in patients with reduced creatinine clearance (CCr). Additionally, rivaroxaban, edoxaban, and dabigatran should not be prescribed at all for patients with CCr <15 mL/min.[1]

Apixaban has the lowest proportion of renal excretion (25%) among the available NOACs. Its FDA-approved labeling recommends reduced dosage (2.5 mg twice daily, instead of 5 mg twice daily) for patients with AF and serum creatinine >1.5 mg/dL, *if* the patient also weighs ≤60 kg, or if age is ≥80 years. Apixaban is also approved for use in hemodialysis (5 mg twice daily, or 2.5 mg twice daily for age ≥80 years or body weight ≤60 kg) based on a small pharmacokinetic study.[2] In a retrospective review that compared apixaban with warfarin in patients with severe renal impairment, these anticoagulants resulted in similar bleeding and thrombotic complications.[3] Nonetheless, for patients with end-stage renal disease, and for those on dialysis, there is a long track record of acceptable safety with warfarin, which currently remains the anticoagulant of choice in these conditions.

ANSWER TO QUESTION 642

D (Braunwald, p. 1770)

Past observational studies had suggested a benefit of postmenopausal hormone replacement therapy in primary and secondary prevention of coronary artery disease events. However, more recent large randomized prospective trials have shown that hormone replacement therapy fails to reduce coronary events. In the Women's Health Initiative estrogen-only trial, 10,739 postmenopausal women were randomized to placebo or 0.625 mg of oral conjugated equine estrogens daily. The trial was stopped early because there was no significant benefit of estrogen on the primary composite endpoint of death or nonfatal myocardial infarction, but the risk of stroke and pulmonary embolism *increased* in the estrogen arm of the study. Current American Heart Association guidelines assign a class III recommendation to the use of estrogen plus progestin for primary and secondary prevention (i.e., risk is greater than benefit and should not be used).

ANSWER TO QUESTION 643

C (Braunwald, pp. 1242–1243)

Factors that significantly increase mortality with coronary artery bypass graft surgery (CABG) include increasing age, urgent or emergent surgery, prior cardiac surgery, serum creatinine >2 mg/dL, female gender, left ventricular dysfunction, peripheral arterial disease, severe neurologic disease, and chronic obstructive lung disease. Scoring systems including the Society of Thoracic Surgeons risk estimator and the European System for Cardiac Operative Risk Evaluation (EuroSCORE) can be used to assess the risk of adverse outcomes in individual patients.[1,2] Obesity has not been shown to be an independent predictor of mortality or cerebrovascular accidents after CABG; however, it does predict risk of developing of postoperative mediastinitis. Although not included in the EuroSCORE, preoperative atrial fibrillation is also associated with increased perioperative mortality and morbidity in patients undergoing cardiac surgery.[3]

ANSWER TO QUESTION 644

B (Braunwald, p. 1790)

Acute myocardial infarction (AMI) is rare in women of childbearing age, but pregnancy increases the risk three- to fourfold. AMI can occur during any stage of pregnancy and is more frequent in multigravida women. Most events occur in women >30 years and the majority of the time the location is the anterior wall. Although atherosclerotic disease is typically uncommon in young women, there is a relatively high incidence of traditional risk factors among those who experience AMI during pregnancy, including cigarette smoking, hyperlipidemia, hypertension, and diabetes. The most common findings at coronary angiography in pregnant women with AMI are atherosclerotic disease (with or without intracoronary thrombus) or coronary artery dissection, the latter being the most common cause of AMI in the peripartum period. Coronary spasm or embolism is much rarer. Even during pregnancy, acute management of ST-segment elevation AMI warrants urgent coronary angiography, with percutaneous coronary intervention and stenting if appropriate. The safety of drug-eluting stents and their required prolonged dual antiplatelet therapy is unknown in pregnancy, and most experience to date has been with bare metal stents.

ANSWER TO QUESTION 645

C (Braunwald, p. 1243)

Perioperative myocardial infarction (MI) has a major adverse effect on early and late prognosis following coronary artery bypass grafting (CABG).[1] The reported incidence of this complication is variable (0% to >10%) because of heterogeneous diagnostic criteria, with a median of 2.9%. The diagnosis of MI immediately after CABG can be difficult because usual criteria are not often applicable. For example, symptoms are not reliable because most patients are sedated and may not sense ischemic pain. Conversely, any chest discomfort described by the patient may be difficult to distinguish from sternal or pericardial sensations. The electrocardiogram may not be diagnostic because ST-segment abnormalities are very common after CABG. If new ST-segment *elevations* are observed, however, there should be concern for acute graft failure or spasm, which must be differentiated from the common diffuse ST-segment elevations representative of postoperative pericardial inflammation. The most reliable electrocardiographic findings of a post-CABG MI are new and persistent Q waves. Echocardiography may aid in the diagnosis of postoperative MI, as new wall motion abnormalities support the diagnosis of myocardial injury. However, abnormal septal motion is not specific because most patients who undergo cardiac surgery have paradoxical septal movement for at least several months after cardiac surgery. Serum markers of myocardial necrosis are also difficult to interpret in the post-CABG setting. Total creatine kinase elevations are almost universally observed because of damage to skeletal muscle in the chest wall. Myocardial-specific creatine kinase-MB isoenzymes and cardiac troponins are frequently detected in the serum as a result of myocardial incisions made for cardiopulmonary bypass. As a result, the third Universal Definition of Myocardial Infarction defines MI after CABG as an elevation of cardiac biomarker values to more than 10 times the 99th percentile upper reference limit (in patients with normal baseline troponin values) in the presence of

other clinical findings supportive of myocardial infarction, including (1) new pathologic Q waves or new left bundle branch block, (2) angiographic evidence of new coronary or bypass graft occlusion, and/or (3) imaging evidence of new infarcted territory.[2]

Clinical risk factors for peri-CABG MI include older age, longer pump time, elevated left ventricular end-diastolic pressure, preoperative unstable angina, and significant left main coronary artery disease.

ANSWER TO QUESTION 646

C (Braunwald, pp. 1745–1746)

Older patients (>65 years of age) comprise 60% of hospital admissions for acute myocardial infarction (MI). According to a review of Medicare beneficiaries, elderly patients who present with an acute MI are more likely to have comorbid illnesses and exhibit higher rates of congestive heart failure, ventricular rupture, and mortality compared with younger individuals. Like younger age groups, there is a significant survival benefit from reperfusion therapies (percutaneous coronary intervention [PCI] or fibrinolysis) in acute ST-segment elevation MI in older patients, although few individuals >75 years have been included in pertinent clinical trials. For individuals up to the age of 75 years, most trials show that fibrinolytic, antiplatelet, and anticoagulant therapies are associated with a survival advantage; however, bleeding and transfusion rates are higher in older patients. Even fibrin-specific fibrinolytic agents are associated with increased stroke risk due to intracerebral hemorrhage in those >75 years. In patients >75 years who undergo PCI, antiplatelet therapy with prasugrel is associated with an increased risk of fatal bleeding events compared with clopidogrel and should be avoided in that population.

Ventricular remodeling after infarction may differ in the elderly because of alterations in the inflammatory response, decreased ability of the myocardium to hypertrophy, and increased collagen content of cardiac tissue. However, elderly patients benefit as much as younger individuals from beta blocker therapy for secondary prevention. In addition, in patients >65 years of age who have sustained an MI with residual left ventricular ejection fraction <40%, angiotensin-converting enzyme inhibitors reduce fatal and nonfatal events just as they do for younger individuals.

ANSWER TO QUESTION 647

A (Braunwald, pp. 102–103, 108)

Many patients >40 years old are likely to have coronary artery disease or other cardiac conditions that may influence the safety of noncardiac surgery. The Revised Cardiac Risk Index (RCRI) is one tool used to estimate the risk of perioperative cardiovascular complications. The RCRI includes the following six independent predictors of increased risk: high-risk type of surgery, history of ischemic heart disease, history of congestive heart failure (e.g., the S_3 gallop described in the vignette), history of cerebrovascular disease, preoperative treatment with insulin, and a preoperative serum creatinine >2 mg/dL. The more variables present, the greater the risk of a perioperative cardiovascular complication.

Notably, statistically nonsignificant risk factors include smoking, hyperlipidemia, and mild to moderate hypertension. And while preoperative unstable symptoms of angina portend a complicated postoperative course, such is not the case for patients with stable class I to II angina or remote MI without active angina. A history of supraventricular arrhythmias such as atrial fibrillation should alert the clinician to the possible development of similar rhythm disturbances postoperatively. Nonsustained ventricular tachycardia has not been associated with poor postoperative outcomes.

ANSWER TO QUESTION 648

B (Braunwald, pp. 1757–1758)

Data from several major randomized placebo-controlled trials indicate that therapy for systolic and/or diastolic hypertension in elderly patients reduces cardiovascular events. For example, in the landmark Hypertension in the Very Elderly trial, treatment of systolic hypertension reduced the incidence of both stroke and all-cause mortality. The 8th Joint National Committee on Prevention, Evaluation, and Treatment of Hypertension (JNC 8) had recommended a goal blood pressure of <150/90 in adults age 60 years or more.[1] More recently, however, the 2017 Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults revised the target to a blood pressure <130/80 for all adults, with the caveat that clinical judgment, patient preference, and a team-based approach to assess risks and benefits be applied for older adults (≥65 years old).[2]

Several studies, including the ALLHAT trial, have demonstrated that thiazide diuretics are efficacious and

a preferred first-line antihypertensive agent in the elderly. In large clinical trials, beta blockers have resulted in less cardiovascular protection than diuretics as first-line therapy. Other first-line agents include calcium channel blockers, angiotensin-converting enzyme inhibitors, and angiotensin receptor blockers.

Data from the Framingham Study have confirmed the importance of left ventricular hypertrophy as an independent risk factor for adverse cardiac outcomes in older, hypertensive subjects. Hypertensive hypertrophic cardiomyopathy in the elderly tends to be more common in women, and the presenting symptom is usually dyspnea.

ANSWER TO QUESTION 649

D (Braunwald, p. 1780; Fig. 90.2)

Several hemodynamic alterations occur during normal pregnancy (Fig. 5.3). Blood volume increases substantially, beginning during the second month, then rising to an average volume expansion of 50% by late pregnancy. The increase in blood volume occurs more quickly than an increase in hemoglobin, so anemia is common. The increased blood volume augments ventricular preload and stroke volume. The heart rate also rises steadily, usually by 10 to 20 beats/min by the third trimester. The augmented heart rate and stroke volume lead to a rise in cardiac output throughout pregnancy. Systemic vascular resistance begins to fall during the first trimester, reaches its lowest level in mid-pregnancy, then returns to the pre-pregnancy level before delivery. The drop in systemic vascular resistance likely reflects a combination of circulating gestational hormones, vasodilating prostaglandins, atrial natriuretic peptides, and nitric oxide, as well as the low-resistance circulation of the gravid uterus.

ANSWER TO QUESTION 650

D (Braunwald, pp. 1644–1646; Table 81.1)

Trastuzumab is a humanized monoclonal antibody that targets a subdomain of the human epidermal growth factor receptor 2 (HER2), termed ErbB2. It is predominantly used to treat HER2-positive metastatic breast cancer, but may also be effective in non-small cell lung cancer, gastric cancer, and esophageal cancer. The main potential cardiotoxicity of trastuzumab is cardiomyopathy, which may lead to severe clinical heart failure (HF). The risk of cardiomyopathy and HF is greatest in the setting of prior or concomitant anthracycline exposure. In many cases, the cardiomyopathy is partially or completely reversible with avoidance of trastuzumab and initiation of neurohormonal blockade.

Bevacizumab is a humanized recombinant monoclonal antibody that targets the vascular endothelial growth factor (VEGF) signaling pathway and has activity against a broad range of solid tumors. VEGF inhibitors may cause substantial systemic arterial hypertension through mechanisms that are incompletely understood. Less common cardiovascular complications of VEGF inhibitors include heart failure and arterial thromboembolic events.

Ipilimumab is an immune checkpoint inhibitor that targets cytotoxic T-lymphocyte-associated antigen 4 (CTLA-4). Checkpoint proteins like CTLA-4 are important negative regulators of T-cell activation, and inhibiting their function results in antineoplastic activity by preventing tumors from evading the immune system. Because checkpoint inhibitors do not selectively enhance the anti-tumor immune response, they can also cause widespread adverse inflammatory reactions. Although the risk is low, these agents have been associated with clinically significant and in some cases lethal myocarditis.

Anastrozole is an aromatase inhibitor, which blocks the conversion of androgens to estrogen and is a highly effective therapy in the treatment of hormone-receptor positive breast cancer. In contrast to the selective estrogen receptor modulator tamoxifen, aromatase inhibitors are *not* associated with an increased risk of venous thromboembolism. They are, however, associated with increased total cholesterol and hypertension.

ANSWER TO QUESTION 651

C (Braunwald, pp. 1906–1907)

This patient presents with an acute subarachnoid hemorrhage and a markedly abnormal electrocardiogram.

Electrocardiographic abnormalities are present in approximately 70% of patients with subarachnoid hemorrhage and can include ST-segment elevation or depression, deep symmetric T wave inversions as in this patient, and a prolonged QT interval that can lead to torsades de pointes. The mechanism of cardiac and electrocardiographic abnormalities in acute brain injury likely relates to autonomic nervous system dysfunction and excessive myocardial catecholamine release. In this setting, myocardial damage can occur with release of cardiac biomarkers, without primary acute coronary plaque rupture or thrombus formation. The magnitude of peak troponin elevation, but not the degree of electrocardiographic abnormality, is predictive of an adverse cardiac outcome. Beta blockers appear useful in minimizing myocardial damage and controlling arrhythmias in patients with subarachnoid hemorrhage.

ANSWER TO QUESTION 652

D (Braunwald, p. 114)

It is generally safe and appropriate to continue most chronically administered cardiac medications up to the day of surgery and to resume them as soon as possible after the operation. This is true of beta blockers in patients with underlying coronary artery disease (or other indications for chronic beta blocker use) and continuing such therapy perioperatively is a class I American College of Cardiology/American Heart Association guideline recommendation.[1] However, there has been controversy about the role of *initiating* preoperative beta blocker therapy for the purpose of risk reduction.[2] Conclusions from randomized clinical trials have varied, in part related to methodologic differences in the studies. The evidence to date suggests that beta blockers reduce the perioperative risk of cardiovascular events (ischemia, atrial fibrillation, need for coronary interventions), but can be associated with bradycardia, hypotension, and stroke, particularly if high doses or long-acting preparations are initiated shortly before surgery.[3] If initiation of preoperative beta blocker therapy is planned, it should be started at least 2 to 7 days before surgery to assess tolerability and safety and to allow titration of the dosage if appropriate. Thus, current guidelines recommend against initiation of a beta blocker without dose titration immediately before surgery (especially high-dose or long-acting forms).[1]

Although nitrates reduce intraoperative ischemia, cardiac outcomes are not affected.

Statins have anti-inflammatory and plaque-stabilizing properties, and studies in patients undergoing vascular surgery have demonstrated reduced cardiac event rates in patients on statin therapy perioperatively.[4]

ANSWER TO QUESTION 653

C (Braunwald, pp. 1735–1739)

Assessment of the heart's normal aging process is difficult because of the high prevalence of cardiovascular disease in older individuals. Studies in which coronary artery disease and other common cardiovascular conditions have been carefully excluded have revealed several pertinent findings. First, there is moderate hypertrophy of left ventricular myocardial cells, probably in response to increased arterial stiffness and loss of cardiac myocyte number with age. Although myocardial cells are unable to proliferate, they can increase in size as an adaptive response. Despite alterations in contractile proteins leading to reductions in the velocity of contraction and lengthening of contraction and relaxation times, peak contractile force production is maintained at normal levels, and there appear to be no changes in cardiac output, stroke volume, or ejection fraction at rest with normal aging. However, there are changes in beta-adrenoceptor-mediated inotropic and chronotropic cardiovascular responses with aging that result from generalized desensitization. Thus, the maximal heart rate during exercise and other cardiovascular responses to exercises are blunted.

Among the cellular and molecular changes that occur with aging, endothelial production of nitric oxide (NO) decreases, likely reflecting a combination of decreased endothelial cell mass (due to cell senescence and apoptosis) and increased NO utilization because of elevated vascular superoxide anion production in older subjects.

ANSWER TO QUESTION 654

D (Braunwald, pp. 1242–1243)

Deep sternal wound infection is among the most serious complications of cardiac surgery. Patients with deep sternal wound infections present approximately 2 weeks after surgery with fever, leukocytosis, bacteremia, discharge, and erythema at the wound site. Risk factors for the development of

mediastinal infection include a prolonged cardiopulmonary bypass time, excessive bleeding necessitating reexploration for hemostatic control, the use of both internal mammary arteries, and older age. Atrial fibrillation is also a predictor of mediastinitis in patients undergoing coronary artery bypass grafting. Obesity is the most important risk factor for sternal dehiscence, whether or not infection is present.[1]

The incidence of postoperative deep sternal wound infection appears to be decreasing.[2] A significant contribution to this reduction is that the rate among diabetics has fallen from about 3.2% to about 1.0% over the past decade, possibly related to the introduction of perioperative intravenous insulin.

About half of deep sternal wound infections are caused by *Staphylococcus* species, and gram-negative organisms account for about 40%. Confirmation of a sternal wound infection often requires surgical exploration and removal of material for Gram stain and culture. Imaging techniques, including computed tomography or magnetic resonance imaging, are helpful. Intravenous antibiotics, with possible debridement and irrigation, may be required for prolonged periods. Early diagnosis and initiation of treatment enhance the prognosis. Mediastinal infections have not been shown to change patency rates of bypass grafts.

ANSWER TO QUESTION 655

C (Braunwald, p. 1706)

Cardiac catheterization plays an important role in patients with suspected pulmonary arterial hypertension (PAH) to confirm the diagnosis, establish the severity of disease, and determine prognosis. Patients with PAH demonstrate a normal or low pulmonary capillary wedge pressure (PCWP), distinguishing PAH from pulmonary venous hypertension. A vasodilator challenge during catheterization allows assessment of pulmonary vasoreactivity and helps to guide therapy. Such a challenge can be accomplished with intravenous adenosine, intravenous epoprostenol, or inhaled nitric oxide. A favorable acute effect of these vasodilators (i.e., >10 mm Hg decrease in mean pulmonary artery pressure [PAP] to an absolute mean PAP lower than 40 mm Hg) without adverse effects (e.g., a decline in cardiac output or systemic blood pressure, or a rise in PCWP) is predictive of a favorable response to oral calcium channel blockers. An increase in PCWP during vasodilator testing would be consistent with pulmonary veno-occlusive disease or impending left ventricular failure.

When oral calcium channel blockers are used to treat PAH, high doses are required to achieve full clinical benefit.

ANSWER TO QUESTION 656

C (Braunwald, pp. 1913–1914; Fig. 98.5)

Risk factors for contrast-induced acute kidney injury (CI-AKI) include chronic renal insufficiency, diabetic nephropathy, intravascular volume depletion, renal artery stenosis, and concurrent use of agents that alter renal hemodynamics (e.g., angiotensin-converting enzyme inhibitors). The smallest possible volume of contrast agent should be used in patients with renal insufficiency, because the risk of nephrotoxicity is related to the amount injected.

At present, the intervention that has been demonstrated to consistently reduce the incidence of this complication in patients at risk is intravenous (IV) normal saline hydration before and after the procedure. A randomized trial of IV isotonic sodium bicarbonate in elective coronary procedures showed no difference in post-procedure CI-AKI compared with IV saline, such that either could be used for hydration. Several other agents have been evaluated for prevention of CI-AKI, including mannitol, calcium channel antagonists, dopamine, and atrial natriuretic peptide; however, none has been shown to reduce the risk of renal complications.[1]

It has been hypothesized that lower ionic strength contrast agents should reduce the incidence of contrast nephropathy. Although that has not been demonstrated in patients with normal baseline renal function, the risk of contrast-induced nephropathy *is* reduced in patients with baseline renal insufficiency (with or without diabetes) if nonionic low-osmolar contrast medium is used.

Small studies had suggested that oral administration of *N*-acetylcysteine, an antioxidant, could reduce the risk of CI-AKI; however, several large randomized trials did not confirm this benefit.[2,3]

ANSWER TO QUESTION 657

A (Braunwald, pp. 1817–1818)

The major cardiovascular changes that occur in hypothyroidism include a reduction in cardiac contractility, an increase in systemic vascular resistance, and a slowing of the heart rate. The decreased cardiac contractility and relative bradycardia result in a lower cardiac output. Thyroid hormone normally reduces smooth muscle tone, resulting in a decrease in peripheral vascular resistance. In the

relative absence of thyroid hormone, peripheral vascular tone increases and contributes to *hypertension*, which is common in hypothyroid patients. Thyroid hormone deficiency results in alterations in myocardial depolarization that can prolong the QT interval. Hypothyroidism is also associated with increased vascular permeability. Thus, pericardial effusions are common, developing in approximately one-third of patients, although progression to cardiac tamponade is rare.

ANSWER TO QUESTION 658

C (Braunwald, pp. 1300, 1307; see also Answer to Question 67)

Marfan syndrome, caused by mutations in the fibrillin gene (*FBN1*), is associated with significant morbidity and mortality from cardiovascular causes. The most life-threatening complication is aortic dissection, to which patients with Marfan syndrome are predisposed because of aortic cystic medial degeneration. Such dissections usually commence just above the coronary ostia and may extend into the entire length of the aorta. Beta blockers limit aortic shear stress and are an important component of prevention. Prospective studies have confirmed a slowing of aortic dilatation and reduced risk of dissection in patients treated with beta-blockers. Limited data suggest that therapy with an angiotensin receptor blocker may also slow progression of aortic enlargement, presumably through effects on transforming growth factor beta signaling.

The dimension of the proximal aorta can be followed serially by transthoracic echocardiography, computed tomography, or magnetic resonance imaging. Prophylactic aortic root replacement is recommended in Marfan syndrome patients once the diameter approaches 5 cm to prevent dissection and progressive aortic regurgitation.[1,2] Some groups recommend replacement even earlier, when the diameter is in the 4.5- to 5.0-cm range.

Aortic dissection is an unfortunate potential complication of pregnancy in Marfan syndrome, occurring most commonly between the third trimester and the first month postpartum. The risk of dissection in this setting is related to the size of the aortic root and appears to be low in patients with root diameters of ≤4 cm.[3]

Progressive valvular impairments are also common in patients with Marfan syndrome. The risk of severe aortic regurgitation increases as the diameter of the aortic root enlarges. Mitral valve prolapse, associated with elongated and redundant leaflets, is detected in 60% to 80% of patients by echocardiography.[4] Progression to severe mitral regurgitation occurs in up to 25% of patients.

ANSWER TO QUESTION 659

B (Braunwald, p. 1837; Tables 93.5 and 93.6)

This patient has heparin-induced thrombocytopenia (HIT), of which there are two forms. Type I HIT is the common, milder form that likely results from non–immune-mediated heparin-induced aggregation of platelets. Platelet counts usually drop within 2 days of therapy but rarely fall below 100,000/μL, and patients do not often develop bleeding complications. In the majority of such cases, heparin can be continued and the platelet count will improve.

Type II HIT, which has developed in the patient presented in this question, is the more dangerous form. It produces more severe thrombocytopenia, with levels often <50,000/μL. It develops when antibodies form against the heparin-platelet factor 4 (PF4) complex. These antibodies bind simultaneously to the heparin-PF4 complex and to platelet Fc receptors, an action that stimulates platelet activation and thrombosis. The diagnosis can be confirmed by the measurement of anti-heparin/PF4 antibodies.

Type II HIT usually becomes manifest for the first time within 4 to 14 days of the initiation of heparin therapy. However, on subsequent exposure, it can present quickly after even small doses of heparin. Therefore, patients with a history of type II HIT should never receive any form of heparin.[1]

When type II HIT develops, heparin should be stopped immediately (Table 5.4). If further anticoagulation is needed, a parenteral direct thrombin inhibitor, such as lepirudin, argatroban, or bivalirudin, can be substituted.[2] Fondaparinux, a synthetic pentasaccharide with anti-factor Xa activity, is another anticoagulant that can be used safely in patients with HIT.[3]

TABLE 5.4 Management of Heparin-Induced Thrombocytopenia

Stop all heparin.
Give an alternative anticoagulant, such as lepirudin, argatroban, bivalirudin, or fondaparinux.
Do not give platelet transfusions.
Do not give warfarin until the platelet count returns to baseline levels; if warfarin was administered, give vitamin K to restore the international normalized ratio to normal.
Evaluate for thrombosis, particularly deep vein thrombosis.

Low-molecular-weight heparins (LMWHs) are associated with a lower incidence of HIT than is intravenous unfractionated heparin (UFH). However, antibodies to UFH cross-react with LMWHs, so once a diagnosis of type II HIT is made, both types of heparin should be avoided.

ANSWER TO QUESTION 660

D (Braunwald, pp. 1458, 1839–1843)

The non–vitamin K antagonist oral anticoagulants are approved for use in nonvalvular atrial fibrillation, among other indications. However, none of these agents is approved for use in patients with mechanical heart valves. Dabigatran was compared to warfarin in the randomized, prospective RE-ALIGN trial of patients with bileaflet mechanical heart valves. The trial was terminated early because dabigatran was associated with increased rates of thromboembolic and bleeding complications compared with warfarin.

ANSWER TO QUESTION 661

C (Braunwald, pp. 1873–1874)

Metastatic tumors to the heart or pericardium are much more common than are primary cardiac malignancies. Metastases within cardiac structures are present at autopsy in approximately 9.1% of patients with malignant disease, whereas primary cardiac tumors are found in fewer than 0.1% of individuals postmortem. The most common malignancy that metastasizes to the heart is carcinoma of the lung (36% to 39% of metastases), followed in frequency by carcinoma of the breast and hematologic malignancies. Single metastases to the heart are rare, such that the finding of a solitary cardiac tumor is more likely indicative of a benign process.

Cardiac metastases typically involve the pericardium and myocardium, while the valves and endocardium are only rarely affected. Many cardiac metastases are clinically silent. For example, in malignant melanoma, 28% to 56% of patients have metastases to the myocardium or pericardium, yet cardiac symptoms are rare. The most common clinical manifestations of metastatic disease are due to pericardial effusion (i.e., tamponade), tachyarrhythmias, conduction blocks, and congestive heart failure.

A chylous pericardial effusion is characteristic of lymphoma.

ANSWER TO QUESTION 662

A (Braunwald, pp. 1514–1515; Table 74.2)

This patient presents with acute rheumatic fever (ARF) after probable streptococcal pharyngitis. ARF typically manifests as a subset of five major manifestations (the "Jones criteria"): carditis, polyarthritis, chorea, subcutaneous nodules, and erythema marginatum. In addition, several other symptoms and laboratory findings are usually present in this condition and constitute minor criteria. These include nonspecific arthralgias, especially of large joints, fever, elevated acute-phase reactants (i.e., erythrocyte sedimentation rate and C-reactive protein), and electrocardiographic findings that include prolongation of the PR interval (not the QT interval). The diagnosis of ARF is made in the presence of preceding group A beta-hemolytic streptococcal infection when two major criteria, or one major and two minor criteria are present.

In 2015, the Jones criteria were revised to recognize that their clinical utility is determined by the background disease prevalence of acute rheumatic fever in a given population (i.e., the pretest probability). As such, different thresholds are required for meeting the major and minor criteria in low-risk versus moderate- and high-risk populations (Table 5.5).[1]

REFERENCE

1. Gewitz MH, Baltimore RS, Tani LY, et al. Revision of the Jones criteria for the diagnosis of acute rheumatic fever in the era of Doppler echocardiography: a scientific statement from the American Heart Association. *Circulation.* 2015;131:1806–1818.

TABLE 5.5 2015 Jones Criteria for the Diagnosis of Rheumatic Fever[a]

LOW-RISK POPULATIONS	MODERATE- AND HIGH-RISK POPULATIONS
Major Criteria	
Carditis (clinical or subclinical[b]) Arthritis (polyarthritis only) Chorea Erythema marginatum Subcutaneous nodules	Carditis (clinical or subclinical) Arthritis (including polyarthritis, monoarthritis, or polyarthralgia[c]) Chorea Erythema marginatum Subcutaneous nodules
Minor Criteria	
Polyarthralgia Fever (≥38.5°C) ESR ≥60 mm in the first hour and/or CRP ≥3.0 mg/dL Prolonged PR interval, after accounting for age variability (unless carditis is a major criterion)	Monoarthralgia Fever (≥38°C) ESR ≥30 mm in the first hour and/or CRP ≥3.0 mg/dL[d] Prolonged PR interval, after accounting for age variability (unless carditis is a major criterion)

Joint manifestations are only considered in either the major or minor categories, but not both in the same patient.

[a]Annual ARF incidence of ≤2 per 100,000 school-aged children or all age RHD prevalence of ≤1 per 1000 people per year.

[b]Defined as echocardiographic.

[c]Polyarthralgia should only be considered as a major manifestation in moderate- and high-risk populations after exclusion of other causes.

[d]CRP value must be greater than the normal laboratory upper limit. In addition, as the ESR might evolve during the course of ARF, peak ESR values should be used.

ARF, Acute rheumatic fever; *CRP,* C-reactive protein; *ESR,* erythrocyte sedimentation rate; *RHD,* rheumatic heart disease.

ANSWER TO QUESTION 663

D (Braunwald, pp. 1848, 1856, 1859; Table 94.1)

Rheumatoid arthritis (RA) is the most common systemic rheumatic disorder. Potential cardiac complications include pericardial, myocardial, coronary, or conduction system disease. The incidence of symptomatic pericarditis has declined (<2% of patients) with current aggressive management and increasing use of biologic therapies in RA, and asymptomatic pericardial effusions are more common than acute pericarditis. Very rarely, pericardial constriction develops.

Arrhythmias or conduction abnormalities (first-degree atrioventricular [AV] block, most commonly) are not unusual in RA, occurring in up to 50% of patients, but are rarely symptomatic. Conduction disease may result from impingement on the conduction fibers by rheumatoid nodules, or in the case of AV block, by rare rheumatic myocarditis or amyloid deposition.

Patients with RA have an increased incidence of atherosclerotic coronary artery disease (CAD), likely related to both traditional risk factors and disease-related inflammation. Symptoms of CAD may be masked in RA patients with limited physical mobility, but the risk for myocardial infarction is similar to that of diabetics. Women with RA are twice as likely as age-matched controls to suffer myocardial infarction. In the past, coronary arteritis had been reported in up to 20% of patients in autopsy series; however, in the current anti-inflammatory era, it is only rarely of clinical significance. The epicardial arteries are generally spared, because arteritis is usually confined to smaller intramyocardial vessels.

Autopsy studies have demonstrated rheumatoid involvement of the cardiac valves, but such lesions are only occasionally identified clinically. Valvular thickening may be evident echocardiographically, more commonly in patients with seropositive RA and prominent extra-articular nodular disease.

ANSWER TO QUESTION 664

C (Braunwald, pp. 1841–1843)

A major goal of therapy in patients with atrial fibrillation (AF) is to prevent thromboembolic complications such as stroke. This patient is at increased risk for thromboembolism in the setting of AF because of his age, hypertension, and diabetes (CHA_2DS_2-VASc score = 4) and therefore warrants chronic anticoagulation therapy.

Dabigatran etexilate is an oral direct thrombin inhibitor that reduces the risk of stroke and systemic embolism in patients with nonvalvular AF. In the RE-LY trial, dabigatran (at doses of 110 and 150 mg twice daily) was compared prospectively with warfarin (dose adjusted to achieve an international normalized ratio between 2.0 and 3.0) for stroke and systemic embolism prevention in 18,113 patients with nonvalvular AF, followed for a median of 2 years. The annual rate of stroke or systemic embolism was 1.7% with warfarin, 1.5% with the lower-dose dabigatran regimen ($P < .001$), and 1.1% with the higher-dose regimen ($P < .001$). The lower-dose dabigatran regimen was noninferior to warfarin, whereas the higher dose regimen was actually superior for stroke and embolism prevention. The annual rates of major bleeding were 3.4% with warfarin compared with 2.7% and 3.1% with the lower-dose and higher-dose dabigatran regimens, respectively. That is, the lower-dose dabigatran regimen was associated with less major bleeding than warfarin, whereas the rates were similar in the higher-dose dabigatran and warfarin cohorts. Episodes of hemorrhagic stroke were significantly fewer with either dose of dabigatran compared with warfarin.

The most common gastrointestinal side effects of dabigatran are dyspepsia and gastritis; hepatotoxicity was not observed with dabigatran in the RE-LY trial.

The labeling for dabigatran recommends a dose adjustment to 75 mg twice daily for patients with a reduced creatinine clearance between 15 and 30 mL/min. There is insufficient experience to recommend a dose for a creatinine clearance <15 mL/min.

ANSWER TO QUESTION 665

B (Braunwald, p. 1819; Fig. 92.7)

Amiodarone, a potent class III antiarrhythmic agent, has two primary effects on thyroid function. First, it inhibits the peripheral conversion of thyroxine (T_4) to triiodothyronine (T_3), causing a reduction of serum T_3 and a transient rise in thyroid-stimulating hormone (TSH). Within a short time, however, a compensatory increase in serum T_4 levels occurs and TSH returns to normal. Clinically, such patients are euthyroid, even though T_4 levels are elevated. Amiodarone's second effect relates to its large content of iodine (30% by weight), which inhibits synthesis and release of T_4 from the thyroid gland, causing a more sustained rise in TSH. In some patients, especially those with underlying thyroid disease, clinical hypothyroidism and a marked rise in TSH result.

Amiodarone-induced hyperthyroidism is less common and may arise from two distinct mechanisms. Type I develops primarily in individuals with underlying thyroid disease, typically in iodine-deficient environments. Such patients display evidence of thyroid autoimmunity, including antithyroid antibodies. In contrast, type II is a form of thyroiditis that develops in a previously normal gland, presumably mediated by proinflammatory cytokines, marked by an elevation of circulating interleukin-6. This condition is a thyroid-destructive process, and hyperthyroidism results from release of preformed thyroid hormone, a situation that can persist for months. Unlike type I, this form of hyperthyroidism tends to respond to glucocorticoid therapy.

ANSWER TO QUESTION 666

D (Braunwald, pp. 1726–1727, 1729–1730, 1732; see also Answer to Question 486)

The two principal sleep disorders associated with cardiovascular disease are obstructive sleep apnea (OSA) and

central sleep apnea (CSA). OSA is characterized by transient upper airway occlusion that results in partial or complete cessation in airflow leading to hypoxia, sympathetic activation, repeated arousal and wakefulness, and sleep fragmentation. Individuals with OSA demonstrate persistently heightened sympathetic activity, even during daytime wakefulness. This in turn leads to peripheral vasoconstriction and hypertension, as well as automatic tachycardias driven by the augmented sympathetic tone. In addition, reflex parasympathetic activity can lead to profound nocturnal bradycardias.

Continuous positive airway pressure (CPAP) is the cornerstone of OSA management. This therapy effectively splints open the airway, thus preventing airway collapse, improving nocturnal hypoxia, and reducing sympathetic activity. Randomized controlled trials of CPAP in OSA have demonstrated decreased daytime sleepiness, improved health-related quality-of-life and mood, and lower blood pressure.[1] While observational trials have suggested decreased mortality with CPAP usage, randomized trials to date have not confirmed that.[2,3] Importantly, such trials have been limited by either inadequate power or modest CPAP adherence.

In contrast to OSA, CSA represents an instability of ventilatory control, resulting in oscillations in ventilation with periodic hyperpnea and apnea.[4] When manifest as Cheyne-Stokes respirations, it is associated with advanced heart failure. CPAP is effective in the management of CSA, is associated with decreased sympathetic drive, reduced ventricular afterload, and improvement in left ventricular ejection fraction. CPAP has been shown to improve nocturnal oxygen saturation and 6-minute walk distance in patients with class II to IV heart failure and CSA.

ANSWER TO QUESTION 667

B (Braunwald, pp. 1692–1693; Table 84.7)

Approximately 20% of patients with unprovoked deep venous thrombosis experience a recurrence within 2 years of stopping anticoagulation therapy. Therefore, after the initial treatment period of at least 3 months, many experts recommend extended-duration anticoagulation. In a randomized trial of patients who had completed 6 to 12 months of anticoagulation for acute venous thromboembolism (VTE), both standard-dose apixaban (5 mg twice daily) and low-dose apixaban (2.5 mg twice daily) were shown to reduce the rate of recurrent VTE compared to placebo without increasing major bleeding.[1] Similarly, extended-duration treatment with rivaroxaban (20 mg daily) in patients who had completed 6 to 12 months of anticoagulation for VTE reduced the rate of recurrent VTE compared to placebo in the EINSTEIN DVT Continued Treatment trial.[2] More recently, in the EINSTEIN CHOICE trial, extended-duration treatment with either standard-dose rivaroxaban (20 mg daily) or low-dose rivaroxaban (10 mg daily) reduced the rate of recurrent VTE compared to aspirin.[3] Extended-duration anticoagulation with both standard-intensity warfarin (international normalized ratio [INR] target 2.0 to 3.0) or low-intensity warfarin (INR target 1.5 to 2.0) are also valid evidence-based options for extended-duration anticoagulation.[4] However, in contrast to the non-vitamin K antagonist oral anticoagulants, dosing of vitamin K antagonists requires close monitoring and dose adjustment rather than fixed dosing.

Two studies have tested low-dose aspirin (100 mg daily) versus placebo in patients with unprovoked VTE who had completed at least 6 months of standard anticoagulation.[5,6] In a meta-analysis, there was a 32% reduction in the rate of recurrence of VTE with aspirin during a median follow-up of >2 years, without an increase in major bleeding. Thus, while patients with unprovoked VTE derive the lowest recurrence rates with extended-duration standard anticoagulants, aspirin offers an evidence-based benefit for patients who do not wish to restrict their lifestyle or be subject to the bleeding risk of indefinite-duration standard anticoagulation.

ANSWER TO QUESTION 668

B (Braunwald, pp. 102–103, 108)

When surgery is elective, it is appropriate to estimate cardiovascular risk using multifactorial indices. Independent predictors of complications with noncardiac surgery include (1) high-risk type of operation, (2) history of ischemic heart disease, (3) history of heart failure, (4) history of stroke, (5) diabetes with preoperative insulin use, and (6) preoperative serum creatinine >2 mg/dL. An example of a high-risk operation is abdominal aortic aneurysm surgery, whereas low-risk procedures include endoscopy, cataract surgery, superficial procedures and biopsies, and transurethral prostate surgery. Carotid endarterectomy poses an intermediate risk.

Ischemic heart disease is a major determinant of perioperative morbidity and mortality. However, if a patient is clinically stable, and can carry a grocery bag up one flight of stairs (the equivalent of >4 METS of activity) without stopping or experiencing anginal symptoms, most surgical procedures will be well tolerated and no additional preoperative cardiac testing is typically necessary. Conversely, a patient who develops shortness of breath or chest discomfort with only minor exertion is at high risk for postoperative cardiac events

and warrants additional cardiac testing, especially if more than a minor surgical procedure is planned.

Historically, the cardiac risk of noncardiac surgery in patients with prior myocardial infarction (MI) has related inversely to the length of time that has passed since the acute coronary event. Studies from the 1970s concluded that purely elective surgery should be delayed for 6 months after an MI to ensure that cardiovascular risk had returned to baseline. In those studies, the risk of reinfarction or death was approximately 30% when patients were operated on within 3 months of an MI, but only 5% when 6 months had elapsed before the operation. Later studies, in the era of careful perioperative monitoring, demonstrated much lower cardiac complication rates: approximately 6% risk of reinfarction for operations performed within 3 months of an MI and 2% risk for operations performed within 3 to 6 months. These historic risks are less relevant today in the era of early revascularization (mechanical or fibrinolytic) and aggressive postevent pharmacologic therapy for acute coronary syndromes (ACS). Current guidelines suggest that the highest risk of elective surgery for such patients is limited to the first 30 days after an ACS while the disrupted coronary plaque and myocardium are healing.

ANSWER TO QUESTION 669

C (Braunwald, pp. 1589, 1790; see also Answer to Question 636)

The presentation of this patient is most consistent with peripartum cardiomyopathy (PPCM). This disorder is a form of dilated cardiomyopathy that manifests in the last trimester of pregnancy or in the early postpartum period. The incidence is higher in women >30 years of age, women with twin pregnancies, multiparous women, and African American women. Recent studies have suggested significant overlap in the genetic predisposition to PPCM and other forms of idiopathic dilated cardiomyopathy.

The prognosis of this disorder is favorable compared with other forms of dilated cardiomyopathy, with approximately 50% of patients showing marked improvement or complete recovery within 6 months postpartum. The remainder either stabilizes with reduced cardiac function or declines progressively, eventually requiring cardiac transplantation. The predictors for a poor outcome include older age, higher parity, severe left ventricular dilatation, and onset of symptoms later after delivery. There is a high risk of relapse of PPCM in subsequent pregnancies, and that risk appears to be greatest in women who have persistently impaired cardiac function.

ANSWERS TO QUESTIONS 670 TO 674

670–E, 671–D, 672–B, 673–C, 674–A (Braunwald, pp. 1850, 1857–1859, 1862)

The spondyloarthropathies, including ankylosing spondylitis, reactive arthritis, and psoriatic arthritis, have a predilection for arthritis of the sacroiliac and lumbosacral joints. These diseases are associated with the histocompatibility antigen HLA-B27 and occur predominantly in men. *Ankylosing spondylitis* is the most common of these syndromes to involve the heart and classically causes dilatation of the aortic valve ring with fibrous thickening and inflammation.[1] The aorta in ankylosing spondylitis is histologically similar to that in syphilitic aortitis, including adventitial scarring, intimal proliferation, and narrowing of the vasa vasorum. Aortic regurgitation results from thickening of the valvular cusps and dilatation of the aortic root. Conduction system disorders, due to fibrous infiltration in the atrioventricular node and the bundle of His, may be seen in ankylosing spondylitis as well.

Reactive arthritis is a form of nonpurulent arthritis that may follow enteric or urogenital infections. It may be accompanied by uveitis/conjunctivitis and nongonococcal urethritis (formerly termed Reiter syndrome). The cardiac complications of reactive arthritis are similar to those of ankylosing spondylitis.[2]

Cardiac abnormalities in patients with *systemic sclerosis/scleroderma* often relate to systemic or pulmonary hypertension, but may also include myocardial fibrosis and contraction band necrosis, causing diastolic and/or systolic ventricular dysfunction. Symptomatic pericarditis occurs in 7% to 20% of patients. Conduction defects and thickening of the mitral and aortic valves may also occur.[3]

Giant cell arteritis predominantly causes inflammation of the aorta, its major branches, and coronary arteries. Weakening of the vessels may lead to dilatation, aneurysm formation, and valvular insufficiency. The vascular pathology often reveals granuloma formation.[4]

Behçet syndrome is a multisystem disorder characterized by recurrent oral and genital ulcers and uveitis. The ulcers are often painful and necrotic, and eye involvement occasionally progresses to blindness. The etiology of the disease is unclear, but appears to involve endothelial activation as a mediator of vascular inflammation. Venous and arterial thrombosis may occur, as well as aneurysm formation of the large vessels. Diffuse aortitis in Behçet syndrome can lead to aortic root dilatation and valvular insufficiency.[5]

ANSWERS TO QUESTIONS 675 TO 678

675–C, 676–B, 677–D, 678–A (Braunwald, pp. 677, 1831, 1833, 1837)

Numerous cardiac medications can cause adverse effects. For example, heparin can result in thrombocytopenia by two main mechanisms as described in the Answer to Question 659.

A positive direct Coombs test is seen in up to 10% of patients who receive alpha-methyldopa, an antihypertensive that is sometimes used in pregnancy. In these patients, IgG antibody is directed against the Rh complex of red cells. Hemolysis may be severe but improves within several weeks after cessation of the medication.

The most common side effects of ticagrelor, a platelet $P2Y_{12}$ receptor inhibitor, are bleeding, dyspnea (~15% of patients in the PLATO trial),[1] and ventricular pauses, which are typically asymptomatic. Dyspnea, when present, usually occurs soon after initiating therapy and is self-limited. The mechanism is unknown.

Procainamide may cause a syndrome resembling systemic lupus erythematosus (SLE). Symptoms consist of polyarthralgias, pleuritis, and photosensitive rashes. Unlike conventional SLE, nephritis and central nervous system complications are very rare. Patients with drug-induced lupus are antinuclear antibody (ANA) positive with antibodies to histones but rarely display hypocomplementemia or antibodies to DNA. Discontinuation of procainamide typically results in improvement of symptoms within a few days to weeks. However, ANA levels may remain elevated for years.

ANSWERS TO QUESTIONS 679 TO 683

679–C, 680–A, 681–B, 682–B, 683–C (Braunwald, pp. 1850–1852; see also Answers to Question 632 and Question 633)

Takayasu arteritis (TA), also termed *pulseless disease*, is of unknown etiology and is characterized by marked fibrous and degenerative scarring of the elastic fibers of the vascular media.[1] It most commonly involves the aorta and carotid arteries. The disease is 10 times more common in women than in men, and in most patients onset occurs during the teen years. Patients typically present initially with malaise, weight loss, night sweats, arthralgias, pleuritic pain, anorexia, and fatigue. Regardless of whether a patient goes through this initial phase, symptoms and signs referable to the obliterative and inflammatory changes in affected blood vessels begin to appear following a latent period. These include diminished or absent pulses with claudication (upper extremities > lower extremities), hypertension (related to renal artery stenosis or increased vessel rigidity), and aortic root aneurysms with aortic regurgitation. Common laboratory abnormalities include elevated sedimentation rate, low-grade leukocytosis, and normocytic anemia. Treatment includes glucocorticoid therapy. Patients with refractory symptoms may respond to azathioprine, mycophenolate mofetil, methotrexate, leflunomide, intravenous cyclophosphamide, tumor necrosis factor antagonists, or tocilizumab (an interleukin-6 receptor antagonist).

Giant cell arteritis (GCA; also termed temporal arteritis) is a disease of unknown etiology characterized by granulomatous inflammation of large- to medium-caliber arteries with a special predilection for the vessels of the head and neck.[2] It arises primarily in elderly people with a female predominance. Clinically, the triad of severe headache, fever, and marked malaise characterizes the illness. The headaches are often severe and are typically localized over involved temporal arteries. Claudication of the jaw muscles during chewing is present in up to two-thirds of patients. Involvement of the ophthalmic artery leads to visual symptoms and may result in irreversible blindness. The syndrome of polymyalgia rheumatica, consisting of diffuse muscular aching and stiffness, occurs in about 40% of patients with GCA. In a minority of cases, involvement of the aorta or its major branches may lead to symptoms and signs similar to those of TA, although renal artery involvement is rare in GCA.

Patients with GCA appear ill and are almost always febrile. Affected vessels feel abnormal to palpation and are tender, allowing experienced examiners to make the diagnosis of temporal arteritis at the bedside by identifying an indurated, beaded, tender temporal artery. Laboratory tests often reveal a very high erythrocyte sedimentation rate, normochromic, normocytic anemia, and elevated acute-phase reactants. Biopsy of an involved temporal artery confirms the diagnosis.

Management of GCA includes early intervention with high-dose steroid therapy followed by a gradual taper to a maintenance dose, which is typically continued for 1 to 2 years. Early administration of steroid therapy is crucial to prevent involvement of the ophthalmic arteries and possible blindness. Recent evidence suggests that combining tocilizumab with steroid therapy may lead to higher rates of sustained remission in GCA.[3]

ANSWERS TO QUESTIONS 684 TO 688

684–C, 685–A, 686–B, 687–D, 688–E (Braunwald, pp. 1641–1645; Table 81.1)

Many chemotherapeutic agents have potential cardiovascular toxicities. The anthracyclines (e.g., doxorubicin, daunorubicin, and idarubicin) may cause acute cardiac effects (including atrial and ventricular arrhythmias and pericardial effusion) or more chronic impairment (dilated cardiomyopathy with heart failure). As described in the Answer to Question 544, heart failure due to anthracycline therapy is dose related and develops more frequently when concurrent risk factors are present, including prior heart disease, radiation therapy exposure to the heart, and use of other cardiotoxic chemotherapeutic agents (e.g., trastuzumab, paclitaxel).

Patients receiving 5-fluorouracil may experience acute chest pain and myocardial infarction during or immediately after infusion. The mechanism of this adverse effect is

unknown. Cyclophosphamide and ifosfamide are alkylating agents that can cause an acute hemorrhagic myopericarditis. Interleukins, which are potent modulators of the immune system, are associated with capillary leak syndrome, hypotension, noncardiogenic pulmonary edema, and nephrotoxicity.

Sunitinib is a tyrosine kinase inhibitor that targets vascular endothelial cell growth factor receptors and is used to inhibit progression of renal cell carcinoma and gastrointestinal stromal tumors. Hypertension is a common side effect, with marked elevation in blood pressure in 8% to 20% of patients.

ANSWERS TO QUESTIONS 689 TO 693

689–C, 690–D, 691–E, 692–A, 693–B (Braunwald, pp. 1809–1810, 1812, 1815–1818)

Endocrine disorders often exhibit cardiovascular manifestations. Excess thyroid hormone levels result in tachycardia, palpitations, and hypertension, often with a widened pulse pressure.[1] Cardiac examination reveals a hyperdynamic impulse with an accentuated S_1. Systolic murmurs are common, and a *Means-Lerman scratch,* a grating systolic sound at the upper left sternal border, may be auscultated during expiration.

The cardiovascular manifestations of hypothyroidism include bradycardia, diastolic hypertension with a narrowed pulse pressure, cardiomegaly with a reduced ejection fraction, and pericardial effusion, which only rarely results in tamponade physiology.[1]

Cushing syndrome, a state of augmented glucocorticoid exposure, is associated with accelerated atherosclerosis, likely related to hypertension and hyperglycemia in this condition. *Carney complex* is a genetic syndrome that includes cardiac myxomas, pigmented dermal lesions, and endocrine overactivity that can include Cushing syndrome. This autosomal-dominant condition arises from mutations in the *PRKAR1A* gene, which encodes a regulatory subunit of protein kinase A.[2]

Hyperaldosteronism is associated with excess aldosterone production from an adrenal or extra-adrenal source. Hypertension, hypokalemia, and metabolic alkalosis are common findings.[3] Many of the cardiac findings are nonspecific and are a consequence of the metabolic and electrolyte abnormalities. For example, U waves and ventricular arrhythmias result from associated hypokalemia.

Parathyroid hormone has direct inotropic and chronotropic effects on the heart, likely due to increased myocyte calcium entry. Hypercalcemia associated with hyperparathyroidism may result in excess calcium deposition in the heart, hypertension, and shortening of the QT interval.[4]

ANSWERS TO QUESTIONS 694 TO 697

694–B, 695–C, 696–D, 697–A (Braunwald, pp. 1843–1844)

Tissue-type plasminogen activator (tPA), the major physiologic activator of plasminogen, is both synthesized naturally by endothelial cells and produced commercially by recombinant DNA technology for the purpose of therapeutic fibrinolysis. The protein is synthesized in a single-chain form, which is subsequently converted to a two-chain form by proteolytic cleavage of a single plasmin-sensitive site. Both the single-chain and the two-chain forms have endogenous proteolytic activity. The alpha chain of tPA is derived from the amino-terminal portion of single-chain tPA and contains a pair of finger-like structures referred to as "kringle" domains. Lysine binding sites located on these domains confer binding specifically for fibrin. As a result, tPA is a relatively fibrin-specific activator that converts plasminogen to plasmin two or three times more efficiently in the presence of fibrin. The protease domain of tPA contains a proteolytic site responsible for this conversion. This portion is homologous with other serine proteases, such as urokinase and trypsin.

Urokinase is a two-chain serine protease that is synthesized in both renal tubular epithelial cells and endothelial cells. While urokinase converts plasminogen to plasmin by hydrolyzing the same bond as that acted on by tPA, the proteolytic activity of urokinase is not enhanced by the presence of fibrin. Therefore, urokinase may activate circulating plasminogen as effectively as plasminogen absorbed onto fibrin thrombi.

Streptokinase is a single polypeptide chain of 414 amino acids that is produced by a strain of hemolytic streptococci. Streptokinase does not cause thrombolysis by intrinsic enzymatic activity. Instead, it activates the fibrinolytic system by combining with plasminogen to form a plasminogen activator complex that is then capable of converting plasminogen to plasmin. Plasmin then degrades fibrin and other procoagulant proteins. Many individuals have circulating antibodies to streptokinase as a result of previous streptococcal infections. Therefore, a large dose of streptokinase is administered to neutralize these antibodies. Antistreptococcal antibodies may remain high for up to 6 months after administration.

Tenecteplase is a genetically engineered mutant form of tPA that displays a prolonged half-life and increased fibrin specificity. Unlike tPA, which requires a continuous infusion, tenecteplase is injected as a single intravenous bolus, which facilitates administration.

TABLE 5.6 Advantages of Low-Molecular-Weight Heparin Over Unfractionated Heparin

ADVANTAGE	CONSEQUENCE
Better bioavailability and longer half-life after subcutaneous injection	Can be given subcutaneously once or twice daily for both prophylaxis and treatment
Dose-independent clearance	Simplified dosing
Predictable anticoagulant response	Monitoring of coagulation is unnecessary in most patients
Lower risk for HIT	Safer than heparin for short- or long-term administration
Lower risk for osteoporosis	Safer than heparin for long-term administration

HIT, Heparin-induced thrombocytopenia.

ANSWERS TO QUESTIONS 698 TO 702

698–A, 699–B, 700–D, 701–C, 702–A (Braunwald, pp. 1835–1838)

Unfractionated heparin (UFH) is a naturally occurring compound that acts in vivo by combining with antithrombin (an inhibitor of thrombin and factors X, IX, and XI). The conformational change that occurs in antithrombin allows for an accelerated interaction with the activated clotting factors, limiting thrombin generation and fibrin formation. Commercial heparin is extracted from porcine intestinal mucosa and bovine lung and does not inactivate clot-bound thrombin or factor VII. Heparin is not absorbed by the gastrointestinal tract and is therefore administered in intravenous or subcutaneous forms. The bioavailability of subcutaneous injections of UFH is only 30%.

The activated partial thromboplastin time (aPTT) test is used to determine the inhibitory effect of UFH. For acute thrombosis or embolism, intravenous heparin is administered with a goal aPTT of 1.5 to 2 times the control value. Subcutaneous UFH is often used for patients who require a lower level of anticoagulation. Heparin therapy's major complication is bleeding. There is up to a 30% incidence of heparin-induced thrombocytopenia (HIT) that may be associated with thromboembolic events and often resolves with discontinuation of the drug (see Answer to Question 659). In addition, heparin may cause osteoporosis, elevated liver enzymes, increased vascular permeability, alopecia, and hypoaldosteronism (and associated hyperkalemia).

Low-molecular-weight heparin (LMWH) also produces an anticoagulant effect by binding to antithrombin. However, in distinction to UFH, LMWH preferentially inhibits factor Xa more than thrombin. LMWH formulations bind less with platelet factor 4, plasma proteins, and endothelial cells, and therefore have >90% bioavailability when administered by subcutaneous injection. Other advantages of LMWH include a prolonged half-life and predictable anticoagulant responses (Table 5.6).

Patients receiving LMWH do not require serial laboratory monitoring of the anticoagulant effect, except in the presence of renal failure, extreme obesity, or pregnancy. HIT can occur with LMWH but is less common than with UFH.

ANSWERS TO QUESTIONS 703 TO 706

703–D, 704–B, 705–A, 706–C (Braunwald, pp. 1850, 1858–1860, 1862; see also Answers to Question 670 to Question 674)

Rheumatologic disorders often involve the cardiovascular system and can result in pericardial, myocardial, valvular, or arterial abnormalities. Aortic involvement is estimated to occur in 15% of patients with giant cell arteritis. Inflammation often involves the proximal aorta and aortic valve cusps, resulting in dilatation of the vessel and aortic regurgitation.[1] Other rheumatologic diseases that prominently involve the aorta include ankylosing spondylitis and psoriatic arthritis.

Valvular abnormalities are found by transesophageal echocardiography in 50% of patients with systemic lupus erythematosus. The most common involvement, termed *Libman-Sacks endocarditis,* represents noninfectious valve thickening, usually on the atrial side of the mitral valve and the arterial side of the aortic valve. Over time, fibrosis may result in valvular insufficiency. Much less commonly, the vegetations may occlude the valve orifice, causing stenosis. Clinical manifestations of Libman-Sacks lesions, such as infective endocarditis or peripheral embolism, are rare.[2]

Although pulmonary hypertension can develop in many rheumatologic disorders, it is a particularly prominent feature of systemic sclerosis and is one of the leading causes of morbidity and mortality in that condition.[3] Behçet disease typically results in inflammation of the thoracic aorta and branch vessels, leading to stenoses and aneurysmal dilatation of the subclavian and carotid arteries.[4] Thoracic and abdominal aortic aneurysms may also result.

Notice: The indications and dosages of all drugs in this book have been recommended in the medical literature and conform to the practices of the general community. The medications described do not necessarily have specific approval by the Food and Drug Administration for use in the diseases and dosages for which they are recommended. The package insert for each drug should be consulted for use and dosage as approved by the FDA. Because standards for usage change, it is advisable to keep abreast of revised recommendations, particularly those concerning new drugs.

Preface

The impetus for writing this book came from our observations that many health care professionals and young physicians working in emergency rooms, intensive and coronary care units were unable to interpret simple pacemaker electrocardiograms correctly. Over the years we also heard many complaints from beginners in the field of cardiac pacing that virtually all, if not all, the available books are too complicated and almost impossible to understand. Indeed, the ever-changing progress in electrical stimulation makes cardiac pacing a moving target. Therefore we decided to take up the challenge and write a book for beginners equipped with only a rudimentary knowledge of electrocardiography and no knowledge of cardiac pacing whatsoever. Because many individuals first see the pacemaker patient after implantation, the book contains little about indications for pacing and implantation techniques. The book starts with basic concepts and progressively covers more advanced aspects of cardiac pacing including troubleshooting and follow-up.

As one picture is worth a thousand words, this book tries to avoid unnecessary text and focuses on visual learning. We undertook this project with the premise that learning cardiac pacing should be enjoyable. Cardiac pacing is a logical discipline and should be fun and easy to learn with the carefully crafted illustrations in this book. The artwork is simple for easy comprehension. Many of the plates are self-explanatory and the text in the appendix only intends to provide further details and a comprehensive overview.

Many of the images used to create the illustrations in this book are taken from CorelDraw and Corel Mega Gallery clipart collections.

We are grateful to Charlie Hamlyn of Blackwell Publishing and Tom Fryer of Sparks for their superb work in the production of this book.

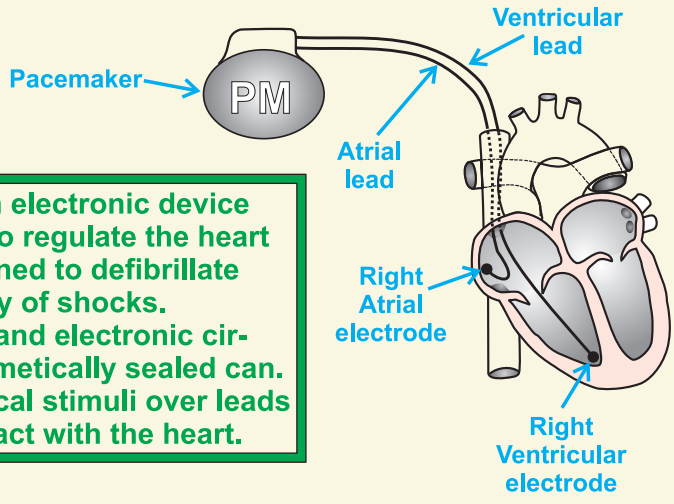
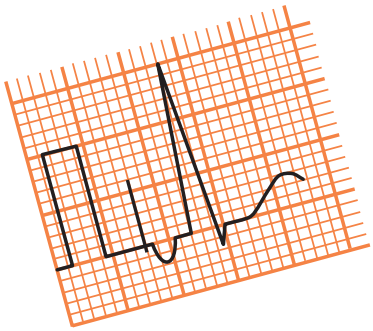
Alfons F. Sinnaeve

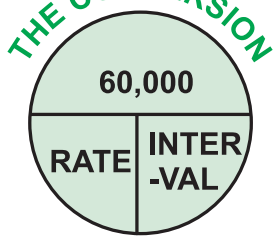
WHAT IS A PACEMAKER ???



A pacemaker (PM) is an electronic device implanted in the body to regulate the heart beat. A PM is not designed to defibrillate the heart by the delivery of shocks.
It consists of a battery and electronic circuits enclosed in a hermetically sealed can. The PM delivers electrical stimuli over leads with electrodes in contact with the heart.

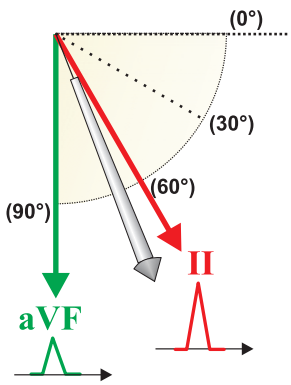
A. F. Sinnaeve

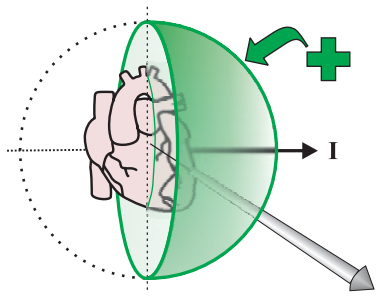




RECORDING PACEMAKER ACTIVITY

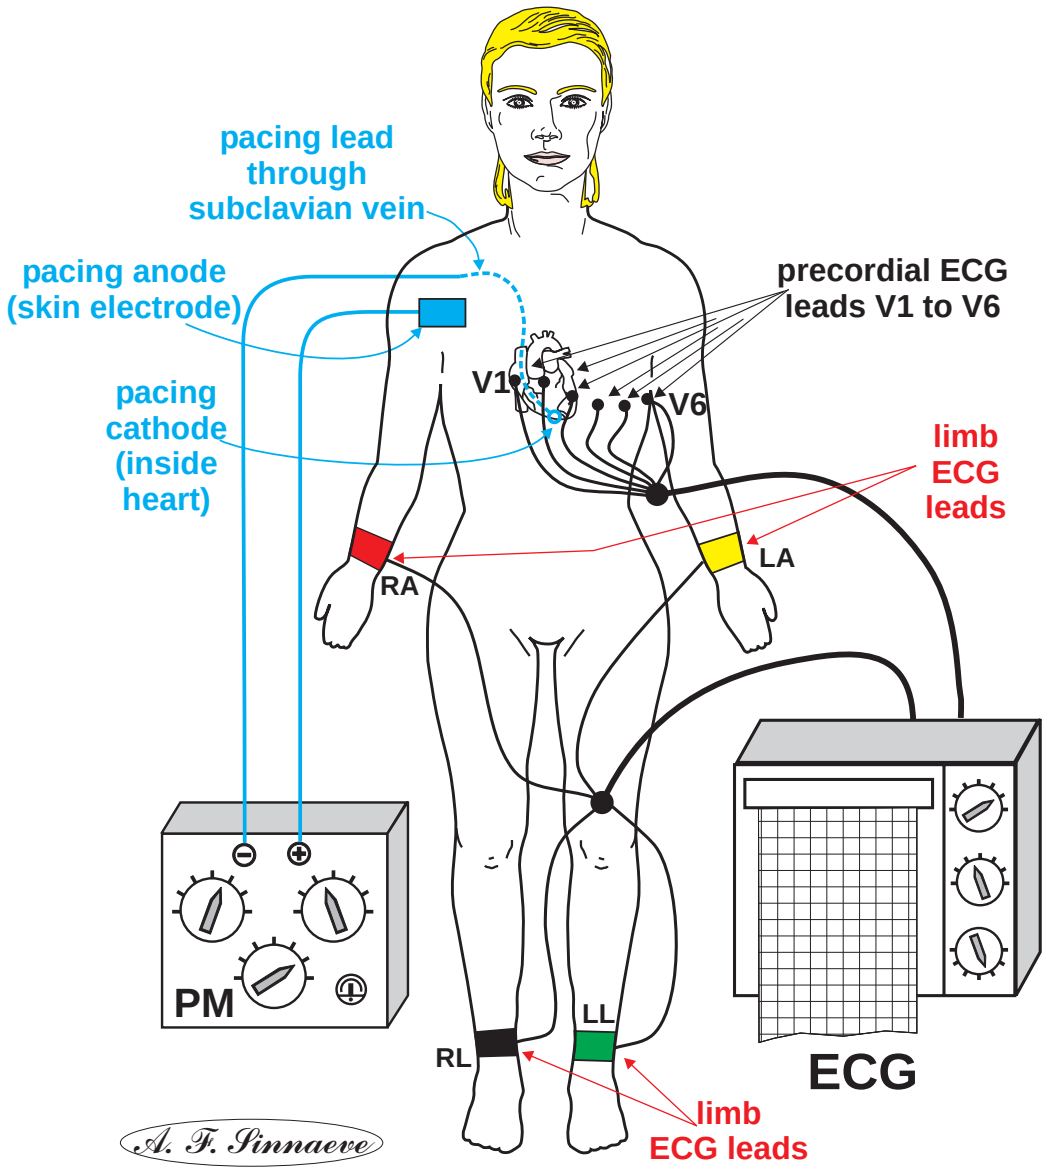
* 12-lead ECG during transvenous pacing
* Standard chest electrode positions
* Grid for measuring intervals
* The electrical axis in the frontal plane
* Determination of the mean frontal plane axis 1
* Determination of the mean frontal plane axis 2
* A rule of thumb for the mean frontal plane axis





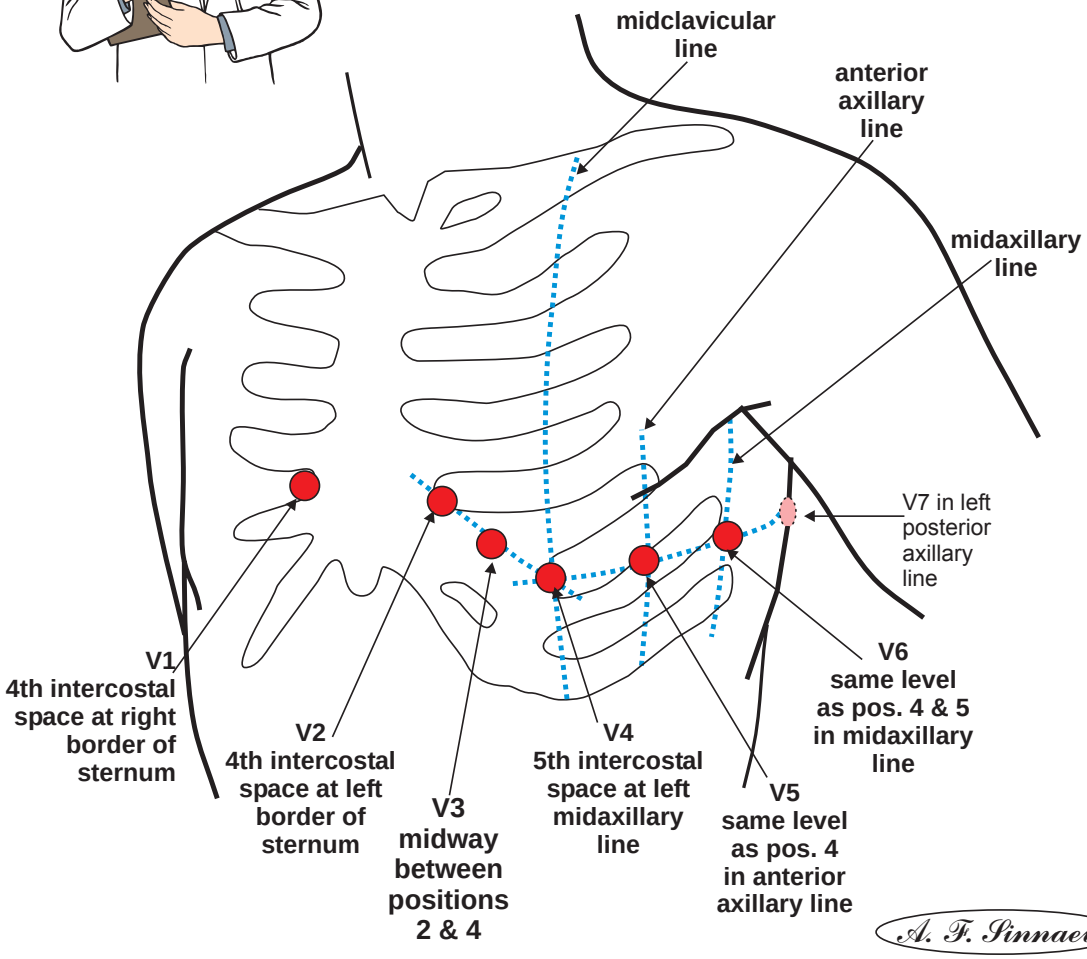
A. F. Sinnaeve

CONFIGURATION OF 12-LEAD ECG DURING TRANSVENOUS PACING



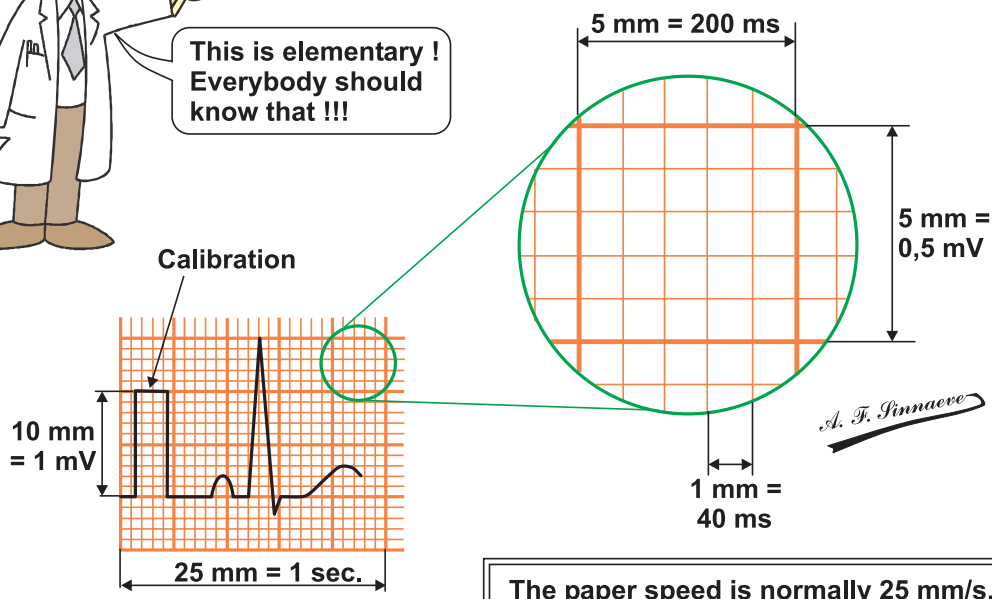
STANDARD CHEST ELECTRODE POSITIONS

The right position of all the electrodes is extremely important !!!

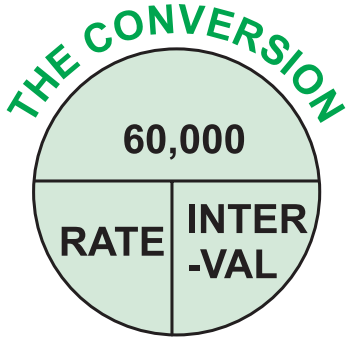


A. F. Sinnaeve

TIMING INTERVALS VERSUS RATE



The paper speed is normally 25 mm/s, thus 1 mm on the paper corresponds with 1/25 s = 0.04 s = 40 ms



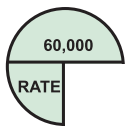
UNITS OF TIME

1 minute = 60 seconds
or 1 min = 60 s
1 second = 1,000 milliseconds
or 1 s = 1,000 ms
1 minute = 60,000 milliseconds
or 1 min = 60,000 ms

RATE is expressed in beats per minute or bpm

$$\text{RATE (in bpm)} = \frac{60{,}000}{\text{INTERVAL (in ms)}}$$

The pacemaker rate is the average of several intervals calculated for 1 minute of time

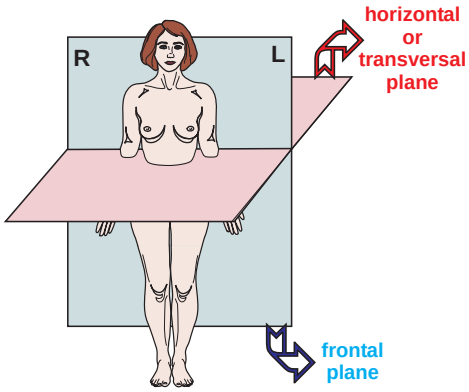


$$\text{INTERVAL (in ms)} = \frac{60{,}000}{\text{RATE (in bpm)}}$$

An interval is the time between two consecutive events, e.g. Vp-Vp or Vs-Vs

Abbreviations : min = minute ; mm = millimeter ; ms = millisecond ; mV = millivolt ; s = second ; Vp = ventricular paced event ; Vs = ventricular sensed event

THE ELECTRICAL AXIS IN THE FRONTAL PLANE



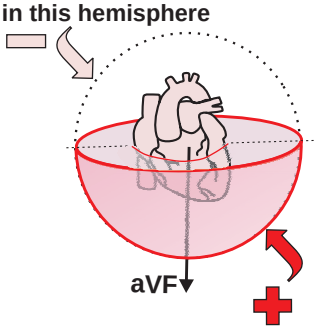
At any time during depolarization, there is a resultant instantaneous vector which represents the electrical activity of the depolarization process of all the ventricular myocardium. As depolarization proceeds, the magnitude and direction of this instantaneous vector varies continuously.
The mean frontal plane vector or axis represents the summation of all the instantaneous vectors recorded in the frontal plane that occur during depolarization, and is depicted as a single mean vector.

Why is the frontal plane axis important during pacing ?

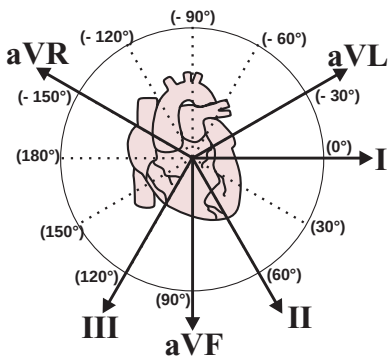
Because it can help locate the 4 important sites of stimulation which are the RV apex, RV outflow tract, LV and biventricular (i.e. simultaneous RV and LV) pacing.

To determine the mean frontal plane axis, you have to understand the frontal plane diagram and arrangement of the frontal plane ECG leads. You also have to understand the hemisphere concept of the various frontal plane ECG leads. If the mean QRS vector or axis is situated in the positive (+) hemisphere of a particular lead, this ECG lead will show a positive (+) deflection

Lead aVF will be negative if the mean QRS vector is in this hemisphere

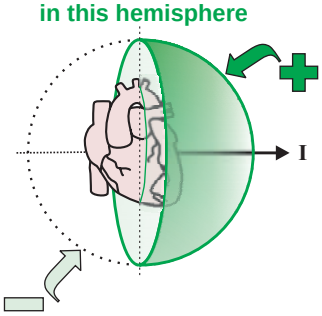


Lead aVF will be positive if the mean QRS vector is situated in this hemisphere



A. F. Sinnaeve

Lead I will be positive if the mean QRS vector is situated in this hemisphere

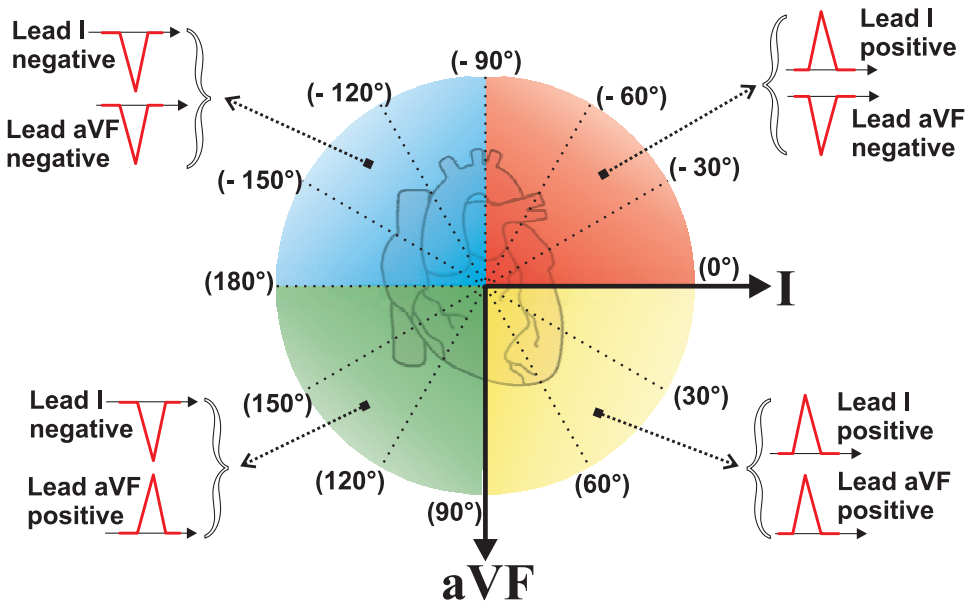


Lead I will be negative if the mean QRS vector is in this hemisphere

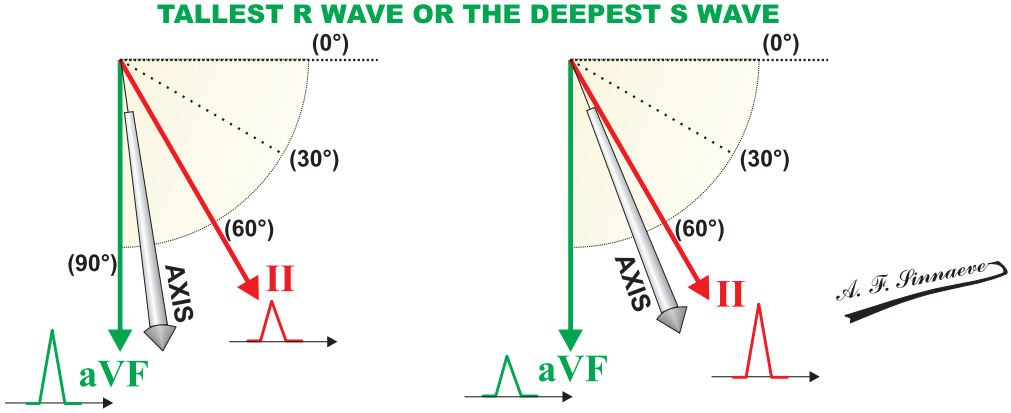
DETERMINATION OF THE MEAN FRONTAL PLANE AXIS

JUST REMEMBER 3 IMPORTANT QUESTIONS :
* In which quadrant is the QRS vector situated ?
* Which of the adjacent leads has the tallest R wave or the deepest S wave ?
* Which is the most equiphasic lead (or zero lead)?

STEP 1 : LOOK AT LEADS I & aVF TO DETERMINE IN WHICH QUADRANT THE FRONTAL PLANE AXIS IS SITUATED



STEP 2 : LOOK IN THE APPROPRIATE QUADRANT FOR THE TALLEST R WAVE OR THE DEEPEST S WAVE

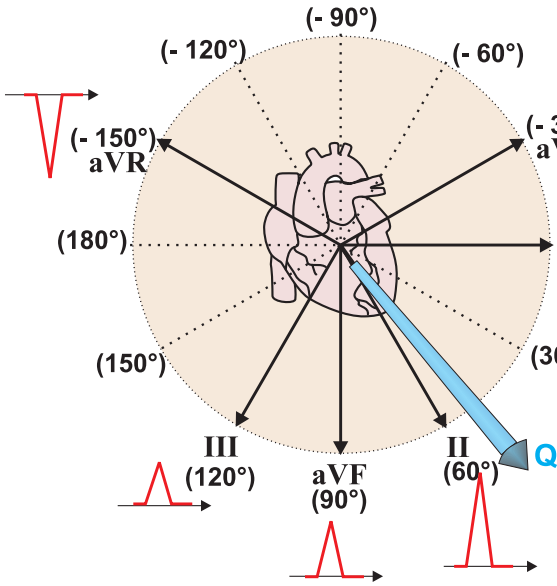


A. F. Sinnaeve

The lead nearest to (or parallel along) the QRS axis has the largest positive deflection. If two leads have equal positive deflections, the axis is exactly in the middle between these two leads.

DETERMINATION OF THE MEAN FRONTAL PLANE AXIS CONT'D

STEP 3 : LOOK FOR THE MOST EQUIPHASIC LEAD (where the positive minus the negative defection is closest to zero)
THIS LEAD IS PERPENDICULAR TO THE QRS AXIS



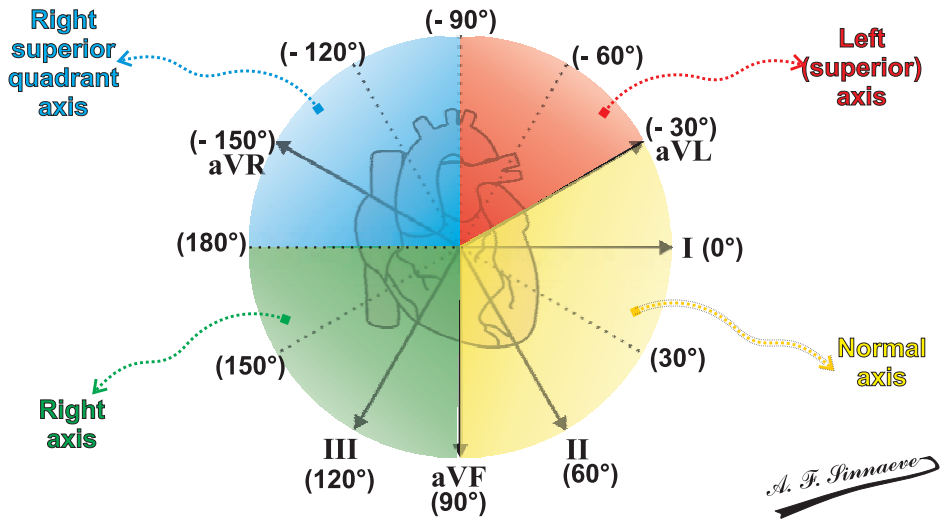
aVL is equiphasic
Lead aVL is perpendicular to the QRS axis

Lead I is positive, thus the QRS axis is on the left

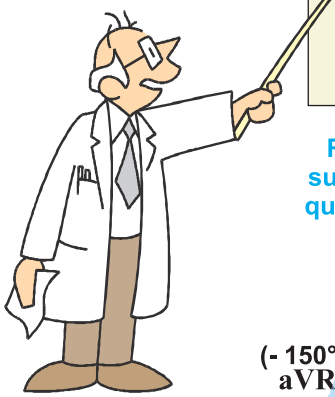
QRS axis in the frontal plane

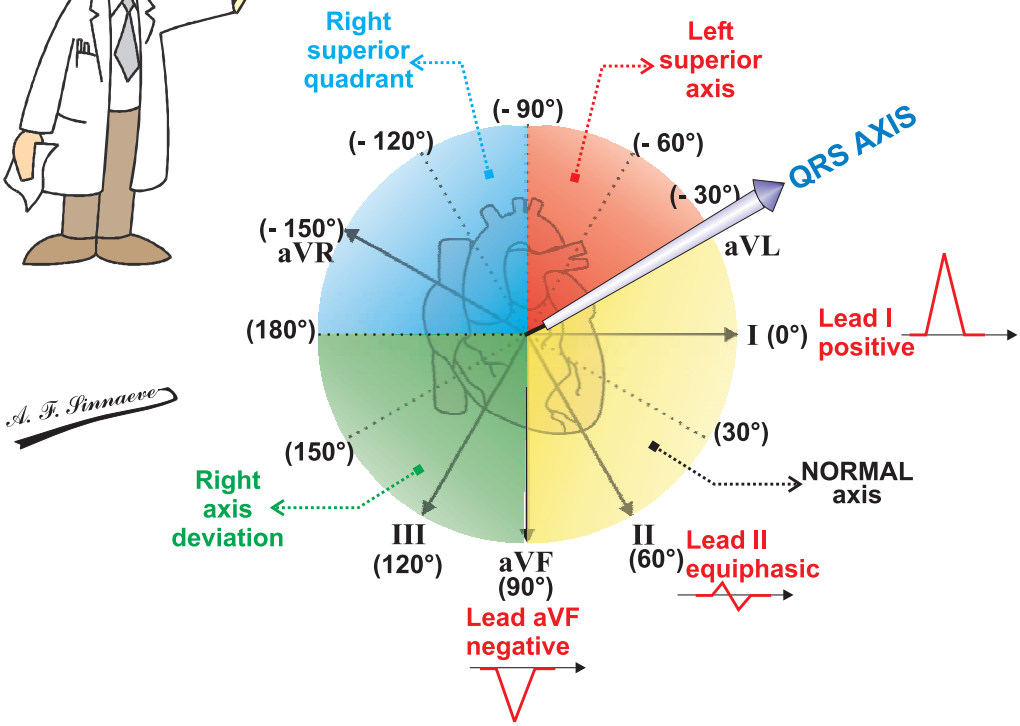
QRS axis is along lead II. Note that lead II has the largest positive deflection, confirming the direction of the axis.

SUMMARY : the QRS axes of the heart (not paced)



RULE OF THUMB FOR DETERMINING THE FRONTAL PLANE AXIS
LOOK AT LEADS I AND aVF





1/ If both leads I and aVF are positive (dominant R wave), the axis is normal (yellow area)

2/ If lead I is positive and lead aVF is negative, you must look at lead II

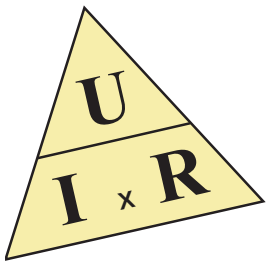
a. If lead II is equiphasic (positivity is equal to negativity so that the algebraic sum is zero), the axis is directed along lead aVL. This because an equiphasic lead (lead II in this case) is perpendicular to the axis (along lead aVL)

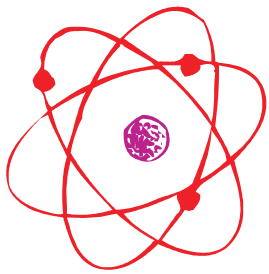
b. If lead II is more positive than negative, the axis is below -30° and normal (yellow area)

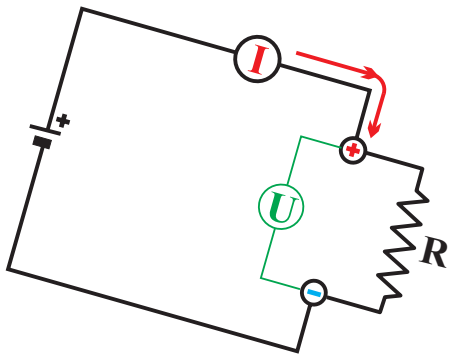
c. If lead II is more negative than positive, the axis is more negative than -30° and is in the left superior quadrant (red area)

3/ If lead I is negative (down) and aVF is positive (up) the axis is in the right inferior quadrant (green area - right axis deviation)

4/ If leads I and aVF are negative (down), the axis is in the right superior quadrant (blue area). The axis is simply described as being in the right superior quadrant. It is called neither extreme right nor extreme left axis deviation.

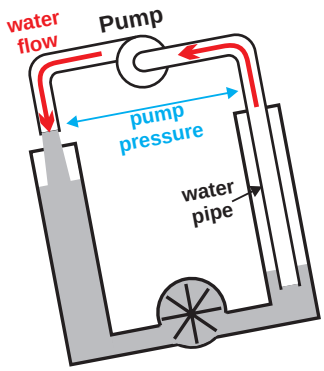


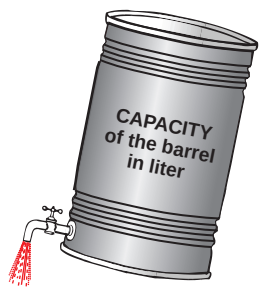




FUNDAMENTALS of ELECTRICITY

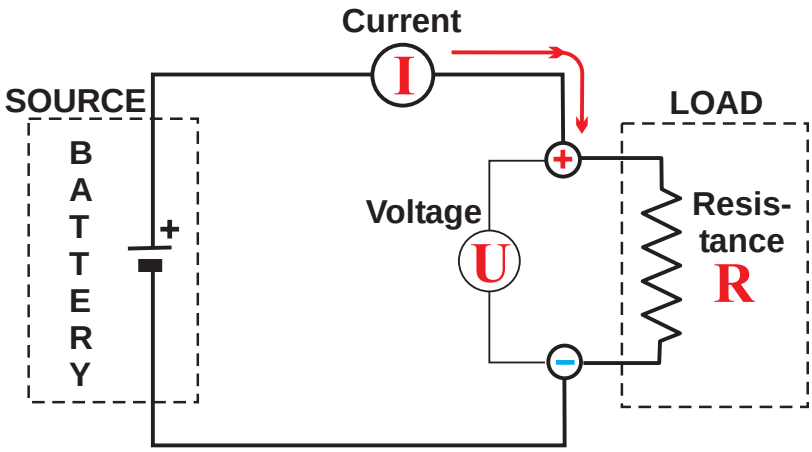
* Ohm's law
* Water equivalent
* Impedance
* Common units for pacemaker variables
* Battery 1
* Battery 2
* Battery impedance and battery voltage
* Battery capacity





OHM's LAW

This is the most important law of electricity !!!
Everybody should be familiar with these three variables, their relation and their units !



U = voltage (in volt V)

I = current (in ampere A)

R = resistance (in ohm Ω)

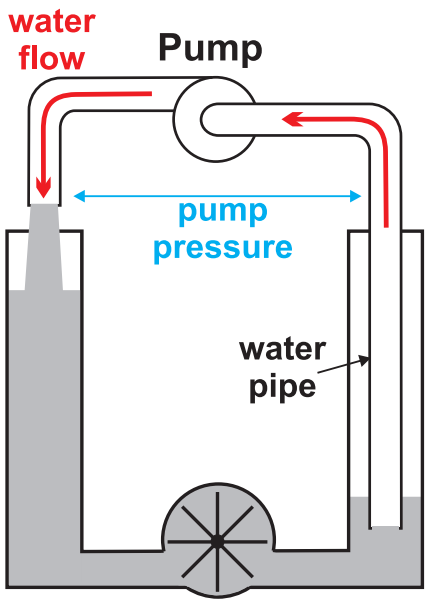
Voltage

Current

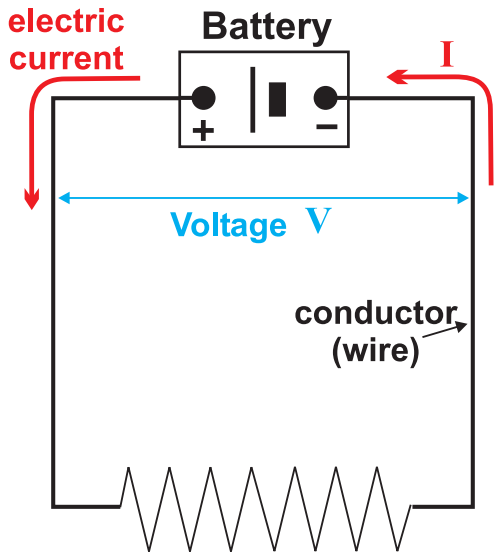
Resistance

A. F. Sinnaeve

THE WATER EQUIVALENT

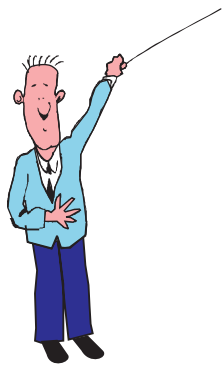


water mill
resisting the water flow



RESISTANCE to
the flow of electrons

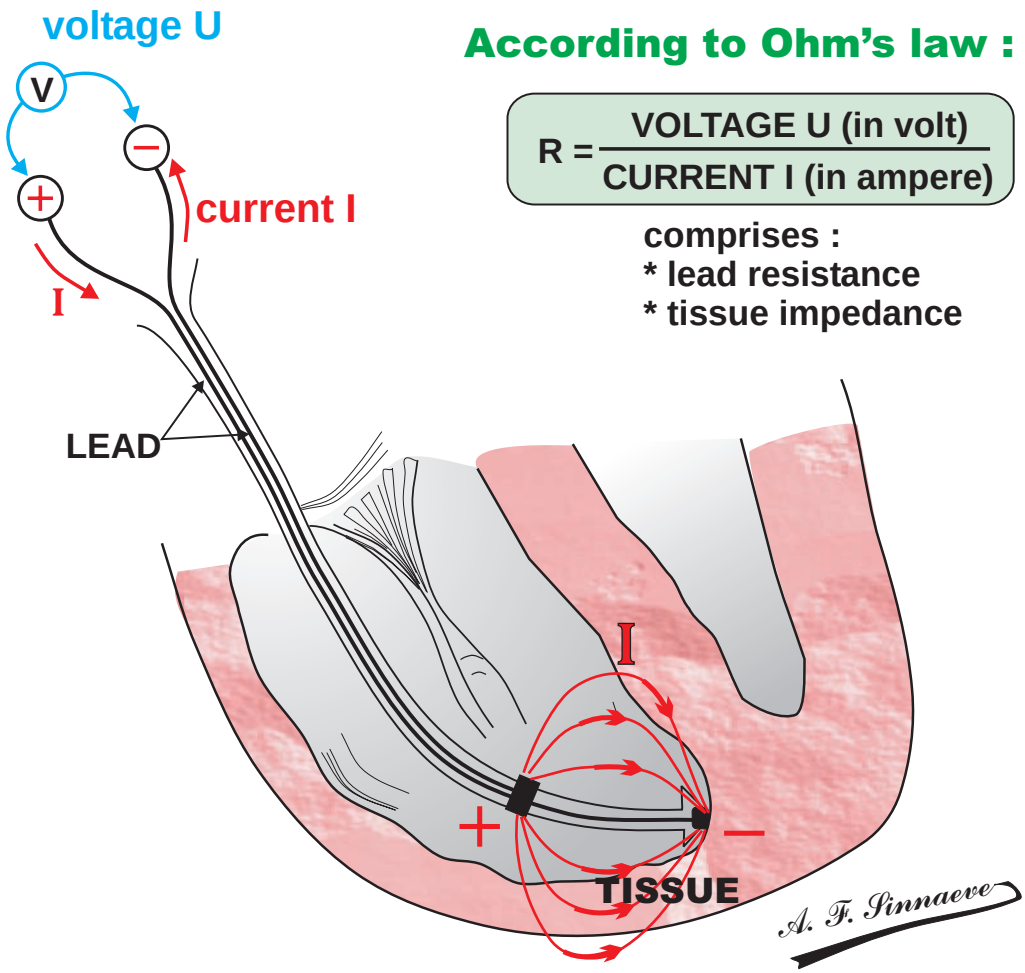
WATER	ELECTRICITY
* waterpump	* battery
* pump pressure	* voltage
* quantity of water	* electric charge
* liter	* ampere.second
* **flow of water**	* **electric current**
* liter per sec	* ampere
* water pipe	* wire
* resistance	* resistance



Note for the electricians :
ampere.second (As) = coulomb (C)

A. F. Sinnaeve

PACING IMPEDANCE



According to Ohm's law :

$$R = \frac{\text{VOLTAGE U (in volt)}}{\text{CURRENT I (in ampere)}}$$

comprises :
* **lead resistance**
* **tissue impedance**

INSULATION DEFECT < 250Ω	NORMAL PACING IMPEDANCE ca. 500Ω	LEAD FRACTURE > 1000Ω

Note for electricians :
The pacing impedance is not purely resistive (the tissue impedance is capacitive) and should be indicated by a Z. In the clinical practice only the absolute value or magnitude of the pacing impedance is considered and since it is expressed in "OHM" according to Ohm's law, most people simply call it "resistance"

COMMON UNITS FOR PACEMAKERS

VOLTAGE

Basic unit : volt - symbol V

Sometimes used : millivolt - symbol mV

1 V = 1,000 mV or 1 mV = $\frac{1}{1{,}000}$ V = 10^{-3} V

CURRENT

Basic unit : ampere - symbol A

Used stimulus amplitude : milliampere - symbol mA

1 A = 1,000 mA or 1 mA = $\frac{1}{1{,}000}$ A = 10^{-3} A

Used for battery current drain : microampere - symbol μA

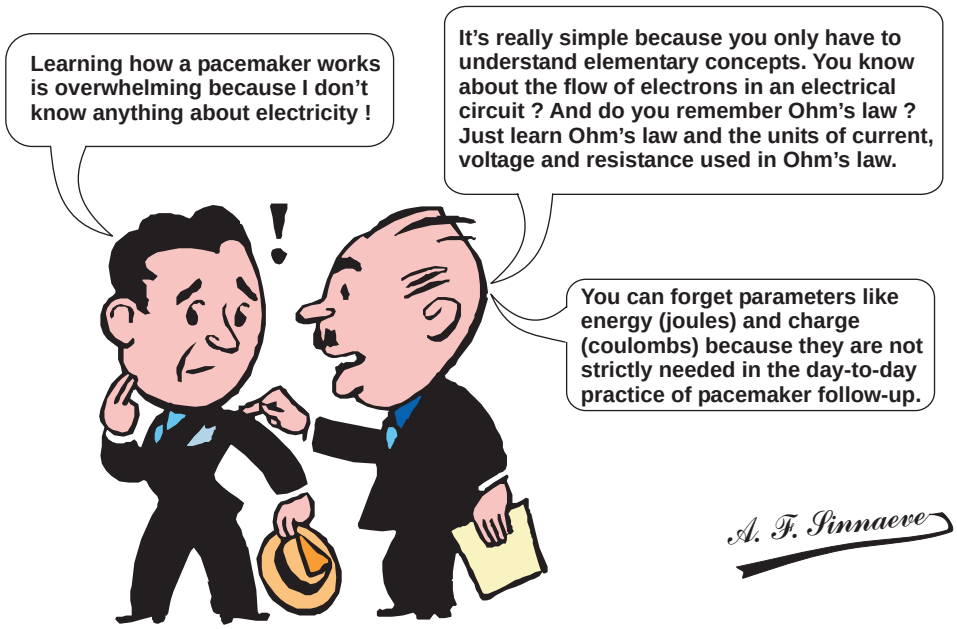
1 A = 1,000,000 μA or 1 μA = $\frac{1}{1{,}000{,}000}$ A = 10^{-6} A

RESISTANCE

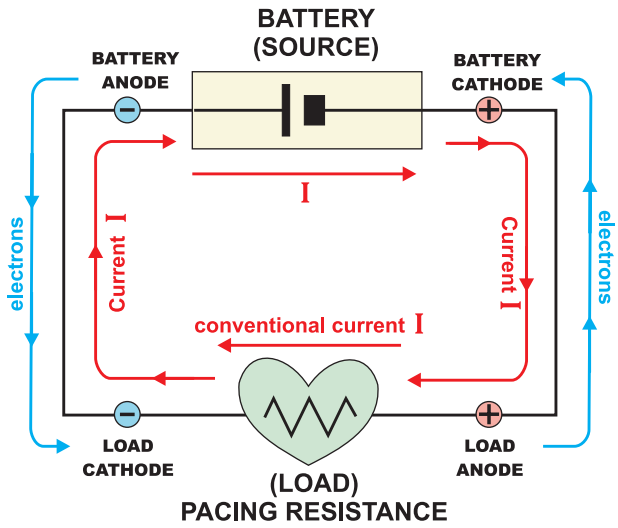
Basic unit : ohm - symbol Ω

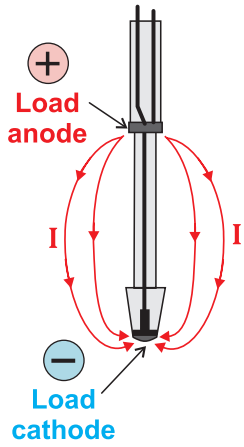
Sometimes used : kilo-ohm - symbol kΩ

1 Ω = $\frac{1}{1{,}000}$ kΩ or 1 kΩ = 1,000 Ω = 10^{3} Ω



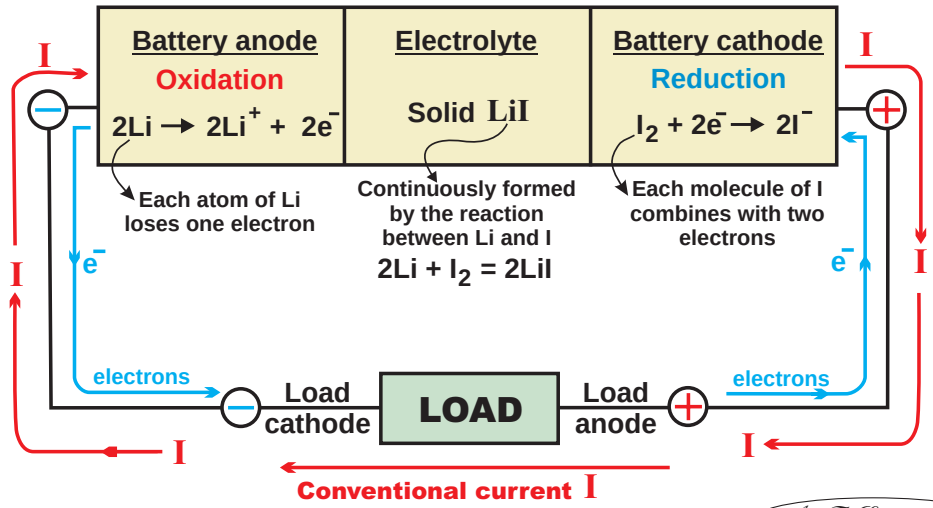
ANODE - CATHODE & ELECTRIC CURRENT





* First, you have to know that electric current only flows if the circuit is closed and that the external resistance or load limits the current.
* Second, you have to understand that in a closed circuit the **electrons** flow from the negative pole of the battery, through the load and back to the positive pole of the battery. However, **conventional electric current** flows in the opposite direction from the + pole of the battery via the load to its - pole. That's a historical convention dating from the time electrons weren't yet discovered.
* Third, just remember that the battery is the source delivering electricity while the load consumes electricity. If you follow the circuit, you will see that the anode is always the electrode by which the electrons leave (A for anode in "Away"). The cathode on the contrary, is always the electrode into which the electrons enter or come (C for cathode in "Come"). That's easy isn't it ? This terminology applies to both the battery and the load !

The Lithium - Iodine battery

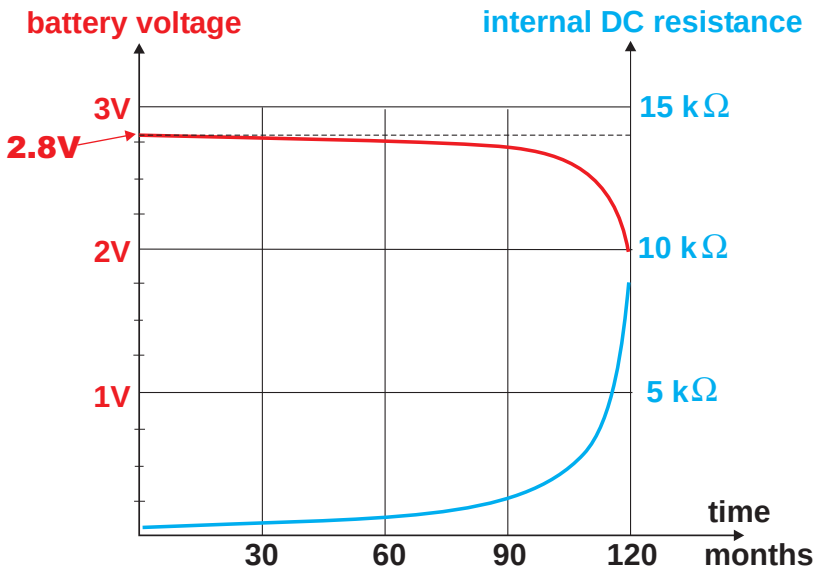


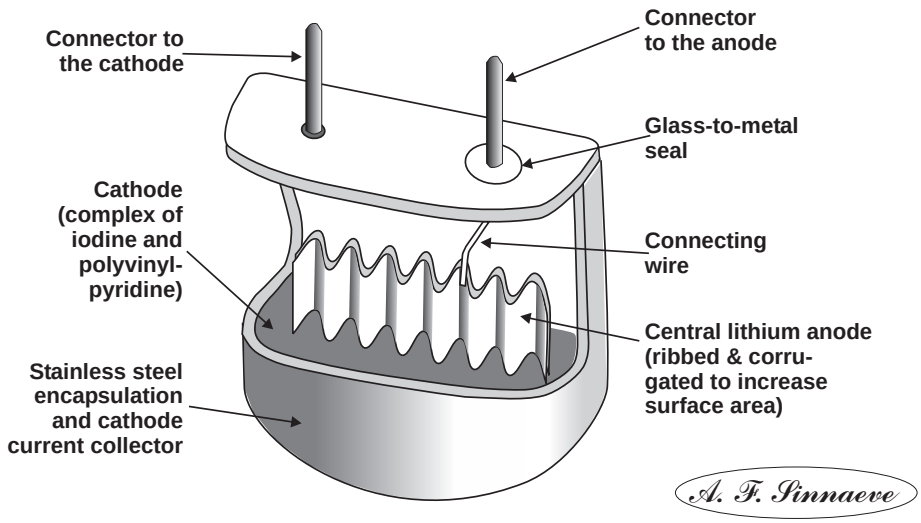
A. F Sinnaeve

How about the lithium-iodine battery ? Someone told me that no electrons can flow through that battery ?

Yes, that's true, but it isn't difficult to understand. The anode of a lithium-iodine battery is the place where electrons free themselves from lithium atoms to form Li^+ ions. With the electrolyte of the battery serving as an electron barrier and all electrons being negative and repelling each other, the electrons are pushed outside the battery to start their journey through the electrical circuit.
Following the electrical conductors, the electrons enter the load via its cathode. Just as a liquid, electricity cannot be compressed. So, an equal amount of electrons is leaving the load via its anode, being attracted by the positive pole of the battery. The electrons enter the battery cathode where they combine with iodine I_2 to form $2I^-$ ions.
Inside the battery, the electrical circuit is closed by the flow of the Li^+ and I^- ions. These ions attract each other and diffuse through the electrolyte. When the two kinds of ions meet each other, they combine to form lithium-iodide LiI.
However, the lithium-iodide is not a good electrical conductor and so the buildup of this LiI increases the internal resistance of the battery.

The Lithium - Iodine battery





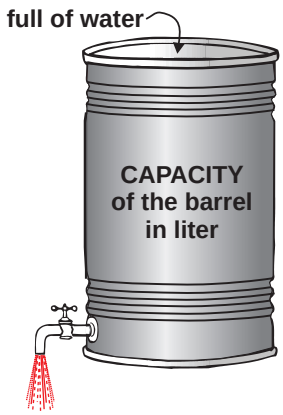
A. F. Sinnaeve

The anode of the battery produces lithium ions, while the cathode is producing iodine ions. These ions are moving to the other pole of the battery and are recombining to lithium iodide (LiI). This discharge product forms a barrier for the further movement of ions and thus an internal battery resistance is built up.
At the BOL the electrolyte barrier is thin with a low normal impedance. However, at the EOL the layer becomes thick and when the cathode material is almost depleted, the internal resistance is very high.

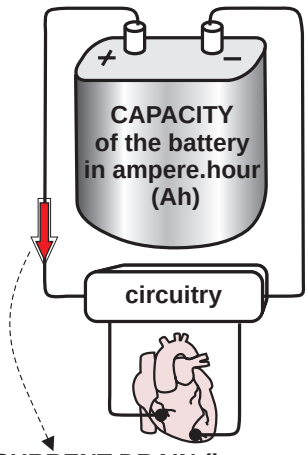
BOL = beginning-of-life ; **EOL =** end-of-life

BATTERY CAPACITY & LONGEVITY

LIFE EXPECTANCY = $\frac{\text{capacity}}{\text{drain}}$



OUTFLOW = DRAIN $\left(\frac{\text{liter}}{\text{minute}}\right)$



CURRENT DRAIN (in ampere A)
(1 ampere = 1,000,000 μA)
(1A = 10^6 μA)

e.g. **CAPACITY : 60 liters**
DRAIN : 0.5 liters/minute
EXPECTED TIME to empty the barrel:

$\frac{60}{0.5}$ **= 120 minutes**

= 2 hours

e.g. **CAPACITY : 2 ampere.hours = 2 Ah**
DRAIN : 25 μA = 25 *MICROAMPERE*
= 0.000025 A
EXPECTED LIFE TIME of the battery :

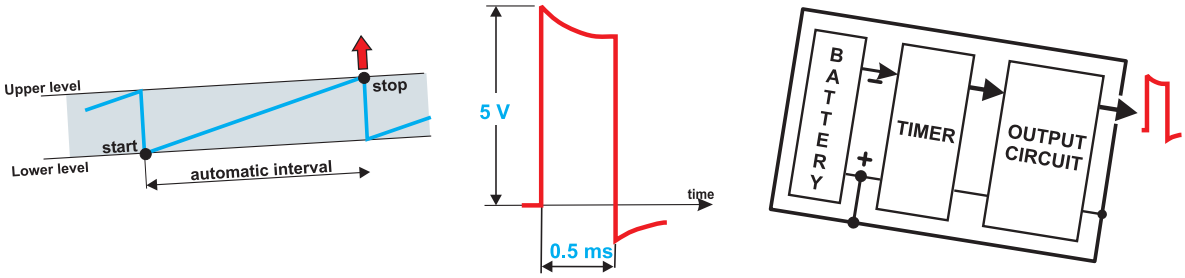
$\frac{2\ \text{Ah}}{0.000025\ \text{A}}$ **= 80,000 hours**

= about 9 years

Battery life expectancy increases if the current drain decreases by using :
*** pulses with a smaller voltage amplitude**
*** pulses with a shorter duration**
Hence the importance of determining the chronic pacing threshold so as to program the output voltage and pulse duration to provide an adequate safety margin and also conserve battery capacity to extend battery life

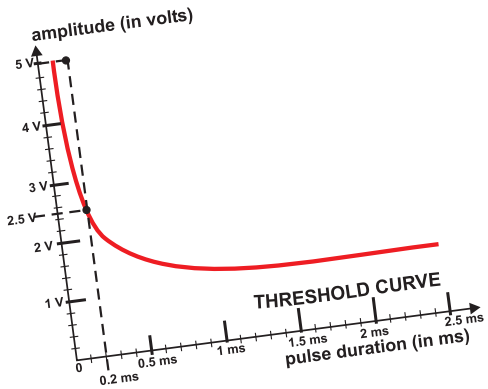
The output current of the pulses to the heart is expressed in mA (1 mA = 1/1,000 A)
The current drain of the battery is expressed in μA (1 μA = 1/1,000.000 A)
1 milliampere (mA) = 1,000 microampere (μA)

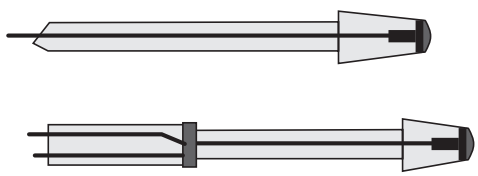
A. F. Sinnaeve



VENTRICULAR STIMULATION

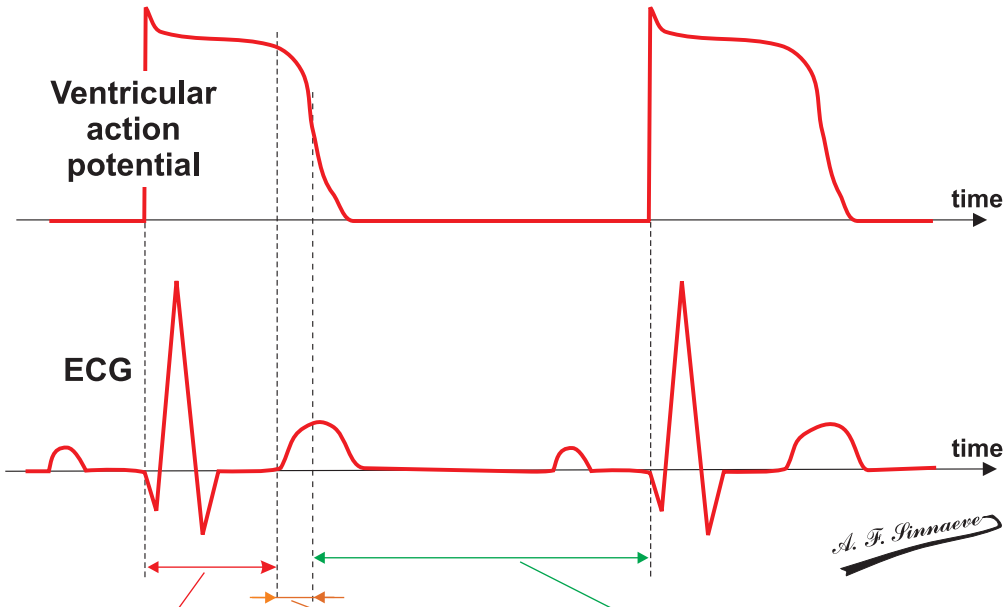
* Myocardial refractory period
* Asynchronous ventricular pacing (VOO)
* Ventricular depolarization by pacing
* The output pulse of the pacemaker
* The programmer and telemetry
* Panic button
* Programming amplitude and pulse width
* Determination of pacing threshold with constant pulse width
* Determination of pacing threshold with constant voltage
* Strength-duration curve
* Safety margin for capture
* Autocapture
* Bipolar vs unipolar pacing -
  - stimulus on analog recorder
* Variable stimulus appearance on digital recorder





Always keep in mind ! The myocardial refractory period refers to stimulation. In contrast the pace-maker refractory period refers to the sensing function of the device.

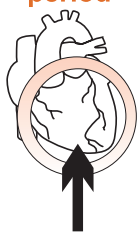
VENTRICULAR MYOCARDIAL REFRACTORY PERIOD



Absolute refractory period

No stimulus can activate the ventricle

Relative refractory period



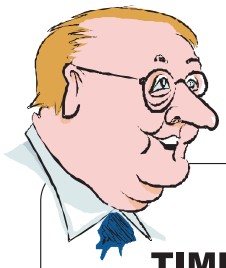
Only a stronger than normal stimulus can activate the ventricle

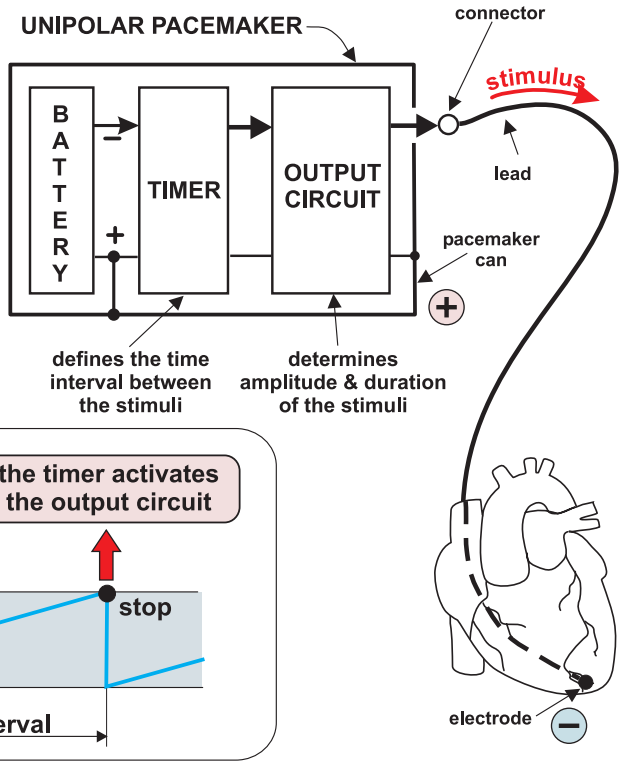
NORMAL

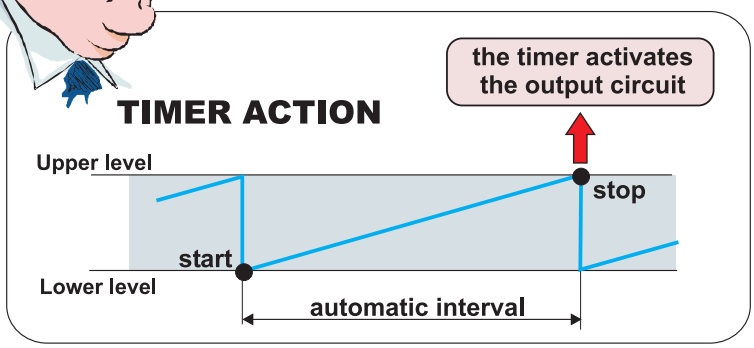
A normal stimulus activates the ventricular myocardium

ASYNCHRONOUS VENTRICULAR PACING (VOO)

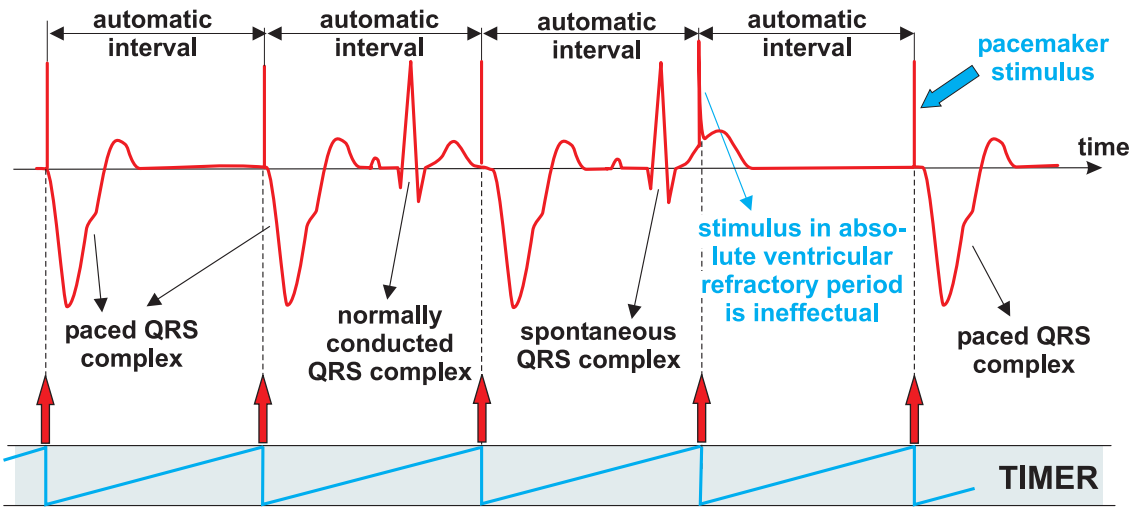
Note that the VOO mode causes a competitive rhythm because there is no sensing of spontaneous ventricular activity. Only stimuli beyond the ventricular myocardial refractory period cause successful capture !







ASYNCHRONOUS PACING with COMPETITIVE RHYTHM !!!



CAUTION

Modern pacemakers are non-competitive but assume asynchronous function only as long as a special magnet is placed over the pacemaker

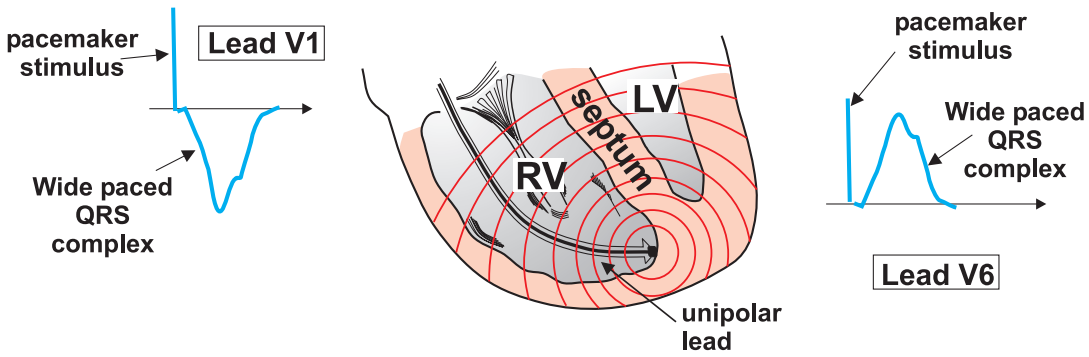
A. F. Sinnaeve

VENTRICULAR DEPOLARIZATION BY PACING

* The depolarization caused by the pacemaker does not occur via the specialized His-Purkinje network and propagates slower through ordinary myocardium
* The QRS complex is therefore wide like a ventricular extrasystole (premature ventricular contraction)

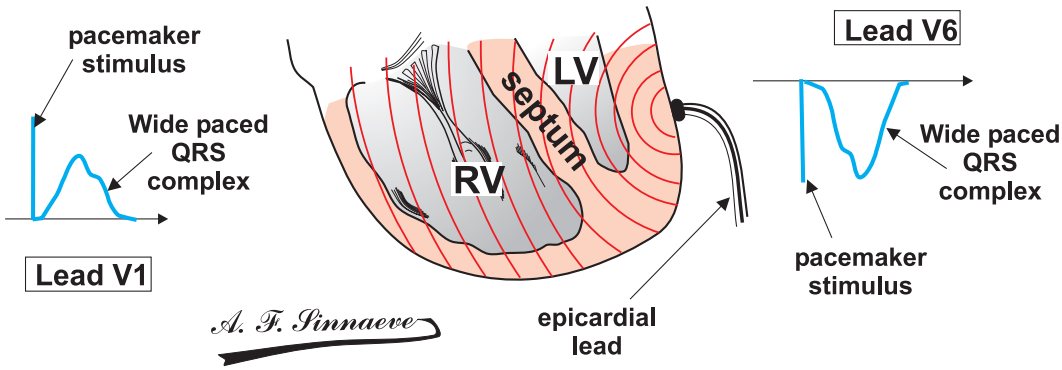
ENDOCARDIAL STIMULATION FROM RIGHT VENTRICLE

ECG resembles LBBB (LBBB = left bundle branch block)



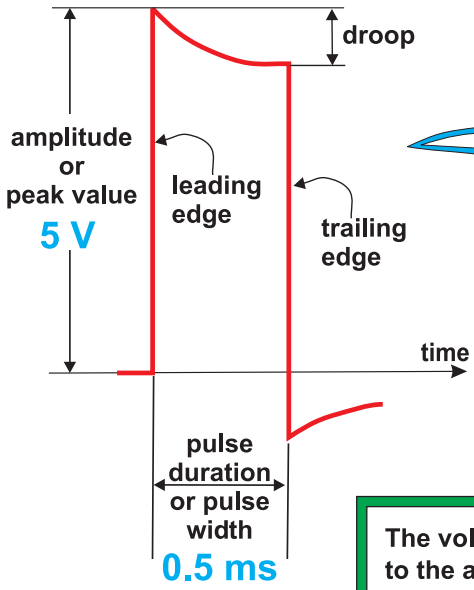
EPICARDIAL STIMULATION FROM LEFT VENTRICLE

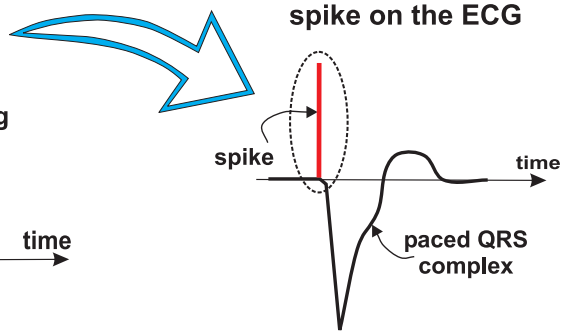
ECG resembles RBBB (RBBB = right bundle branch block)



A. F. Sinnaeve

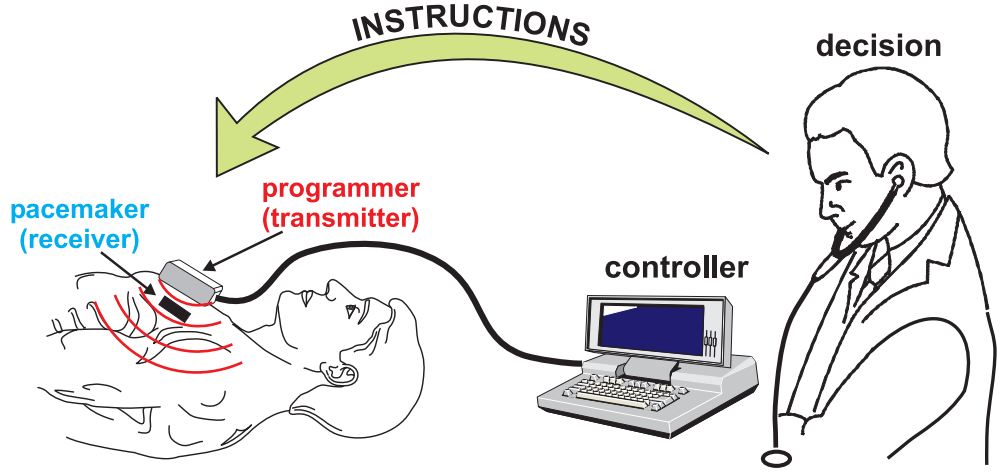
THE OUTPUT PULSE OF THE PACEMAKER





The voltage of a permanent pacemaker refers to the amplitude of the leading edge, which is always constant. It is actually closer to 5.4 V because the lithium iodine cell generates a voltage of 2.8 V which is then doubled electronically.
The droop is influenced by a variety of factors but visualization of the droop and trailing edge are not required for the management of patients.
The process does not terminate with the trailing edge. The pacemaker stimulus charges the electrode-tissue interface to a large voltage (polarization voltage) which is subsequently dissipated over a much longer period than the brief pacemaker stimulus. One must understand the existence of this “afterpotential” because it can play a role in problems associated with oversensing, i.e. unintended sensing of certain events.

PROGRAMMING : from controller to pacemaker

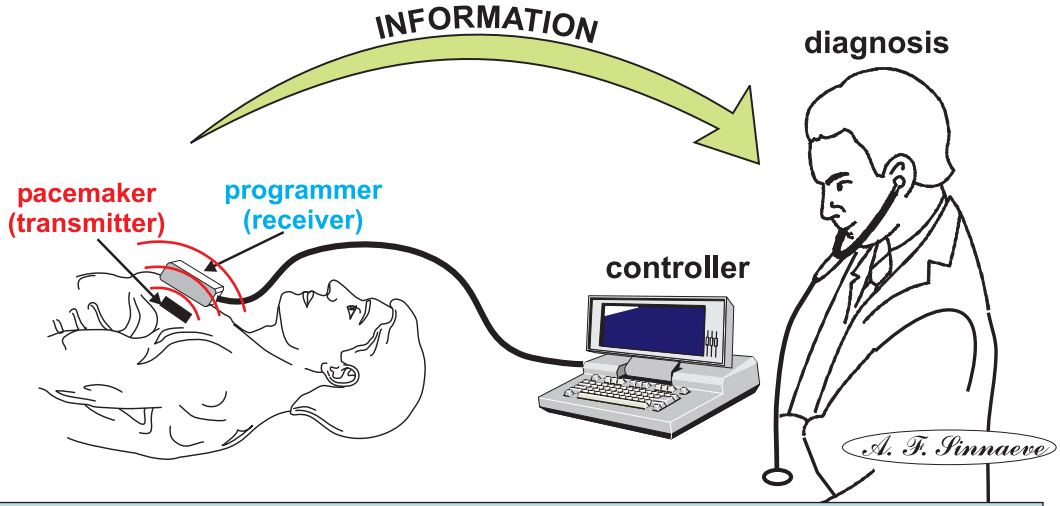


Pacemakers have many programmable functions that can be altered noninvasively with a special programmer. Unfortunately there is no universal programmer and each manufacturer provides programmers that will work only with their pacemakers

WARNING

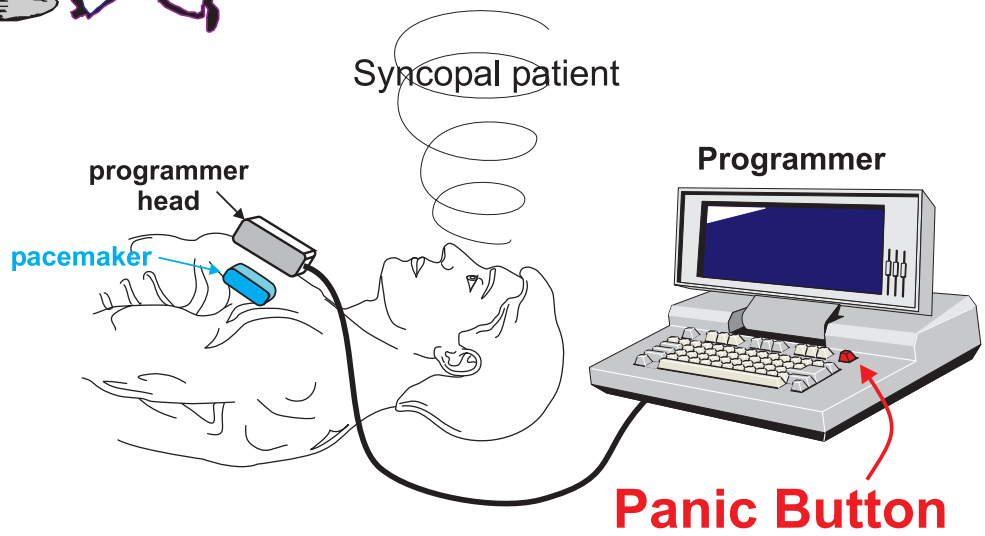
* Asystole can occur when programming the output. In an emergency use the panic button to restore pacing with a preset combination of parameters.
* Always have 2 programmers in case one malfunctions or breaks down

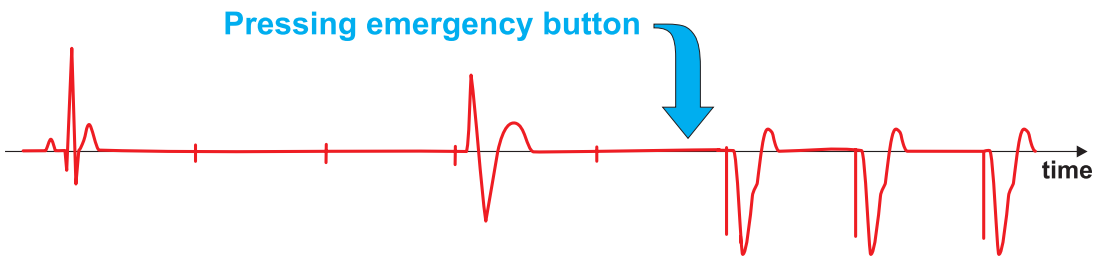
TELEMETRY : from pacemaker to controller



The stored parameters or instructions to the pacemaker can be retrieved by interrogation with a special programming head placed over the pacemaker. The data is then sent to the programmer which automatically delivers a printout. Parameters include rate, output (amplitude in volts and pulse duration in ms) and sensitivity.

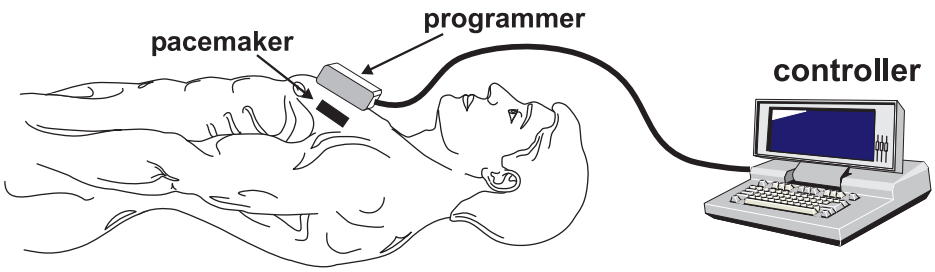
THE EMERGENCY BUTTON

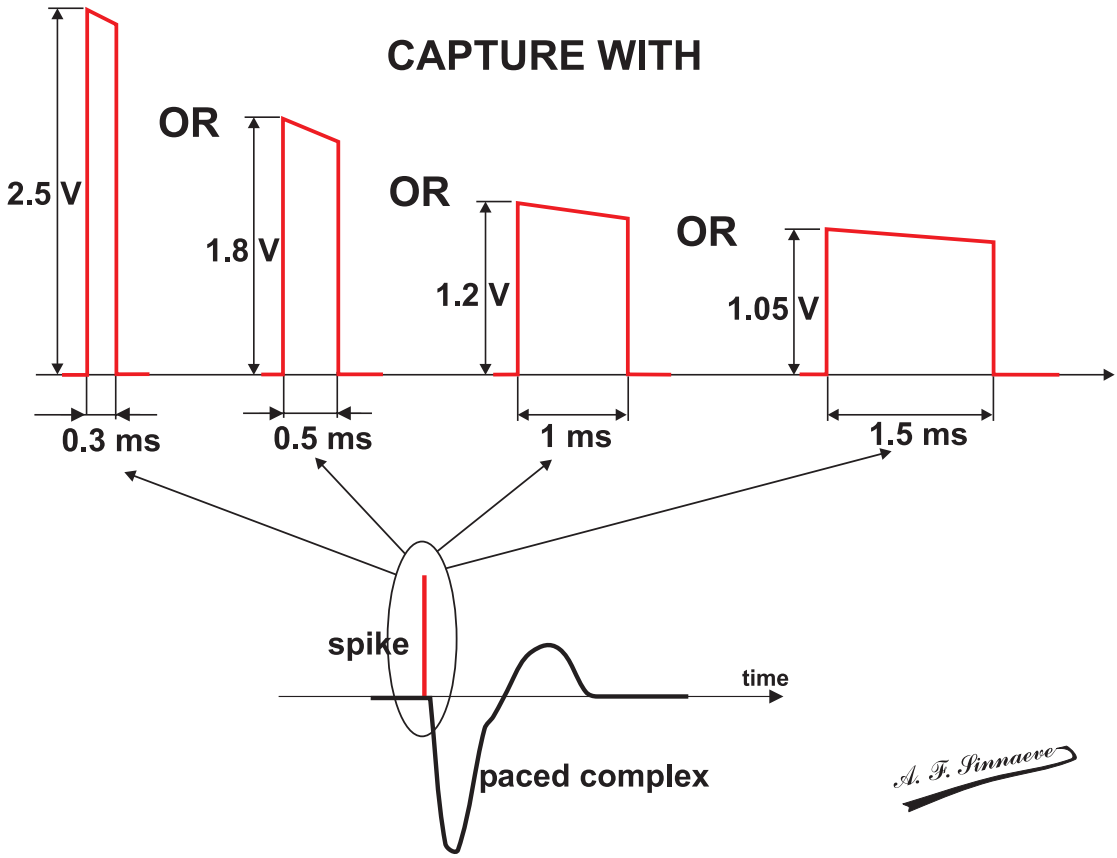




A. F. Sinnaeve

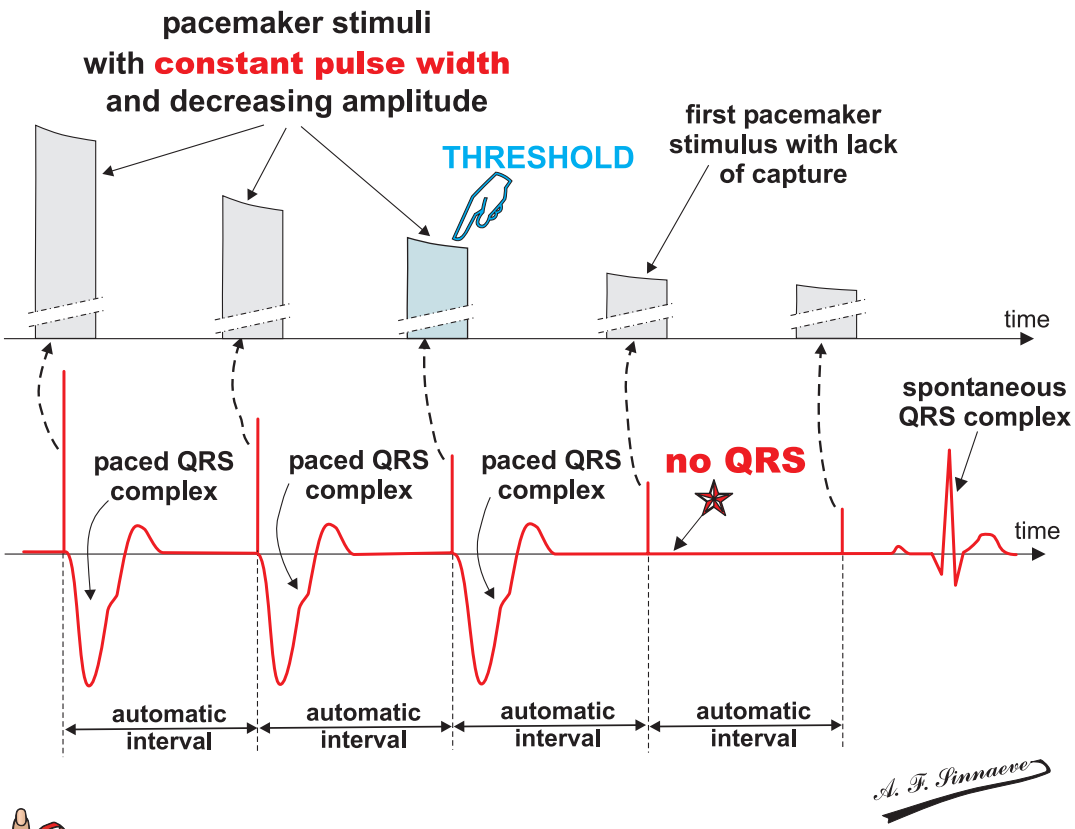
VOLTAGE AND PULSE DURATION MAY BE CHANGED BY AN EXTERNAL PROGRAMMER





A. F. Sinnaeve

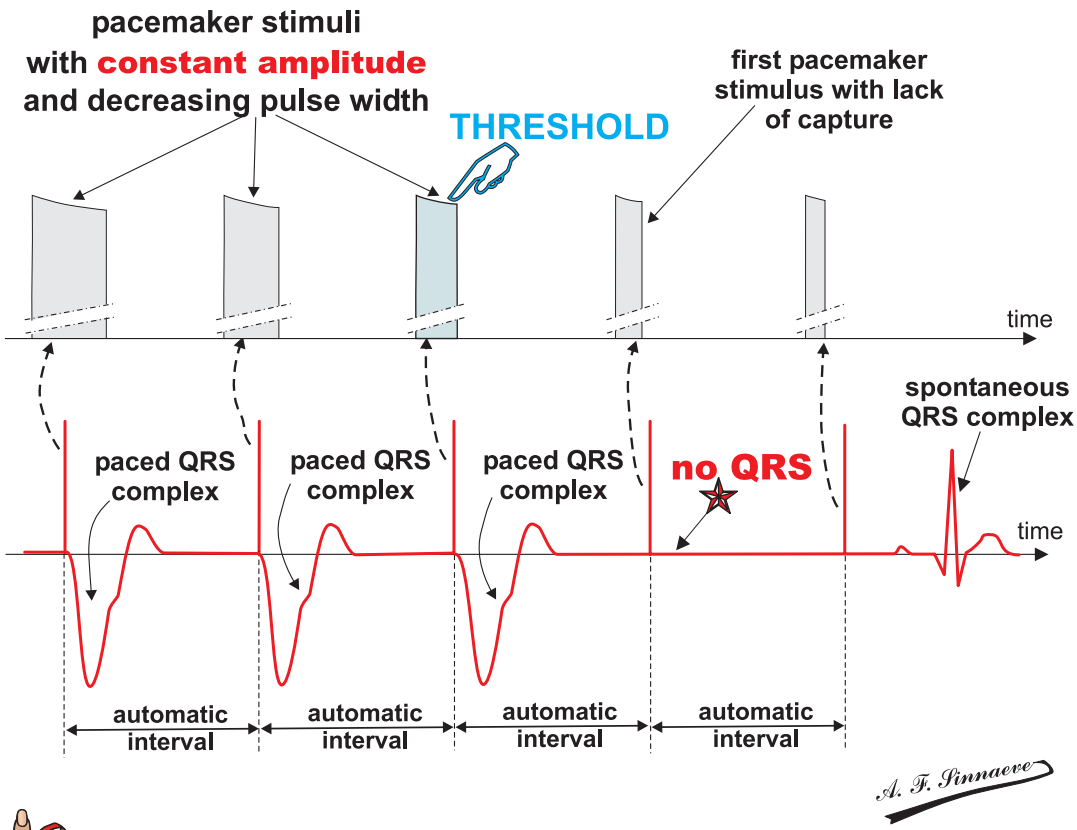
DETERMINATION OF PACING THRESHOLD



REMINDER

The pacing threshold is always expressed in terms of both voltage and pulse duration. The pacing threshold can be determined in terms of the smallest output voltage that captures the heart while keeping the pulse duration constant.

DETERMINATION OF PACING THRESHOLD



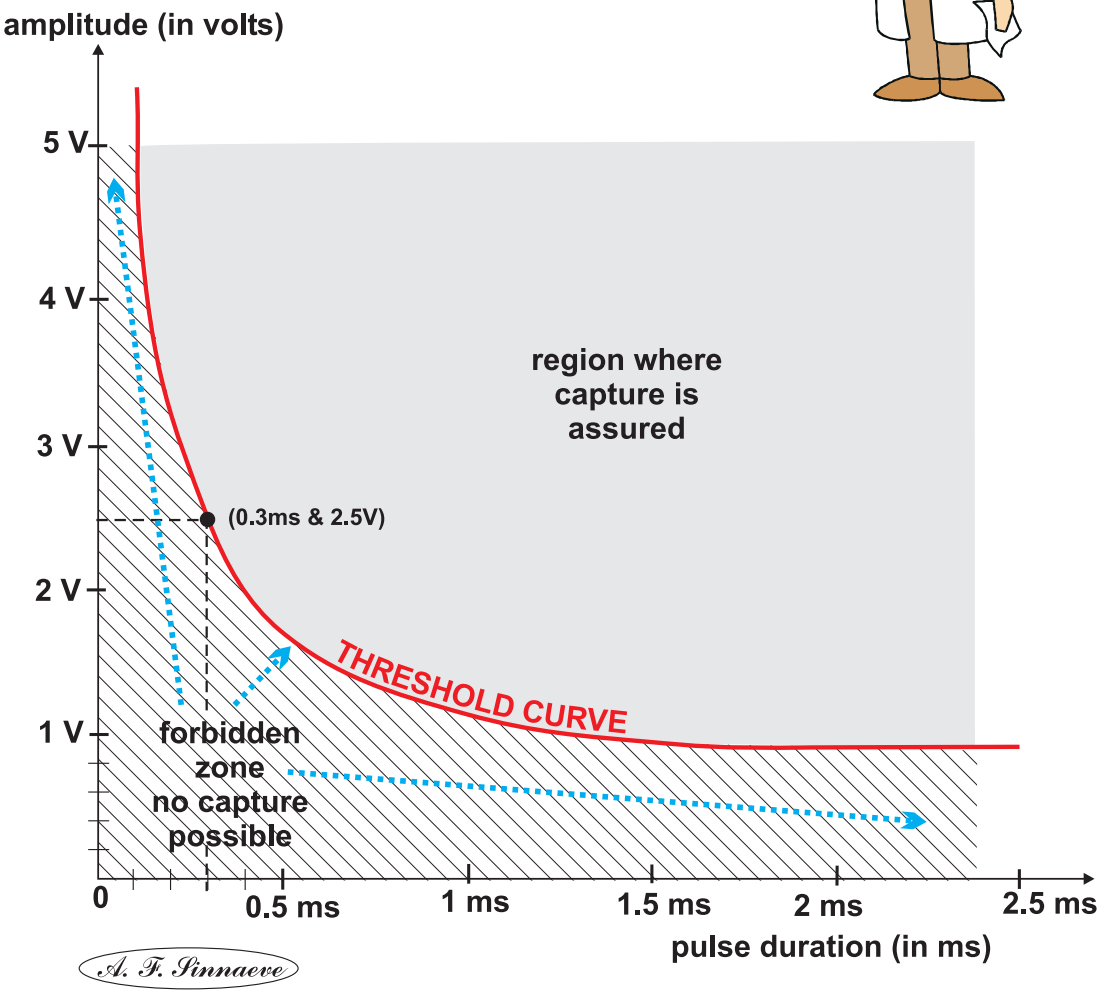
A. F. Sinnaeve

REMINDER

The pacing threshold is always expressed in terms of both voltage and pulse duration. The pacing threshold can be determined in terms of the shortest pulse duration that captures the heart while keeping the output voltage constant.

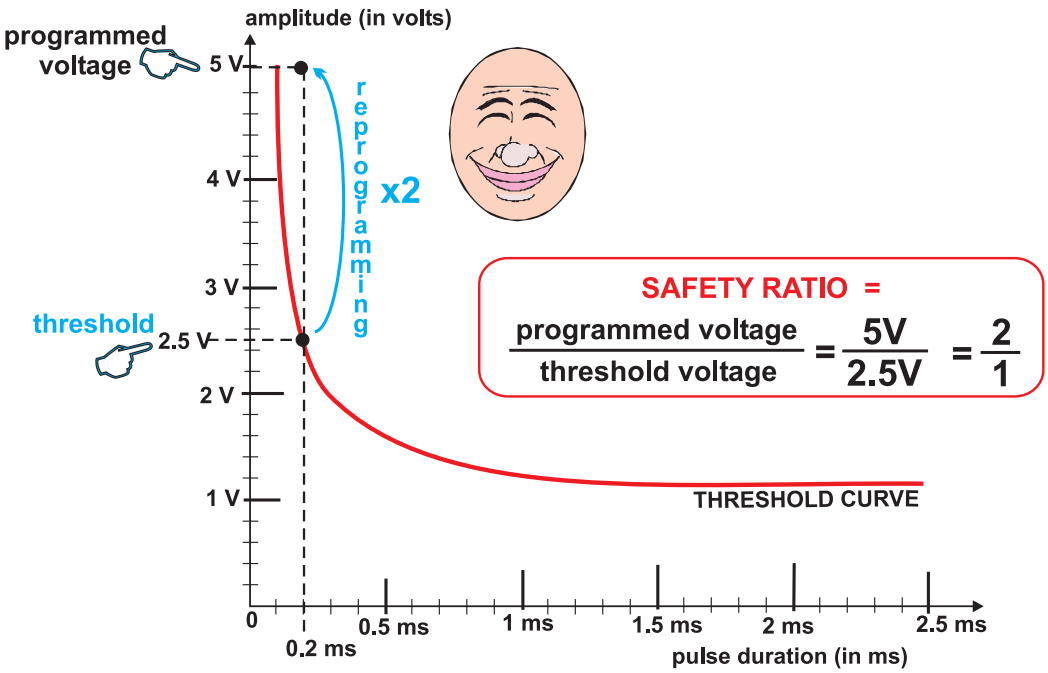
STRENGTH - DURATION CURVE

This is the most important law governing the whole field of electrostimulation !!!

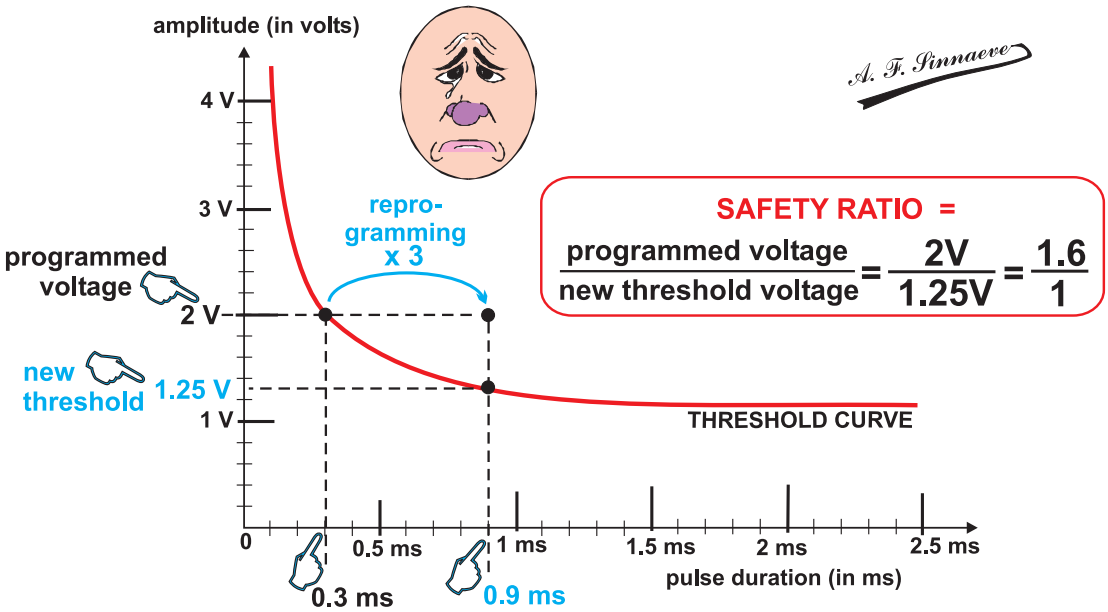


A. F. Sinnaeve

SAFETY RATIO CONCEPT FOR CAPTURE

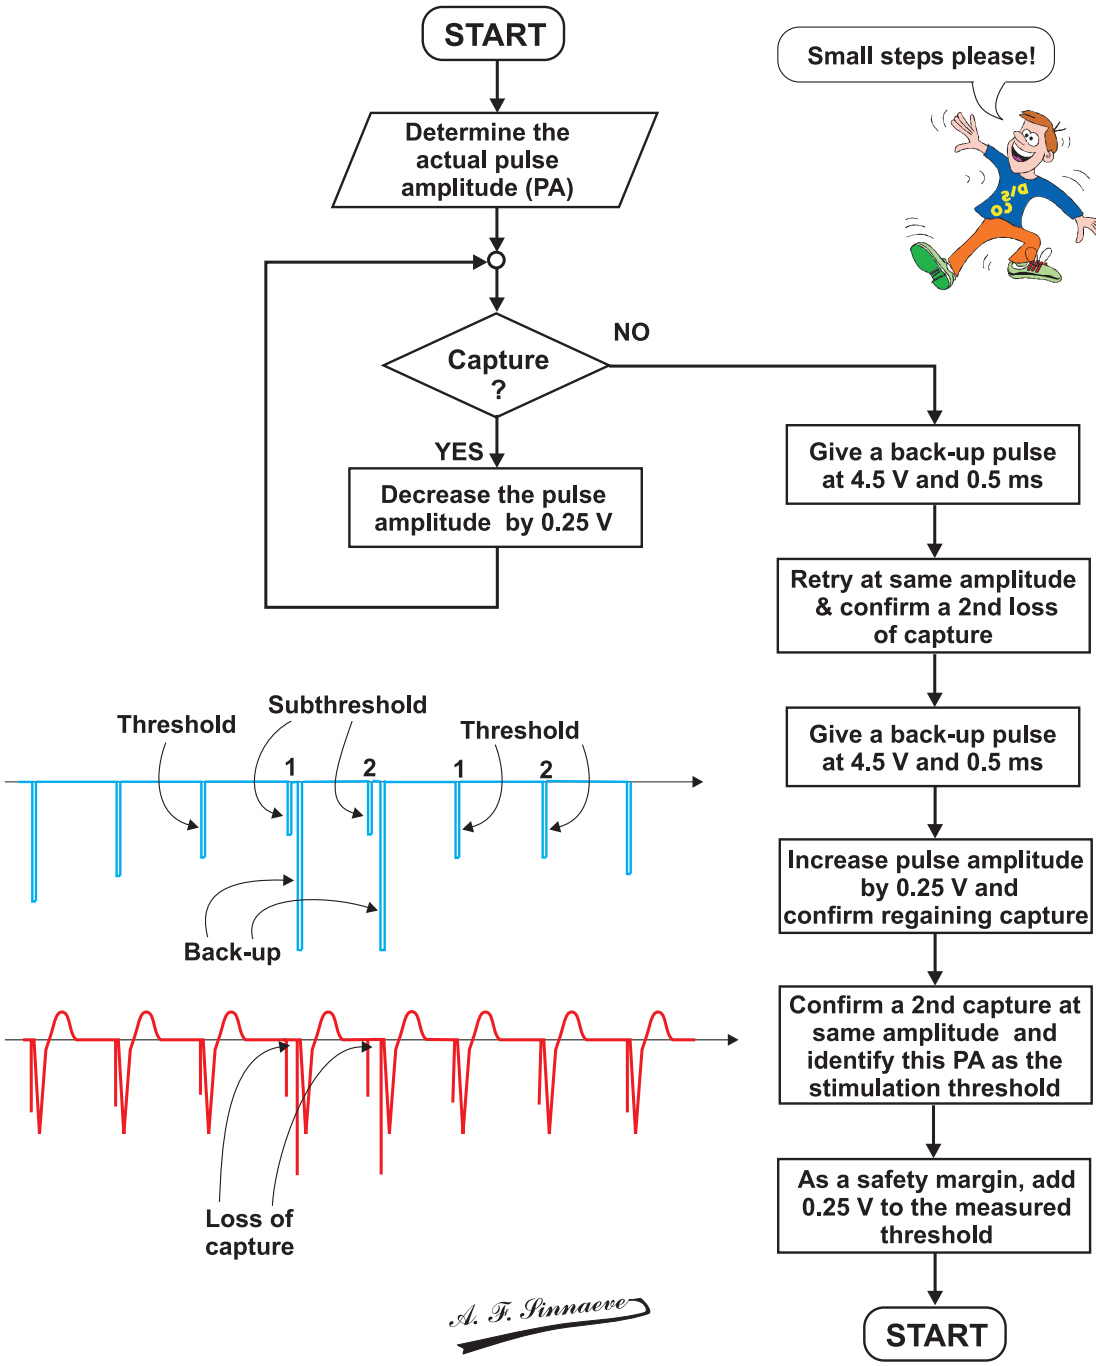


$$\text{SAFETY RATIO} = \frac{\text{programmed voltage}}{\text{threshold voltage}} = \frac{5V}{2.5V} = \frac{2}{1}$$

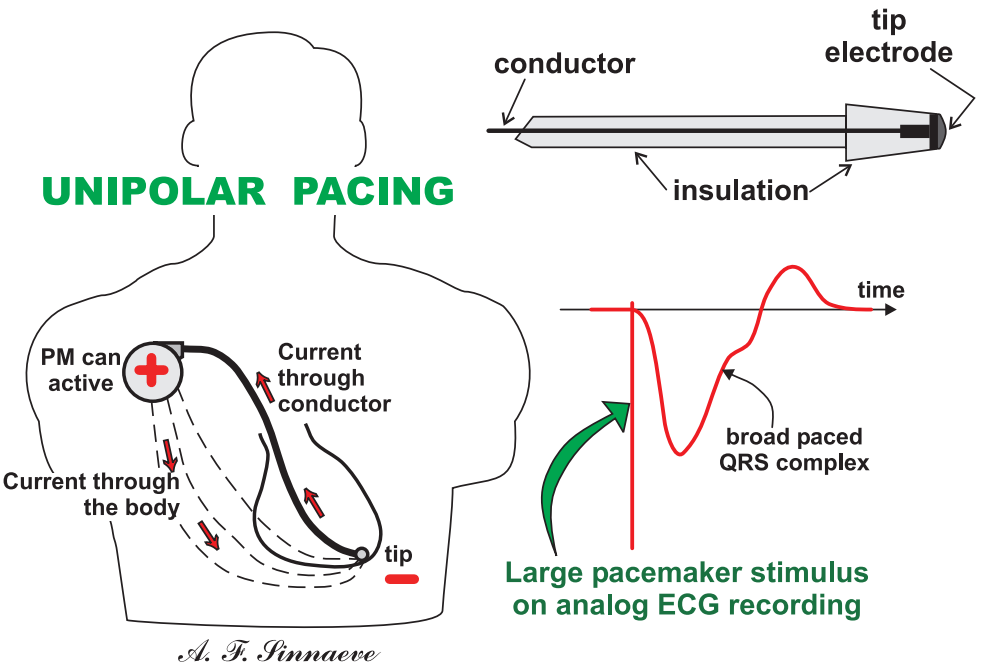


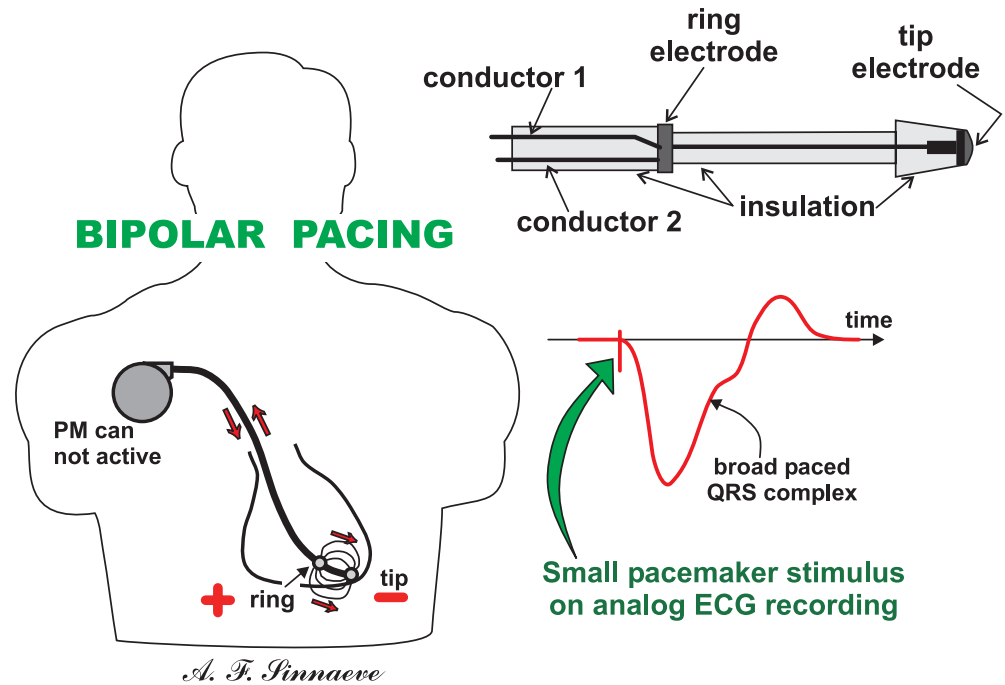
$$\text{SAFETY RATIO} = \frac{\text{programmed voltage}}{\text{new threshold voltage}} = \frac{2V}{1.25V} = \frac{1.6}{1}$$

AUTOMATIC STIMULATION THRESHOLD SEARCH



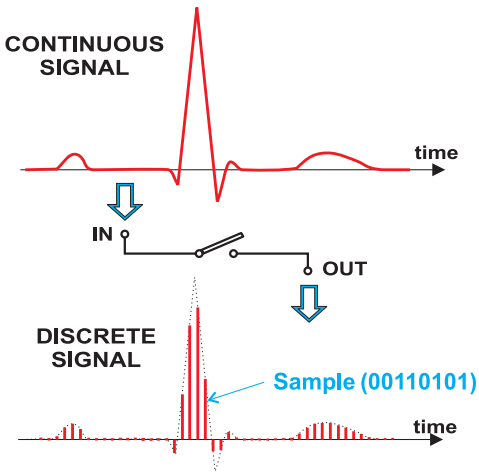
BIPOLAR vs UNIPOLAR PACING
SIZE OF THE STIMULUS ON ECG





VARIABILITY OF THE STIMULUS ARTIFACT ON A DIGITAL ELECTROCARDIOGRAPH

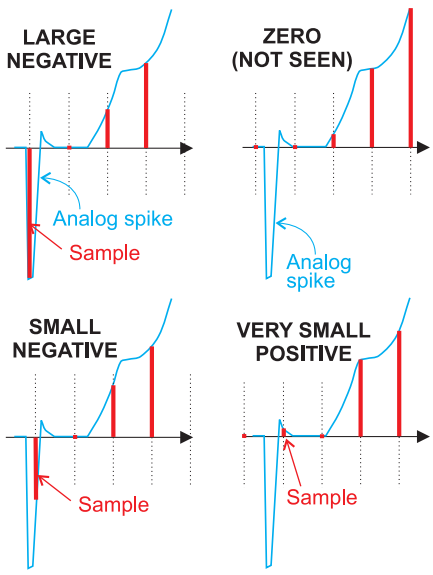
An analog recording system attempts to recreate the information as it actually happens. A digital ECG machine is not able to deal directly with continuously changing voltages, so the signals have to be prepared. A digital system takes the information and transforms it into a series of "samples". Consequently each sample is translated or "coded" in a binary number i.e. a series of zeros and ones called "bits".



SAMPLING A SIGNAL

Digital sampling is like sending the signal through a system with a very fast switch. The signal is measured repeatedly during a very brief instant by closing the switch.

Since the signal is only sampled at discrete points in time, some information may be missed when the sampling frequency is too low. In particular, sharp peaks and transitions in the slope of a signal are likely to be lost. The stimulus artifact or part of it can be easily missed by the sampling system with resultant varying amplitudes and direction of the pacemaker spike as it is recorded on the ECG.



The marked variation of the stimulus in amplitude and direction provided by a digital recorder may be confusing to the beginner who might wrongly assume there is pacemaker malfunction. What do you think ?

The diagnostic value of the pacemaker stimulus recorded by a digital recorder is zero ! Older analog recorders were more useful for that purpose

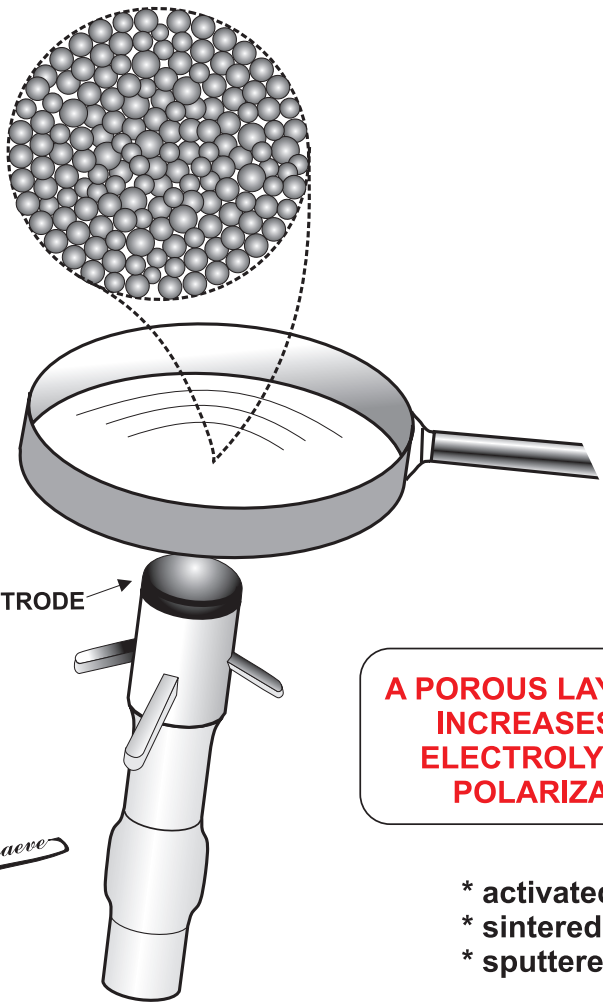
THE POROUS ELECTRODE

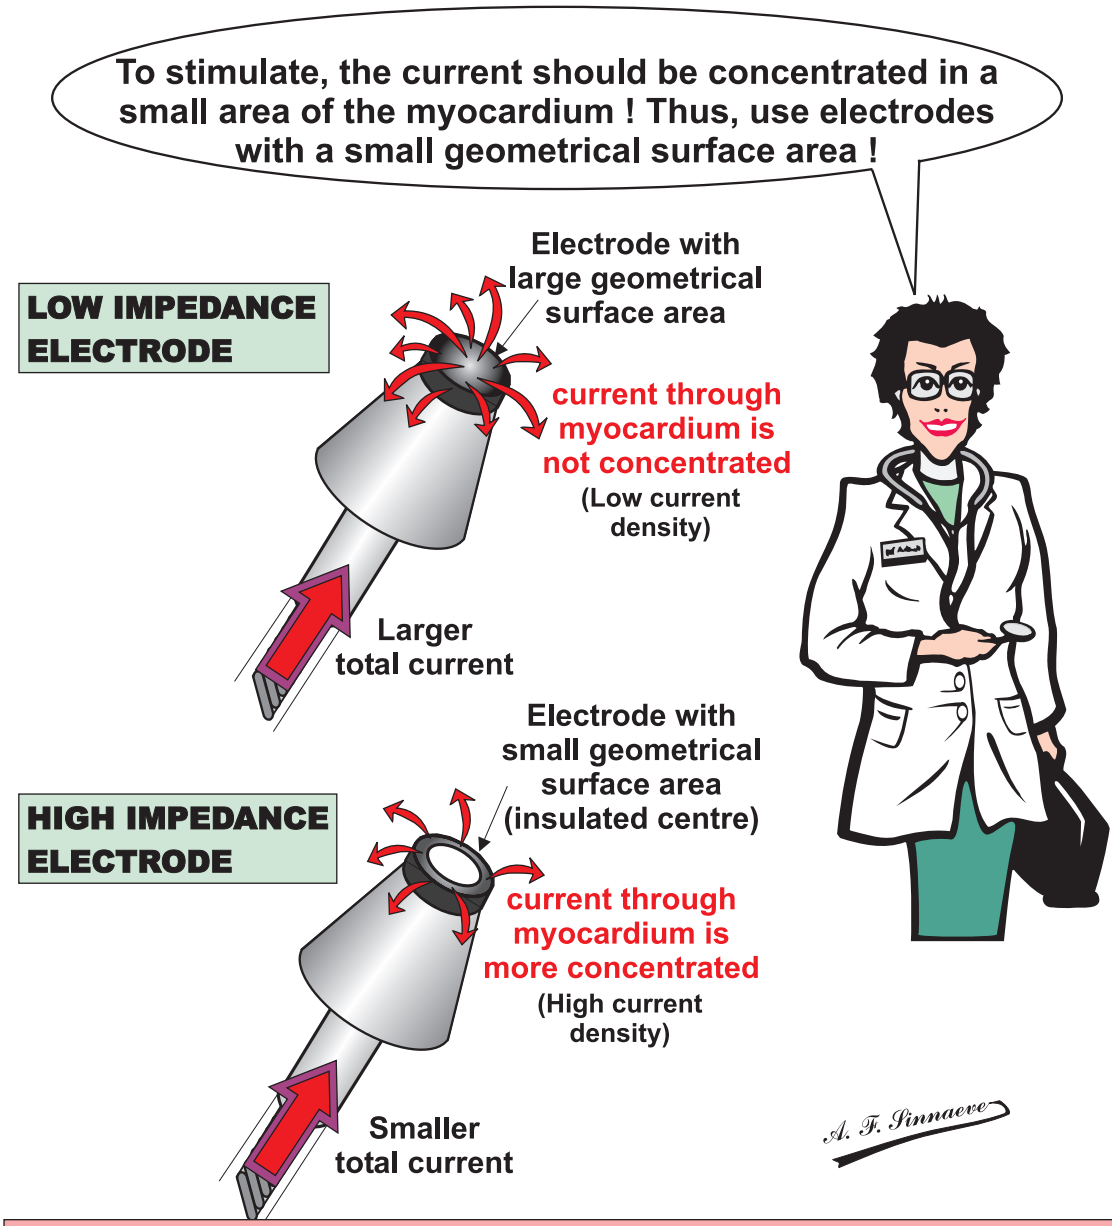
For good sensing,
the polarization voltage and the
afterpotential should be very low !
So, we use porous electrodes !



A POROUS LAYER ON THE ELECTRODE INCREASES CONTACT WITH THE ELECTROLYTE AND REDUCES THE POLARIZATION PHENOMENON

* activated carbon
* sintered platinum-iridium
* sputtered titanium-nitride

A. F. Sinnaeve



Reducing the geometric surface area of pacing electrodes increases the pacing impedance. Small area high impedance electrodes (>1000Ω) have become popular because their pacing thresholds are comparable or even better than those of conventional electrodes. A high impedance causes a decreased current drain from the battery as predicted by Ohm's law (I = U/R). The sensing characteristics of high impedance leads are similar to conventional ones. Thus, with the same performance as conventional leads, high impedance (better called high efficiency) leads significantly reduce current drain from the battery for stimulation and thereby increase battery longevity.

A. F. Sinnaeve

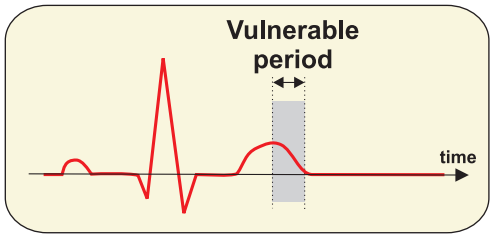
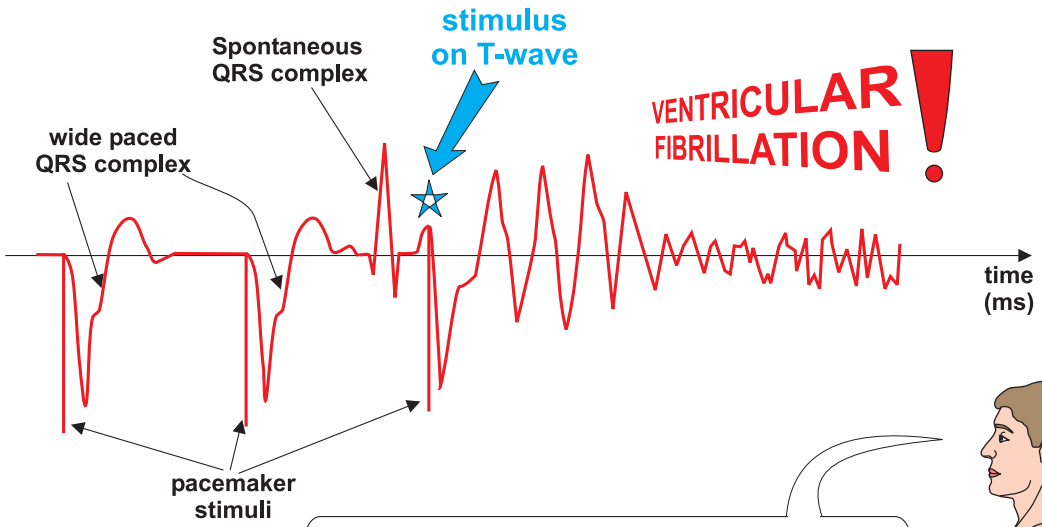
ASYNCHRONOUS PACING & STIMULUS ON T-WAVE

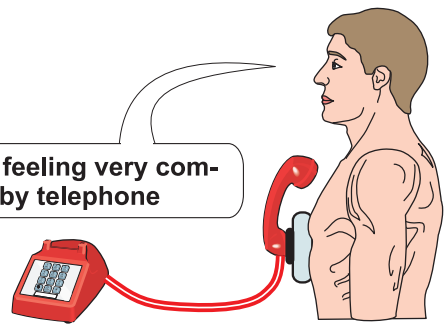
There must be a risk of firing a pacemaker stimulus into the ventricular vulnerable period !?



The risk is very small in the usual clinical situations. Countless patients transmit their ECG safely over the phone during follow-up when the magnet is placed over the pacemaker with the creation of a competitive ventricular rhythm and firing of the pacemaker on the T wave. The risk is confined to patients with serious metabolic (electrolyte) abnormalities or acute myocardial infarction or ischemia.



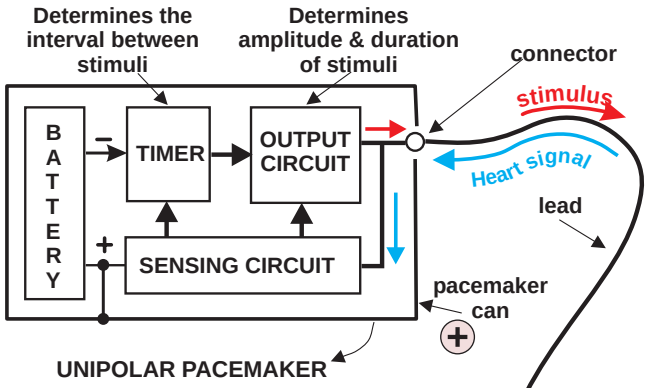
I'm not scared and I'm still feeling very comfortable with the follow-up by telephone

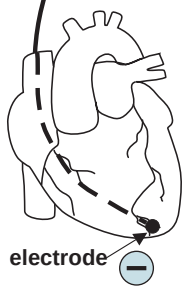


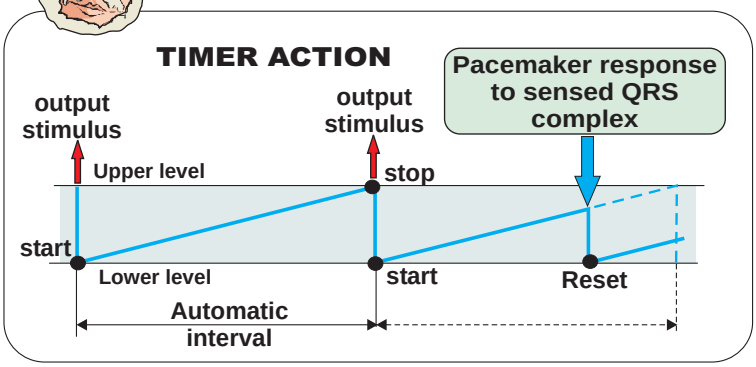
A. F. Sinnaeve

VENTRICULAR DEMAND PACING (VVI)

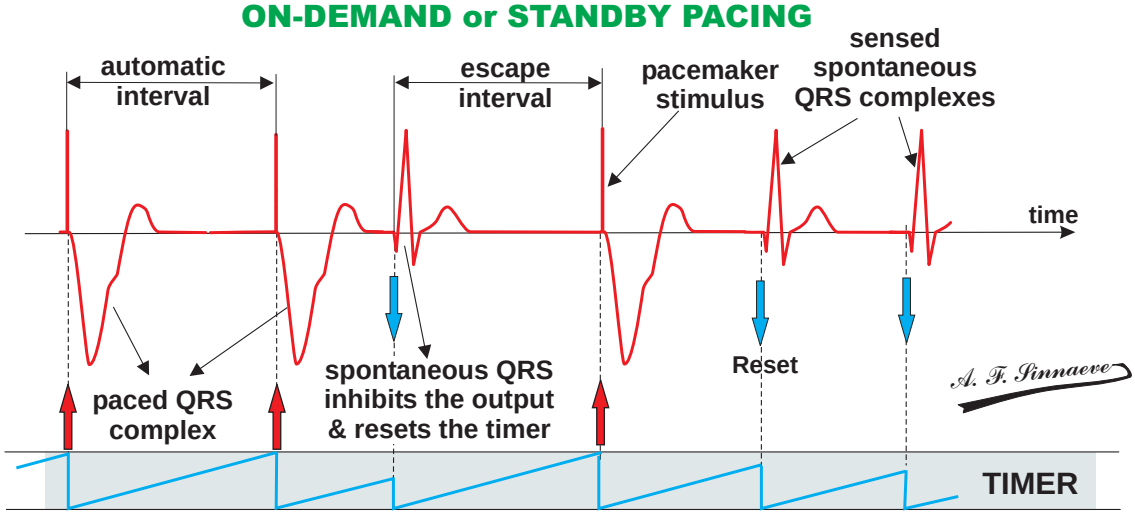
Note that in the VVI mode, a competitive rhythm is not possible. Moreover the lifetime of the battery is extended because the pacemaker is not pacing during long periods of time when it is on standby.







ON-DEMAND or STANDBY PACING

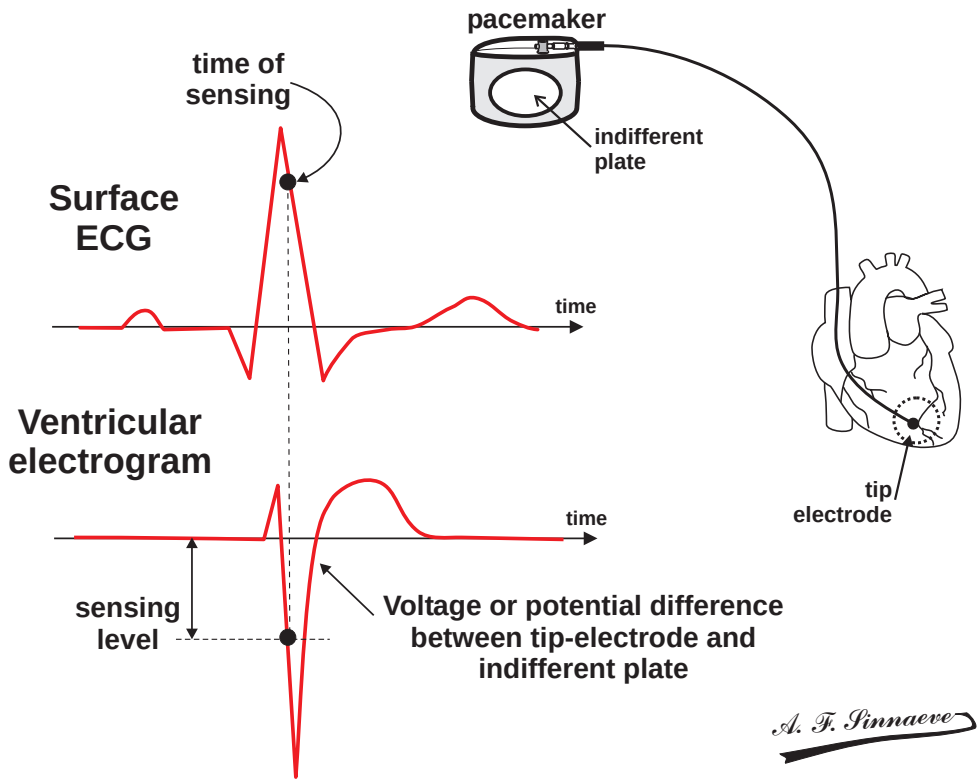


The electronic escape interval (starting at the time of intracardiac sensing) is equal to the automatic interval. The escape interval is measured on the surface ECG from the onset of the QRS complex because the time of intracardiac sensing cannot be determined accurately. Therefore the escape interval so measured will be slightly longer than the automatic interval because intracardiac sensing occurs later than the beginning of the surface QRS complex.

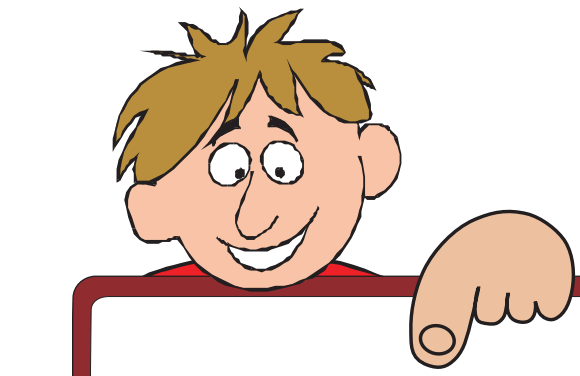
WHAT DOES THE PACEMAKER SENSE ?

How does a demand pacemaker know when to deliver a stimulus ? Does it recognize the ECG ?

The pacemaker does not sense the surface ECG nor the ECG near the pacemaker can. It detects what is going on inside the heart itself by measuring the potential difference (voltage) between the two electrodes used for pacing. The voltage of intracardiac depolarization is larger than that of the surface ECG and is called an electrogram rather than electrocardiogram.
Therefore, the time of electronic sensing the intracardiac electrogram does not correspond with the onset of the surface ECG because it takes a finite time for the activation to reach the electrodes (for example in the right ventricle) and generate the electrogram



A. F. Sinnaeve



MARKERS & SYMBOLS
ACCORDING TO MANUFACTURERS

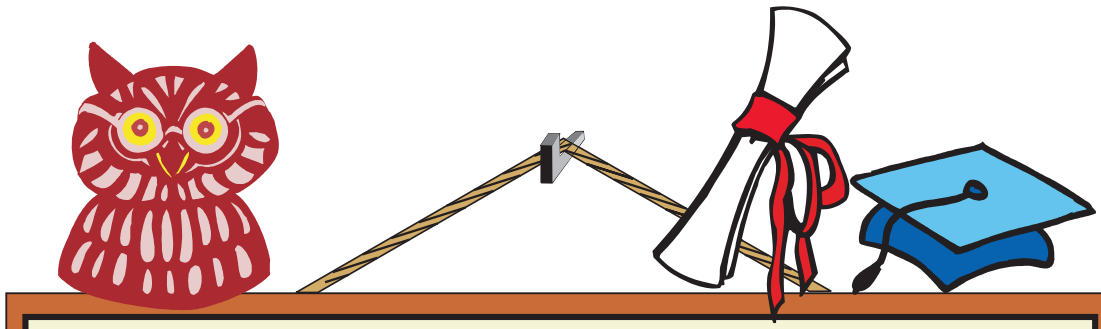
V = ventricular pace
R = ventricular sense (R wave)
R = ventricular sense in refractory period

A. F. Sinnaeve



THREE-LETTER PACEMAKER CODE (ICHD)

POSITION	1st	2nd	3rd
CATEGORY	CHAMBER(S) PACED	CHAMBER(S) SENSED	MODE OF RESPONSE
LETTERS	V = VENTRICLE A = ATRIUM S = SINGLE	V = VENTRICLE A = ATRIUM S = SINGLE O = NONE	T = TRIGGERED I = INHIBITED O = NONE

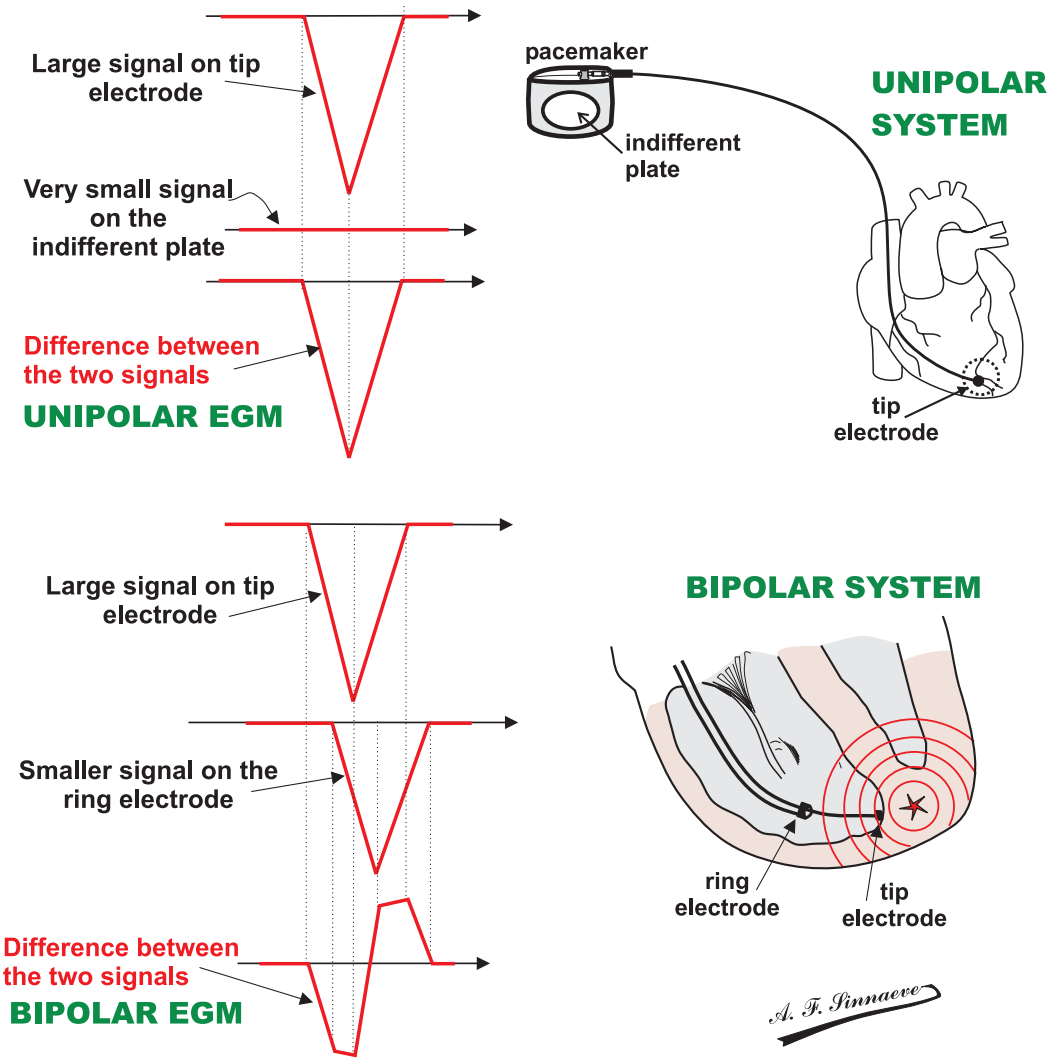
EXAMPLES :

AAI = a pacemaker pacing and sensing in the atrium, being inhibited by spontaneous electrical activation of the atrium

VVT = a pacemaker pacing and sensing in the ventricle and working in the triggered mode (each sensed ventricular event elicits a pacemaker stimulus)

A. F. Sinnaeve

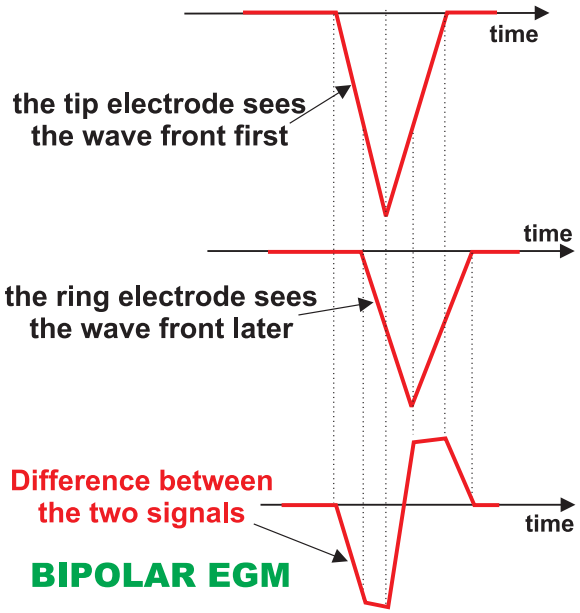
THE SENSING AMPLIFIER MEASURES THE DIFFERENCE BETWEEN TWO SIGNALS AT THE PACING ELECTRODES



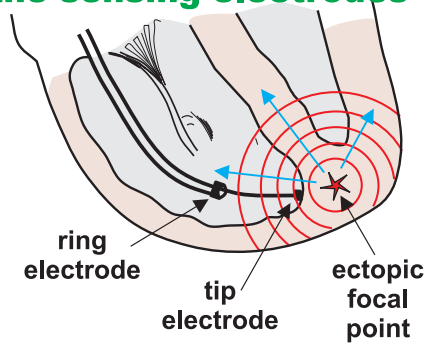
Note that on each instant of time, the bipolar electrogram (EGM) is the difference between the EGMs recorded at the tip and ring electrodes. The EGMs arrive at different times and this timing or phase difference generates the bipolar EGM.

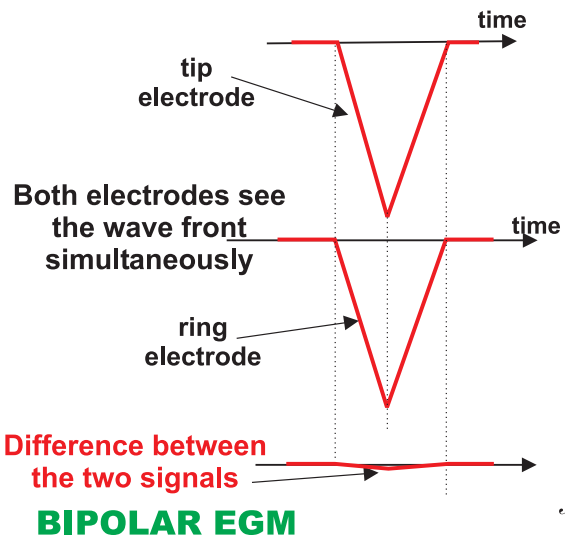
VARIABILITY OF BIPOLAR SENSING

* The sensed signal to the pacemaker is the voltage or potential difference between the two intracardiac electrodes
* The bipolar EGM depends on both the amplitude and timing (phase difference) of the electrograms registered at each of the two intracardiac electrodes

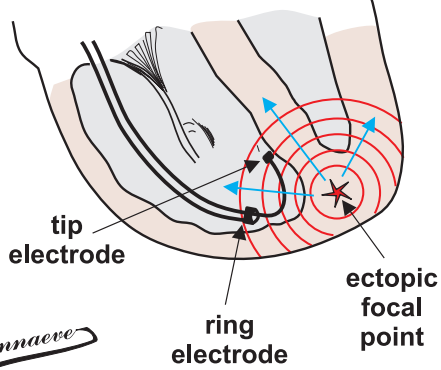


Wave front advancing parallel to the axis of the sensing electrodes





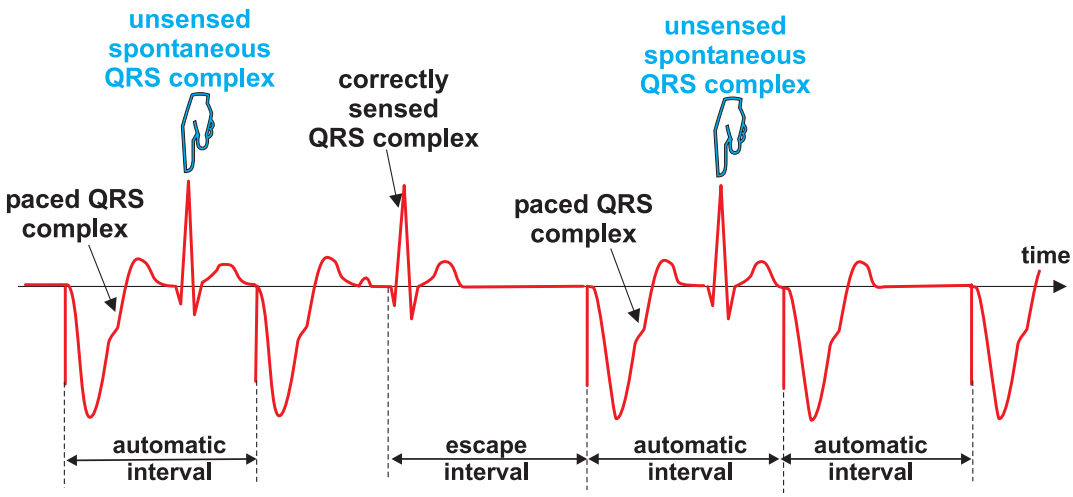
Wave front advancing perpendicular to the axis of the sensing electrodes



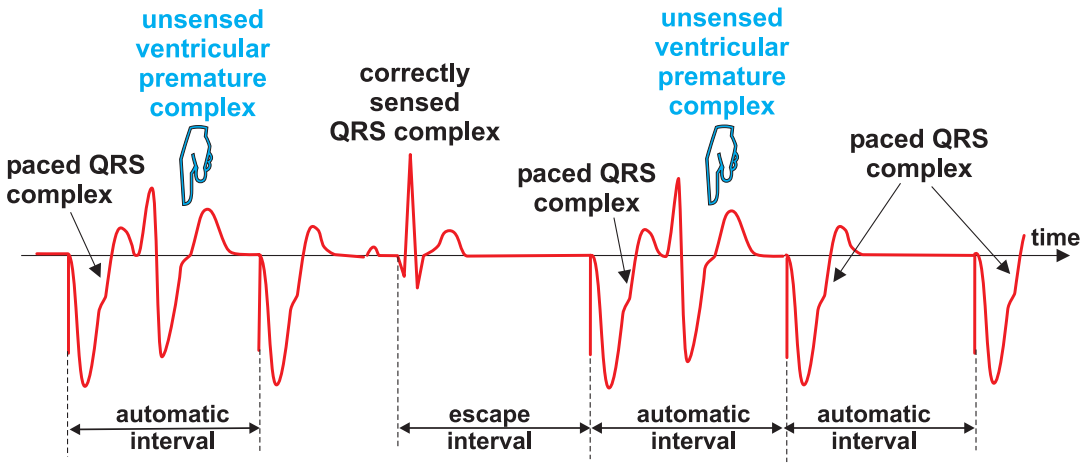
A. F. Sinnaeve

Identical signals arriving exactly at the same time at the two electrodes will yield a zero bipolar electrogram (EGM). Although this is theoretical, it is possible for two large unipolar EGMs to generate a relatively small bipolar EGM. In this situation, if there is undersensing, the bipolar sensing mode can be reprogrammed to the unipolar sensing mode.

1 INTERMITTENT UNDERSENSING OF A DEMAND PACEMAKER

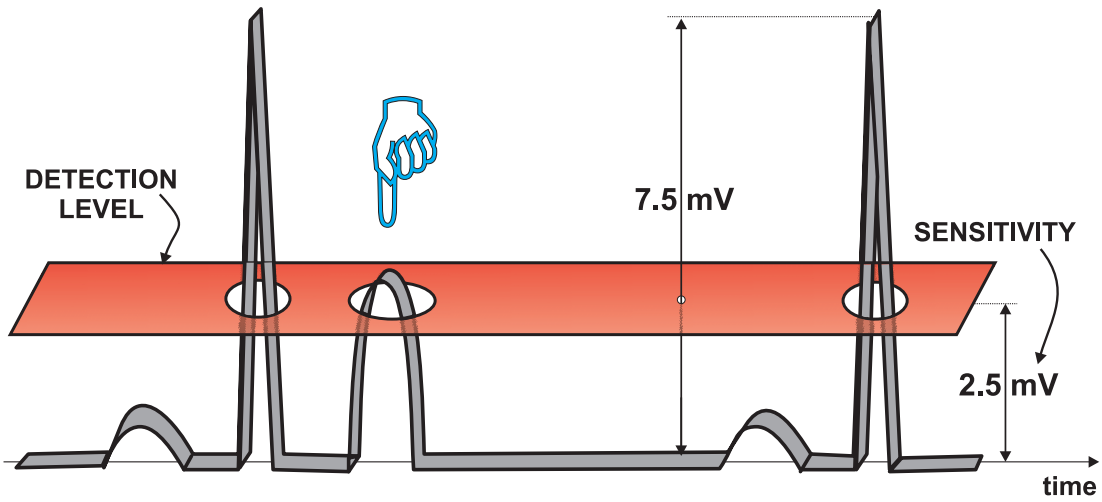


2 UNDERSENSING OF VPC BY DEMAND PACEMAKER

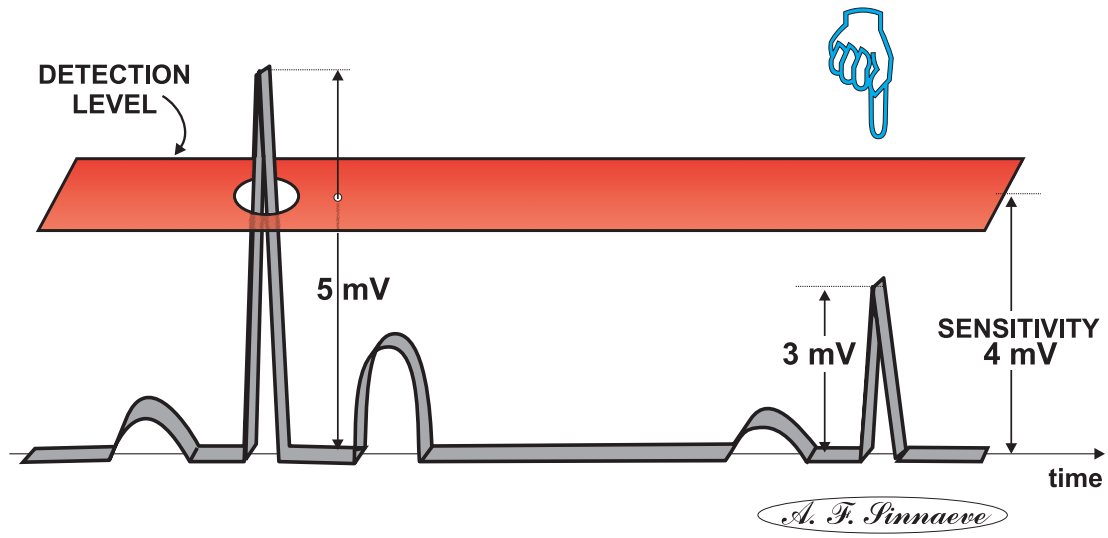


A. F. Sinnaeve

OVERSENSING



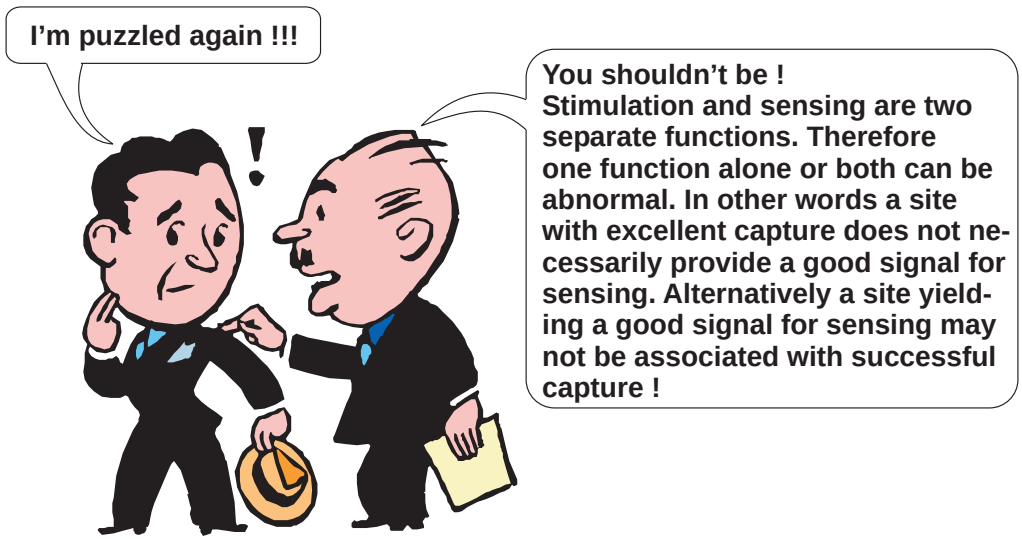
UNDERSENSING

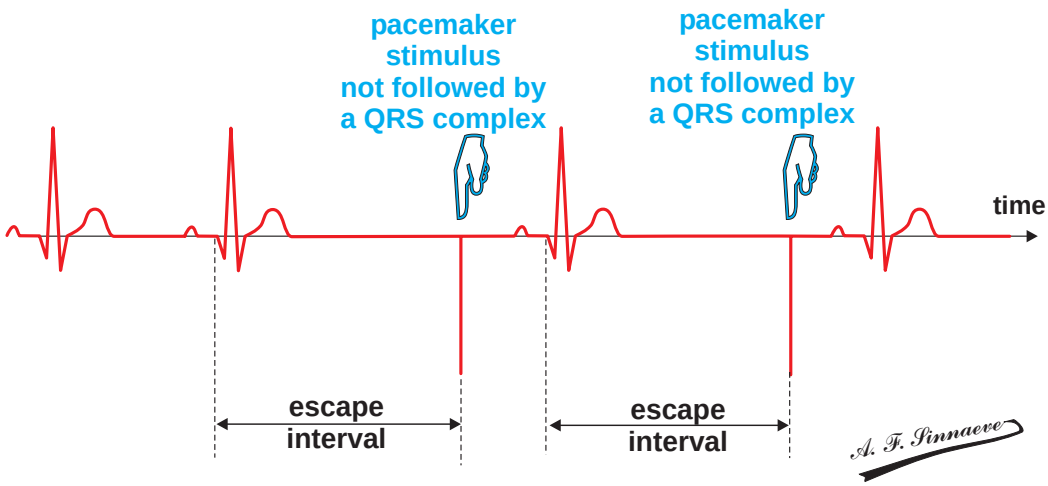


A. F. Sinnaeve

The voltage refers to the intracardiac electrogram and not the surface QRS complex. Sensitivity refers to a programmable parameter of the pacemaker. A sensitivity of 4 mV means that the pacemaker can only sense a signal equal to or greater than 4 mV. It will sense a signal of 5 mV but not a signal of 3 mV.

LACK OF VENTRICULAR CAPTURE OF A DEMAND PACEMAKER WITH NORMAL SENSING

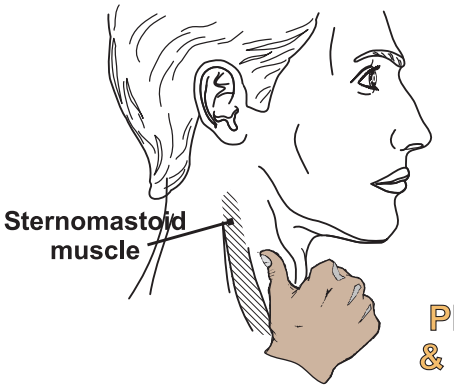




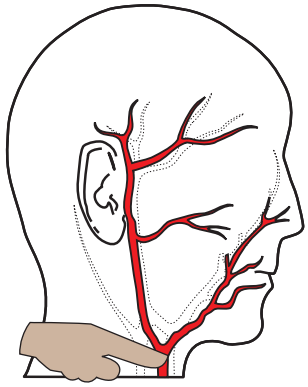
WARNING

Capture and sensing must be tested separately

CAROTID SINUS MASSAGE

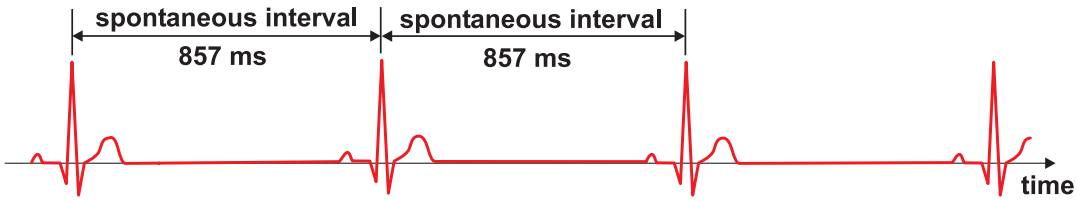


PRESSURE
& MASSAGE

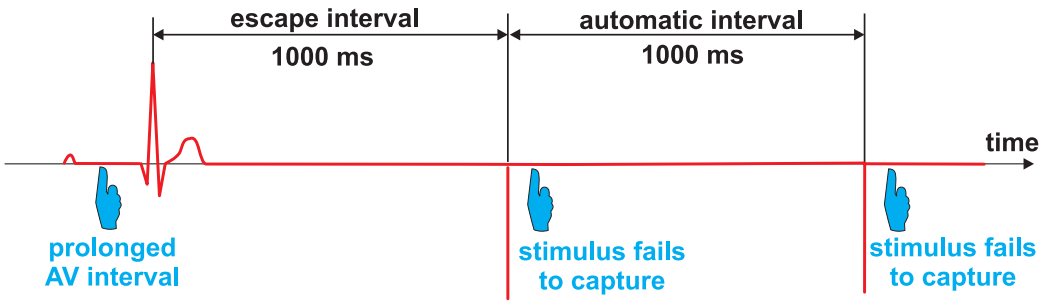


A. F. Sinnaeve

Without massage



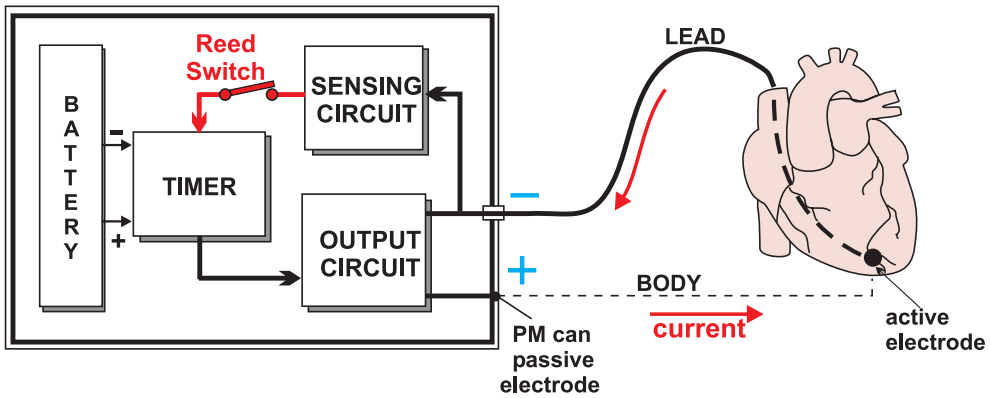
During massage (CSP =carotid sinus pressure)

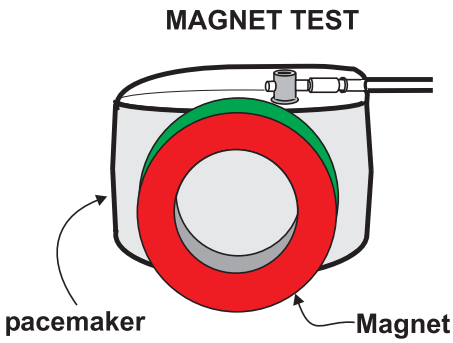


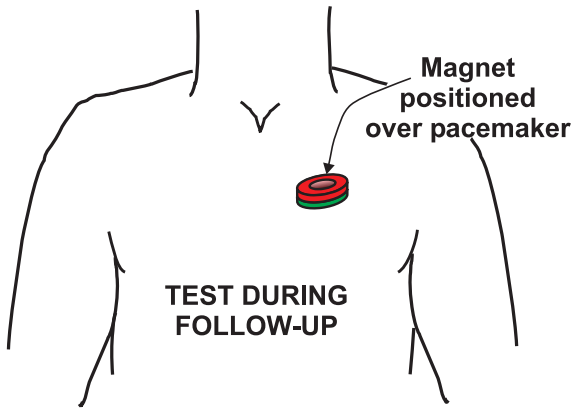
WARNING !!!

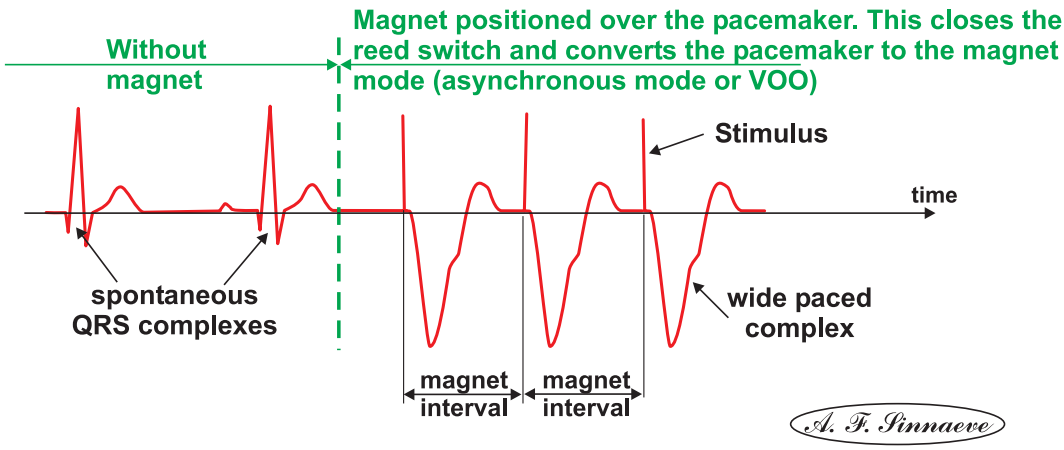
When a patient presents with an ECG showing no pacemaker stimuli, do not perform carotid sinus massage to test the pacemaker because it may cause prolonged bradycardia. The pacemaker will then deliver its stimuli that may or may not capture the heart. The pacing function should be tested first by the application of a pacemaker magnet, which converts any pacemaker to the fixed-rate or asynchronous mode (VVI to VOO).

MAGNET APPLICATION ON A DEMAND PACEMAKER







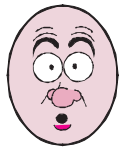


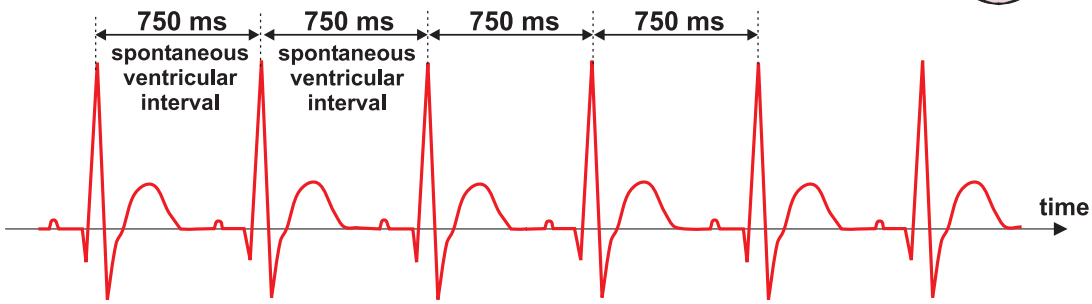
A. F. Sinnaeve

DOES THE PACEMAKER FUNCTION ?

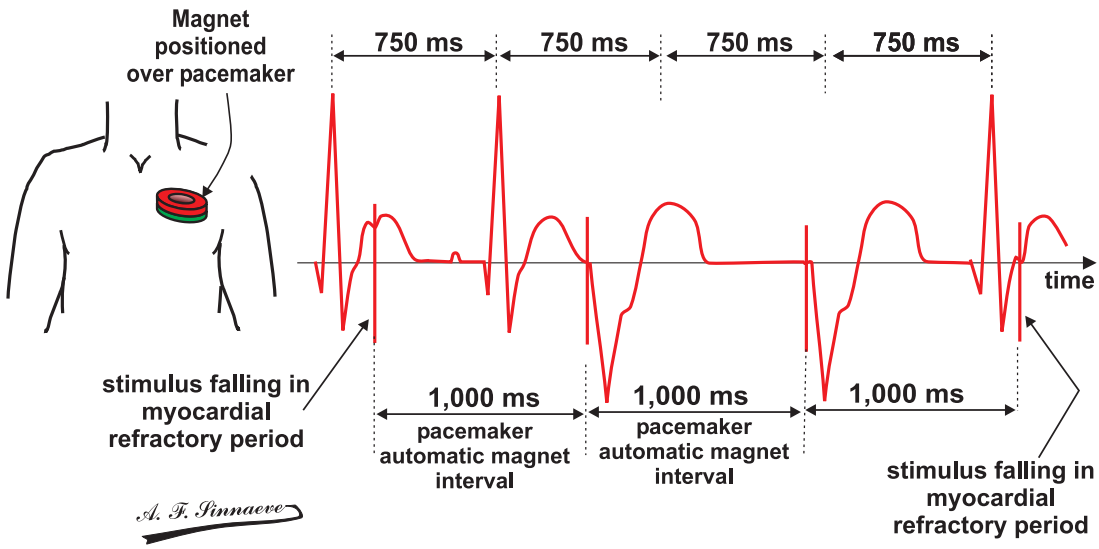
Spontaneous rhythm of the patient 80 bpm (beats per minute)

(or spontaneous R-R interval = $\frac{60{,}000}{80}$ = 750 ms)



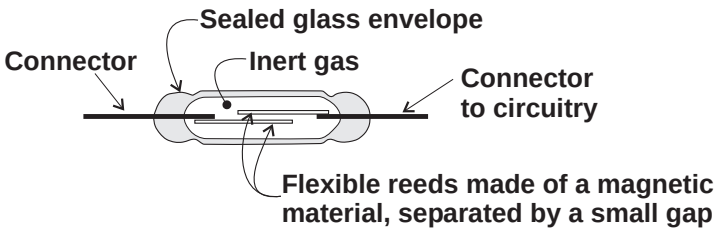


After magnet application, showing the pacemaker programmed at 60 bpm (or an automatic interval = $\frac{60{,}000}{100}$ = 1,000 ms also equal to the magnet interval of this pacemaker)

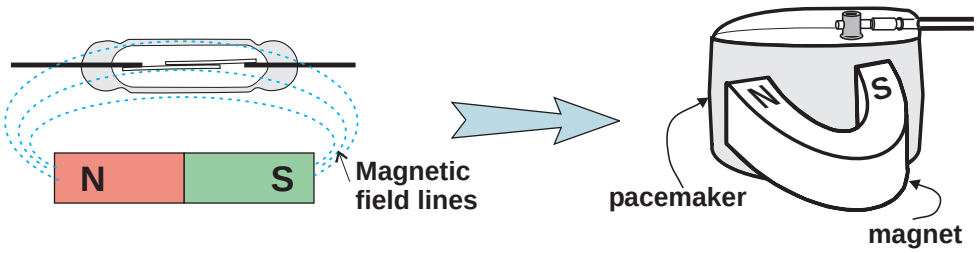


THE MAGNETIC REED SWITCH

NORMAL REED SWITCH
OPEN CONTACT WITHOUT MAGNETIC FIELD



NORMAL REED SWITCH
CLOSED CONTACT WITH MAGNETIC FIELD



A MAGNET AND A REED SWITCH ARE NEEDED FOR TESTING

* Magnet mode forces the pacemaker's programmed operation to an asynchronous mode (DOO in dual chamber devices and VOO/AOO in single chamber devices)
* The programming system of many pacemakers requires preliminary closure of the reed switch before the command is transmitted from the programmer to the pacemaker; in such a case the programming head contains an appropriate magnet for this purpose.

THE MAGNET IS UNABLE TO CLOSE THE REED SWITCH IF

° the magnet is not properly positioned (wrong site)
° the distance between magnet and reed switch may be too large in obese patients
° the magnet is too weak (try 2 or 3 toroid magnets on top of each other)
° the magnet function is programmed OFF

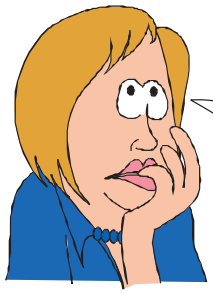
TRUE MALFUNCTION OF THE REED SWITCH IS VERY RARE

* Failure to close : the pacemaker cannot be converted to the magnet mode
* The "sticky" reed switch stays permanently closed with persistent asynchronous pacing

Caution : as a rule, application of a magnet on an ICD, deactivates tachycardia therapy but not its pacing and sensing function for bradycardia therapy.

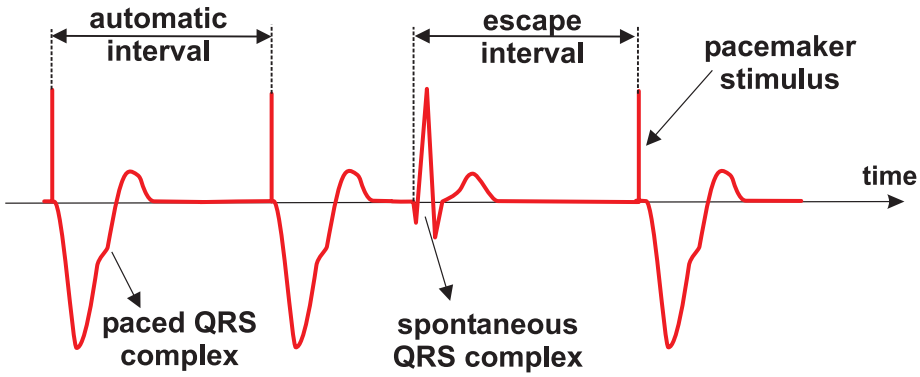
A. F. Sinnaeve

HYSTERESIS 1

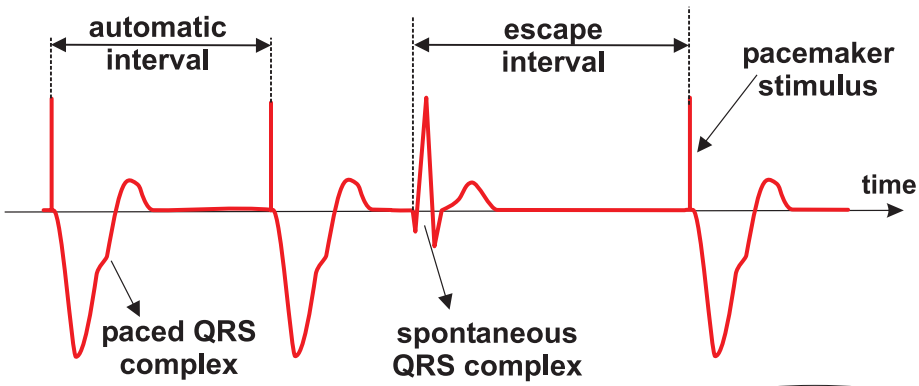


This isn't looking very easy to me !
And the interval between two ventricular events can be longer than the basic or automatic interval ?

WITHOUT HYSTERESIS
the automatic interval equals the escape interval



WITH HYSTERESIS
the escape interval is longer than the automatic interval



A. F. Sinnaeve

HYSTERESIS 2

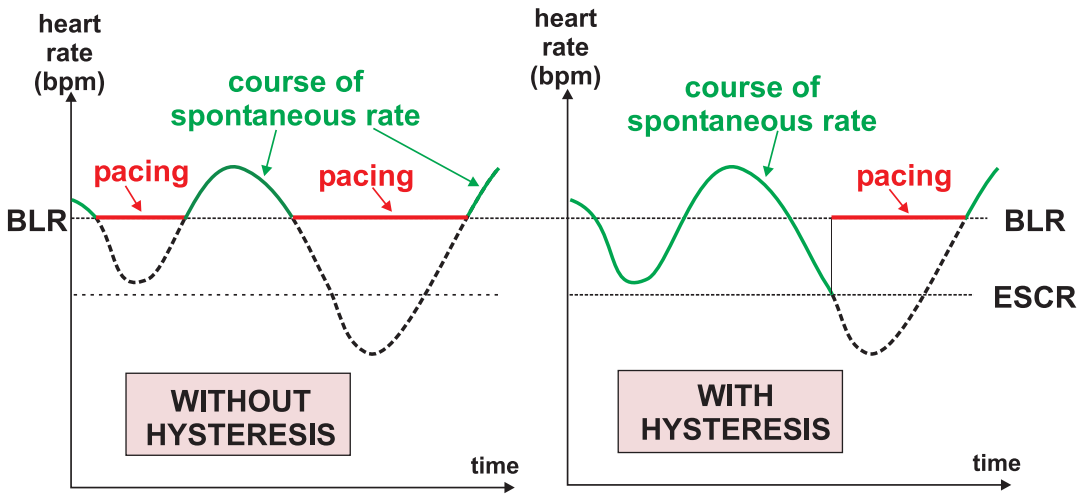
Hysteresis has some fine advantages :
* the spontaneous AV synchrony can be maintained as long as possible
* it prevents symptomatic retrograde VA conduction
* allowing a lower rate increases the longevity of the battery

LRI = basic lower rate interval = automatic interval (in ms)

ESCI = escape interval (in ms)

BLR = basic lower rate = $\frac{60\ 000}{LRI}$ (in bpm)

ESCR = escape rate = $\frac{60\ 000}{ESCI}$ (in bpm)



A. F. Sinnaeve

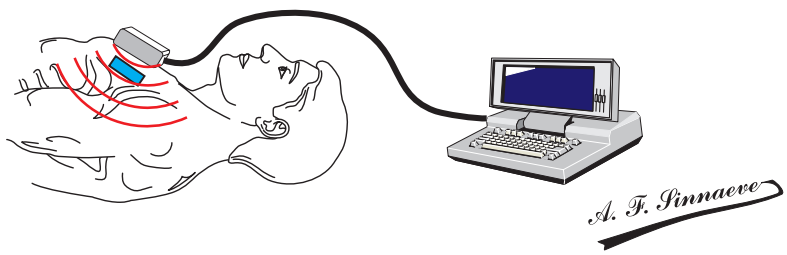
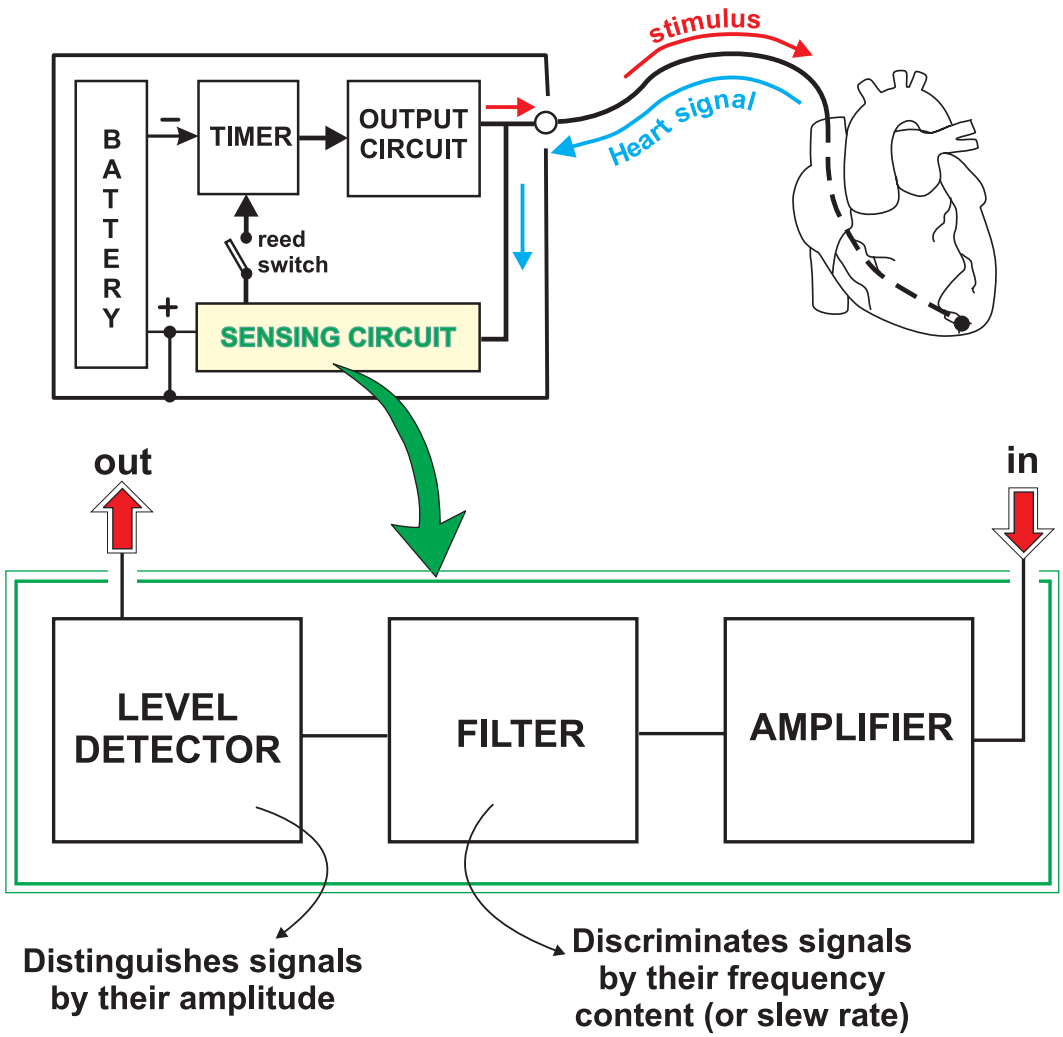
* Functions of VRP
* The pacemaker VRP
* The blanking period
* Programming lower sensitivity
* Programming higher sensitivity
* Sensing threshold - nonautomatic determination
* Electrographic (EGM) signal recording with ECG machine



THE SENSING FUNCTION



"Amplifier" and "Level Detector" determine the SENSITIVITY expressed in millivolts

* high sensitivity is characterized by a small number of mV (i.e. the sensing circuit already reacts on small signals)
* low sensitivity is expressed by a large number of mV (i.e. the sensing circuit only reacts upon large signals)

A. F. Sinnaeve

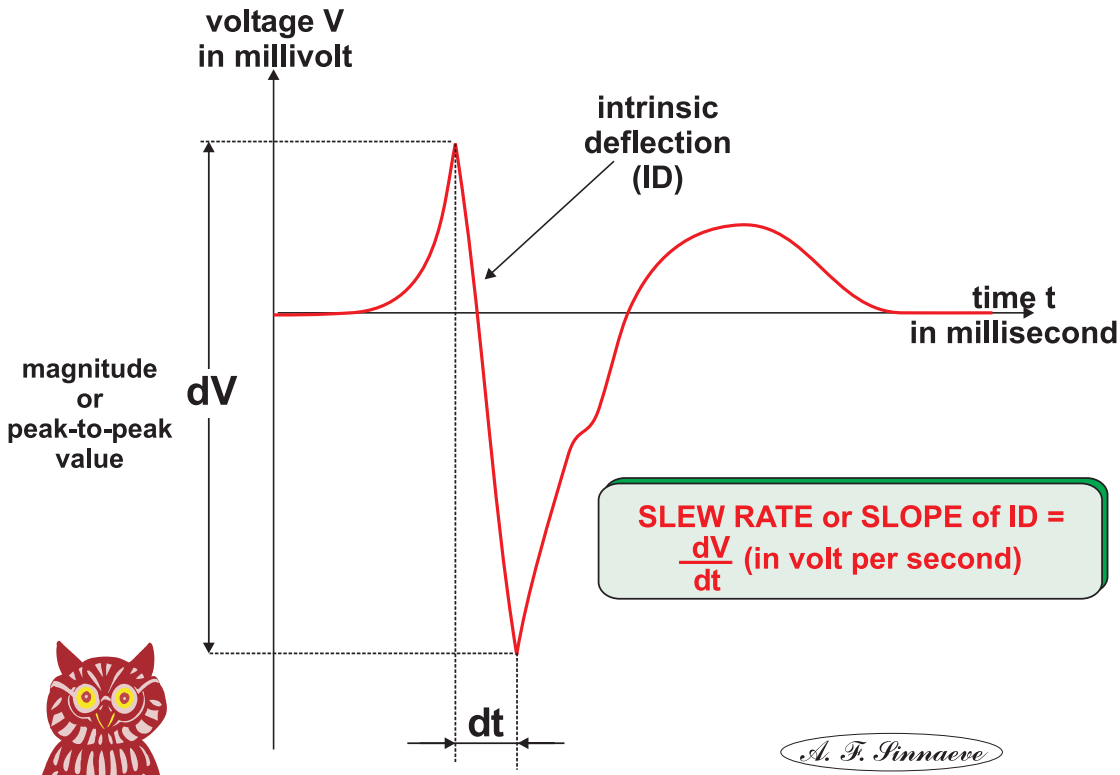
VENTRICULAR ELECTROGRAM
INTRINSIC DEFLECTION & SLEW RATE

INTRINSIC DEFLECTION :

The rapid biphasic portion of the endocardial electrogram which occurs as the myocardium underlying the electrode depolarizes

SLEW RATE :

The rate of change in signal amplitude per unit of time

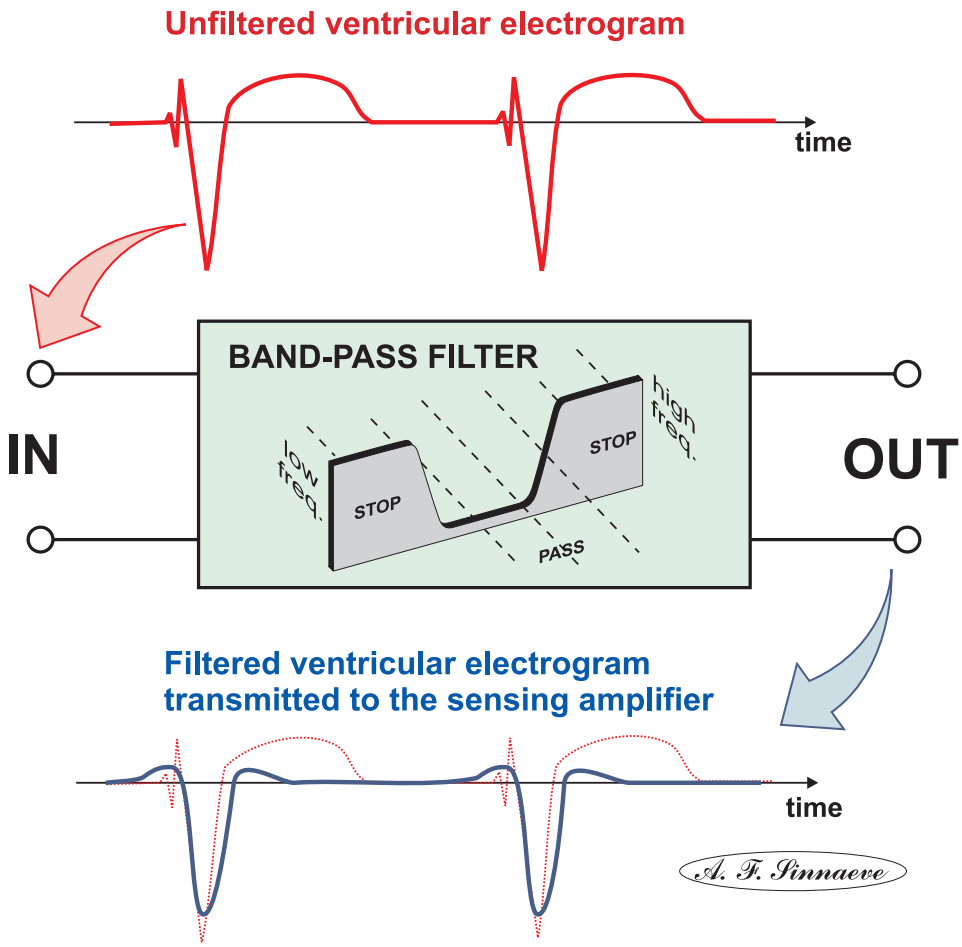


SLEW RATE or SLOPE of ID = $\frac{dV}{dt}$ (in volt per second)

A. F. Sinnaeve

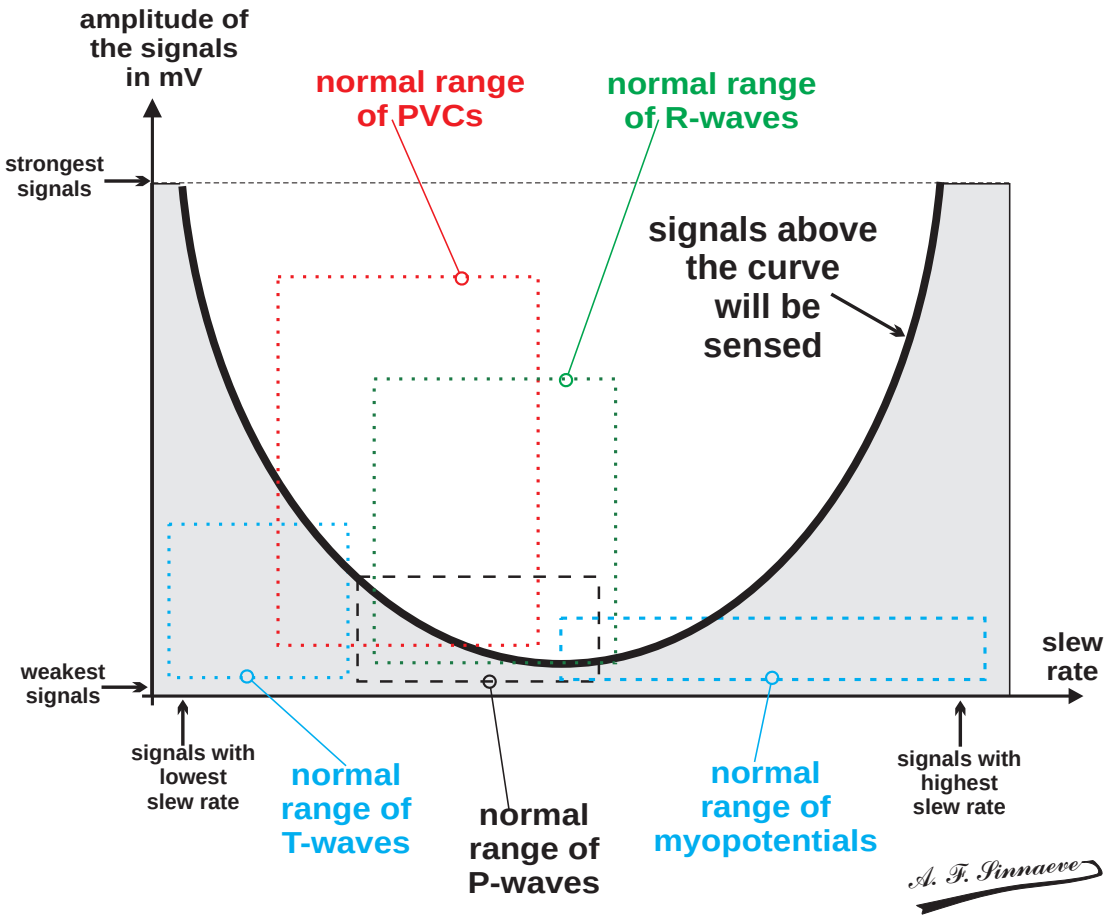
A large intracardiac signal (electrogram or EGM) almost always has a good (i.e. sharp rising) slew rate for sensing. The slew rate becomes important in relatively small signals : in this situation a pacemaker may not be able to sense an EGM with a slow-rising slope. The slew rate can be determined at the time of implantation. Although the EGM can be visualized noninvasively after implantation, the slew rate cannot !

FILTERING OF THE ENDOCARDIAL SIGNAL



Heart signals with the right slew rate easily pass through the filter without attenuation and can affect the timer of the pacemaker.
Signals with a very high slew rate (i.e. changing very rapidly) probably originate from an external source (myopotentials from skeletal muscles, electromagnetic interference, etc.). They are strongly attenuated so that they no longer can affect the timer. Signals with a very low slew rate corresponding with T waves are also strongly attenuated and unable to affect the timer of the pacemaker.
Only signals with the right slew rate i.e. with the right frequency content, will pass through the filter without attenuation, hence the name “band-pass filter”.

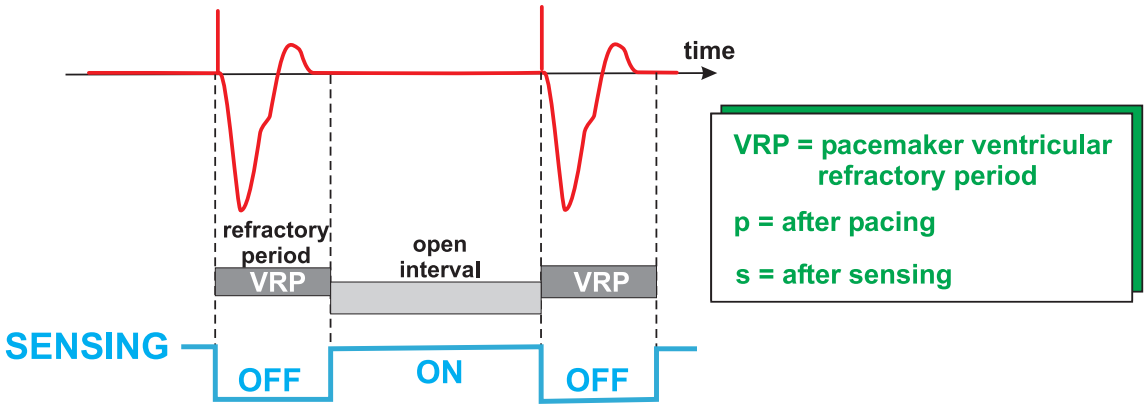
THE FILTERING OF SENSED SIGNALS



Signals are characterized by their amplitude and their slew rate. Each rectangle is the idealized representation of the set of all possible amplitude & slew rate combinations that are typical for a specific heart signal. Obviously these sets of values overlap each other and discrimination by slew rate only is not possible; a level detector will be necessary.
The shape of the filter characteristic above which detection is guaranteed, is always a technical compromise. Apparently some amplitude & slew rate combinations for T-waves and myopotentials may be above the detection level and can be sensed (over-sensing). Some combinations for PVCs and R- waves are beneath the detection level and cannot be detected (undersensing).

Abbreviations : PVC = premature ventricular complex

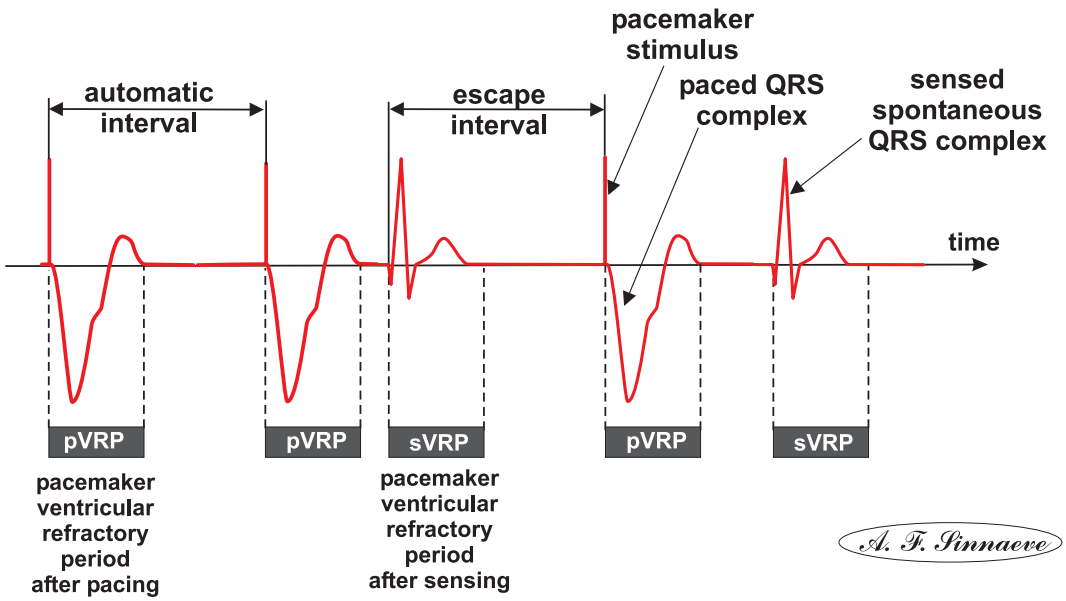
THE PACEMAKER REFRACTORY PERIOD TRADITIONAL CONCEPT



VRP = pacemaker ventricular refractory period

p = after pacing

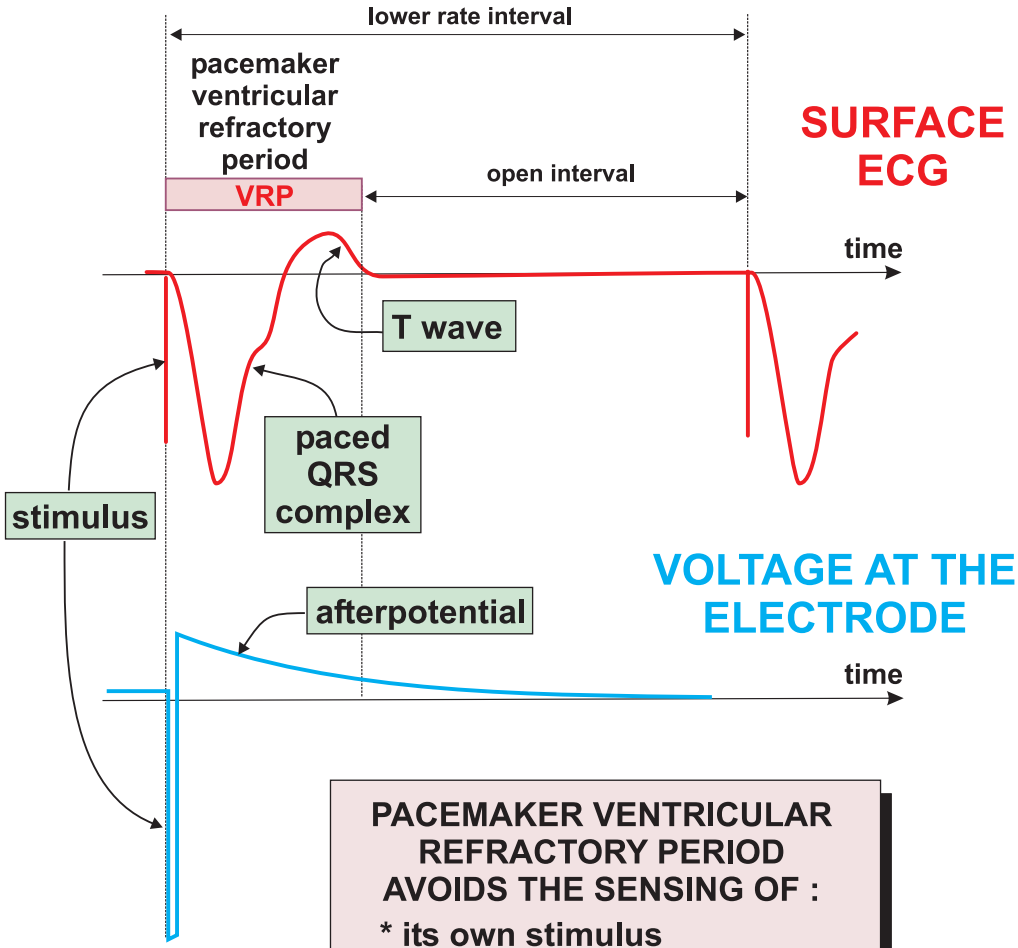
s = after sensing



A. F. Sinnaeve

pVRP is often equal to sVRP

FUNCTIONS OF THE PACEMAKER
VENTRICULAR REFRACTORY PERIOD



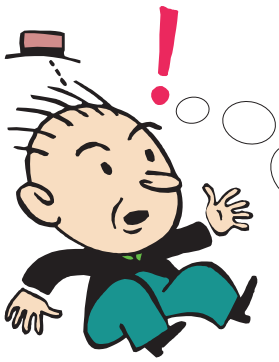
PACEMAKER VENTRICULAR REFRACTORY PERIOD AVOIDS THE SENSING OF :

* its own stimulus
* the paced QRS complex
* the T wave
* (excessive) afterpotential
* the combination of T wave and afterpotential

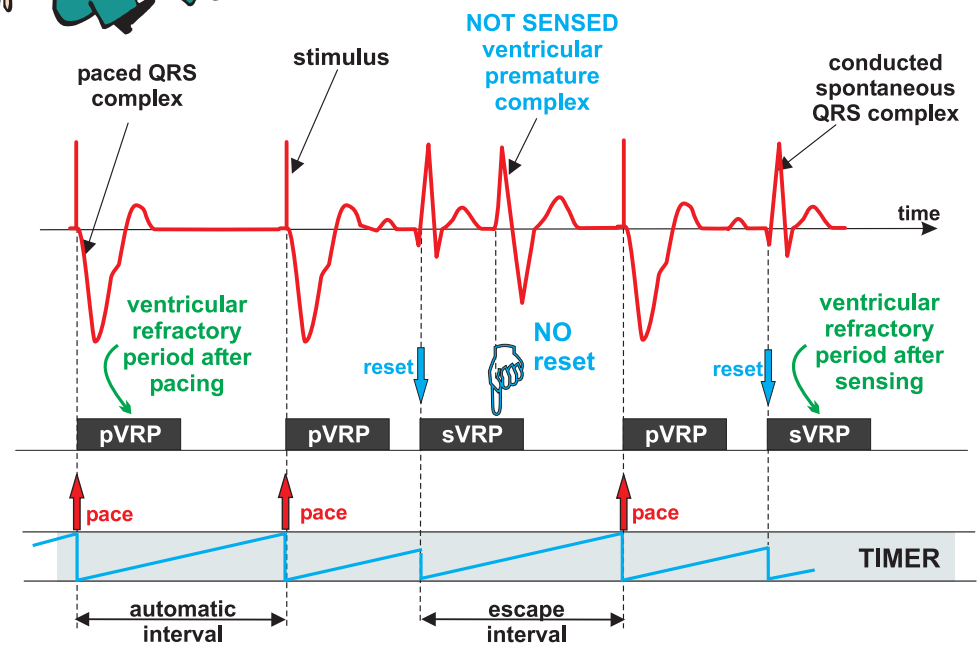
A. F. Sinnaeve

The duration of the pacemaker ventricular refractory period (VRP) is usually 200 - 300 ms

THE PACEMAKER VENTRICULAR REFRACTORY PERIOD



Don’t panic ! It is not a malfunction !

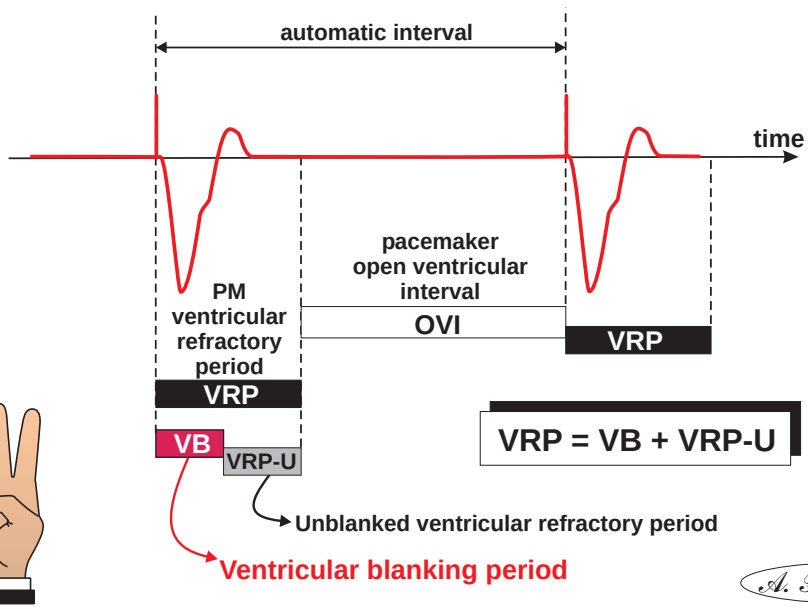


A signal generated during the pacemaker ventricular refractory period can never restart another lower rate interval (corresponding to the lower rate)

A. F. Sinnaeve

Let me tell you some basic facts about timing !

THE BLANKING PERIOD



A. F. Sinnaeve

VRP = pacemaker ventricular refractory period, during which no basic lower rate interval can be started by a detected signal

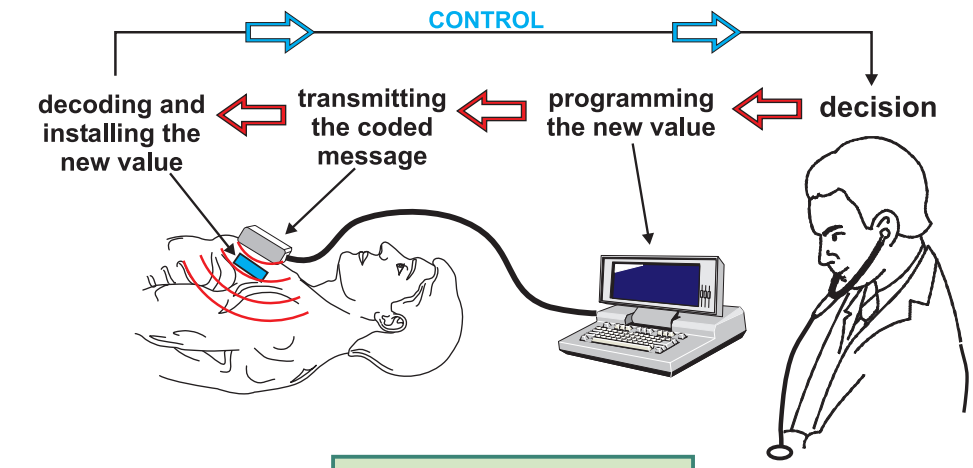
VB = ventricular blanking period during which the detection of all signals is blocked

VRP-U = unblanked ventricular refractory period during which signals can be detected but the lower rate interval cannot be reinitiated. The detected signals in the VRP-U can be used by the pacemaker to control some timing cycles for a variety of functions while the LRI remains unaffected.

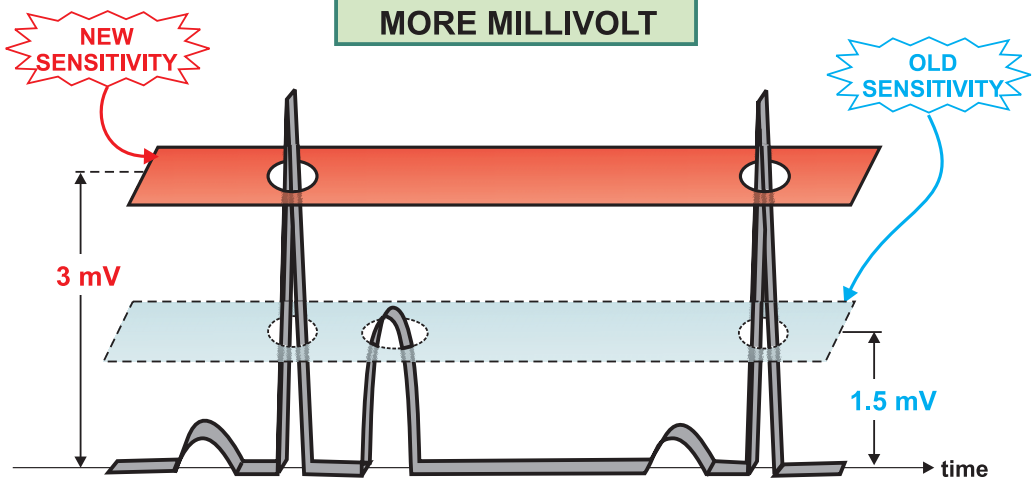
RULE

All refractory periods begin with a blanking period. Blanking periods can be free-standing and need not necessarily be followed by an unblanked refractory period such as VRP-U

PROGRAMMING LOWER SENSITIVITY

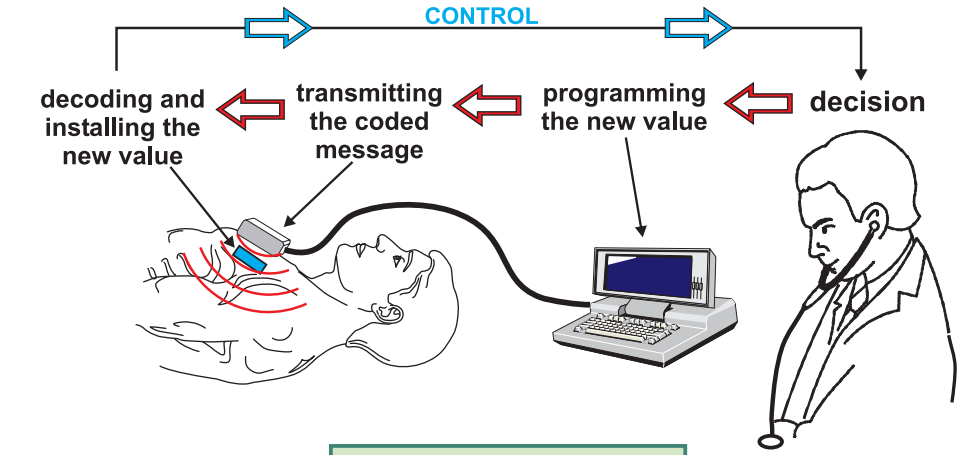


LOWER SENSITIVITY means MORE MILLIVOLT

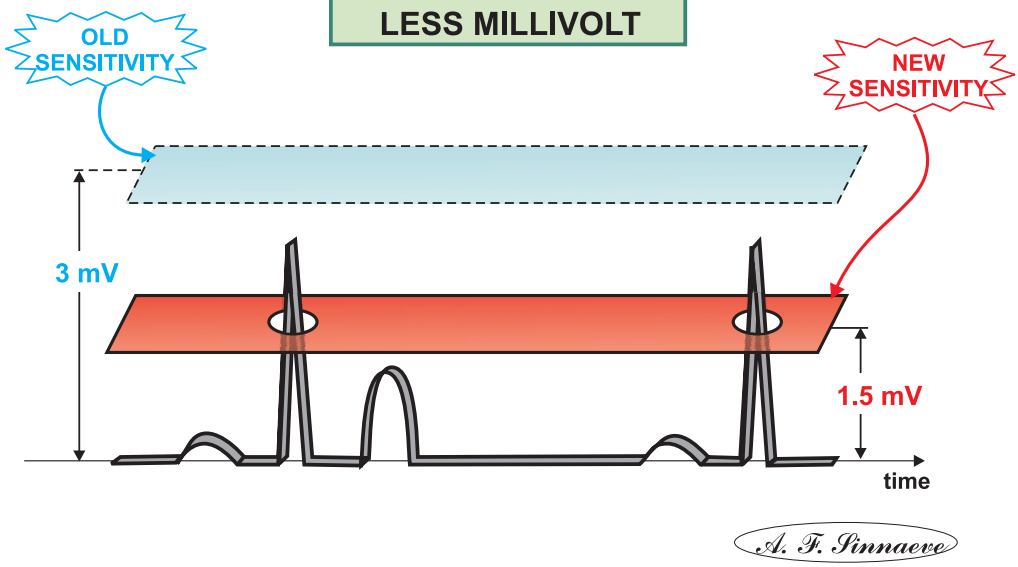


A. F. Sinnaeve

PROGRAMMING HIGHER SENSITIVITY

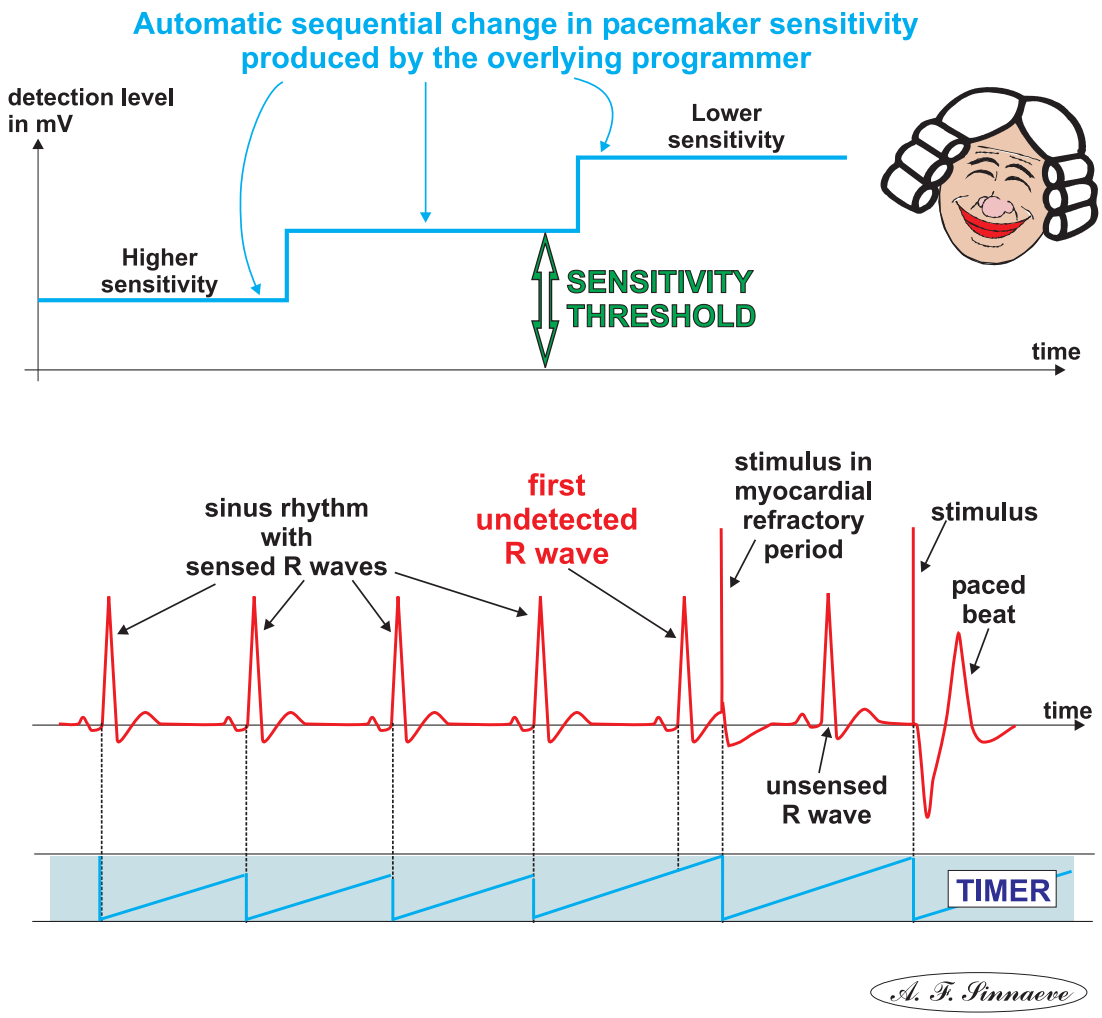


HIGHER SENSITIVITY means LESS MILLIVOLT



A. F. Sinnaeve

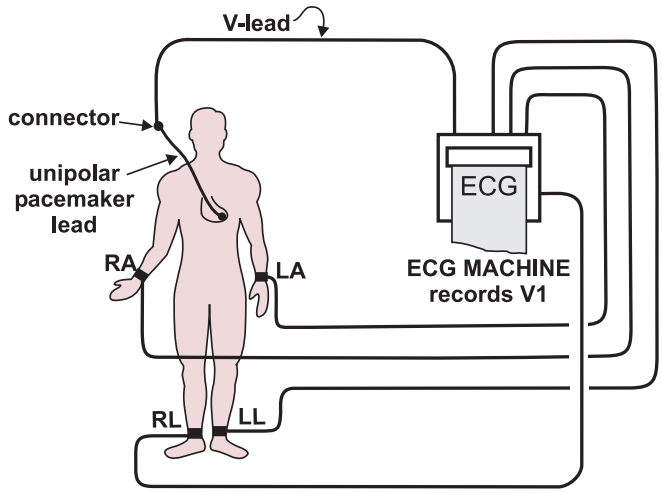
DETERMINATION OF SENSING THRESHOLD



A. F. Sinnaeve

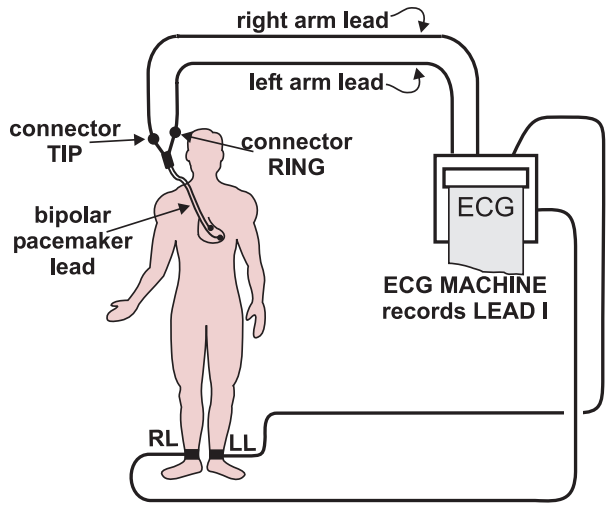
MEASUREMENT OF INTRACARDIAC SIGNALS WITH AN ECG MACHINE AT THE TIME OF IMPLANTATION

UNIPOLAR VENTRICULAR ELECTROGRAM



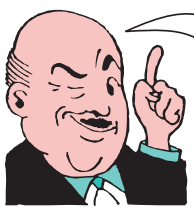
V-lead of ECG machine connected to the unipolar pacemaker lead

BIPOLAR VENTRICULAR ELECTROGRAM

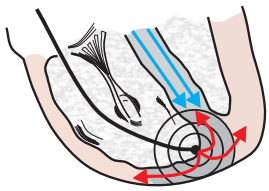


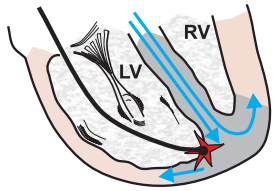
LEAD 1 records the difference between the left arm and the right arm electrodes which is therefore the difference between the two intracardiac electrodes

A. F. Sinnaeve



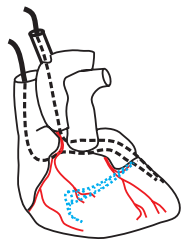
It is important to know that the signal (electrogram) available for sensing by a pacemaker can be easily measured with an ECG machine at the time of implantation. This procedure is sometimes neglected. After implantation, the electrogram can be transmitted noninvasively by telemetry to an appropriate programmer.

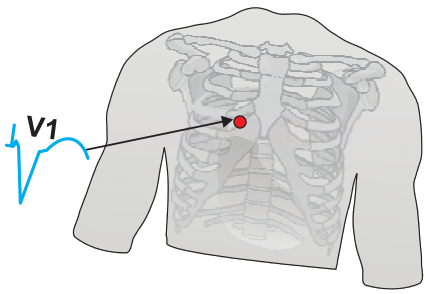


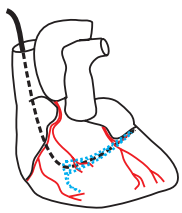


BASIC PACEMAKER ELECTROCARDIOGRAPHY

* ECG of right ventricular pacing : right ventricular apex (RVA) and right ventricular outflow tract (RVOT)
* Axis in the frontal plane with RVA & RVOT pacing
* Myocardial infarct and RV pacing
* Pacing and memory effect
* Patterns of atrial activity with ventricular pacing
* Ventricular fusion
* Ventricular pseudofusion
* Isoelectric ventricular fusion
* Tall R waves in lead V1
* Left ventricular pacing
* Influence of the ECG machine





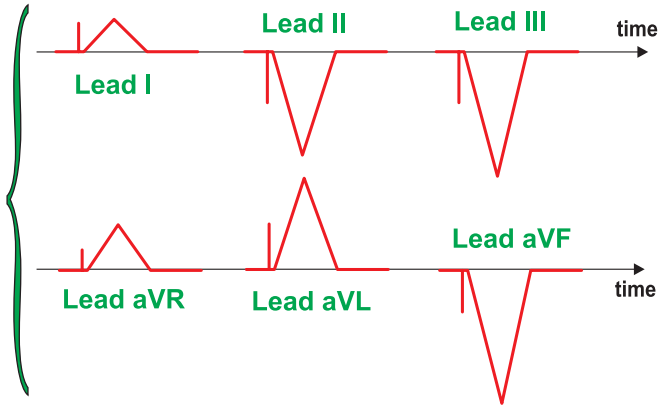


A. F. Sinnaeve

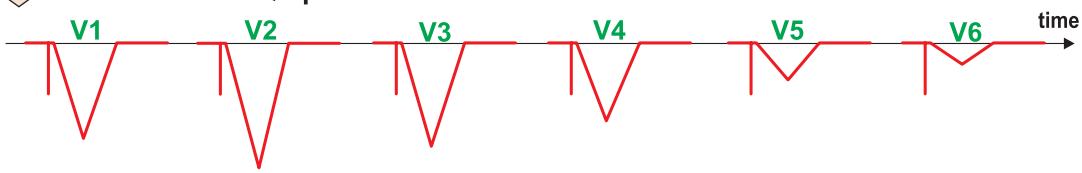
ECG OF RIGHT VENTRICULAR PACING

RV APICAL PACING

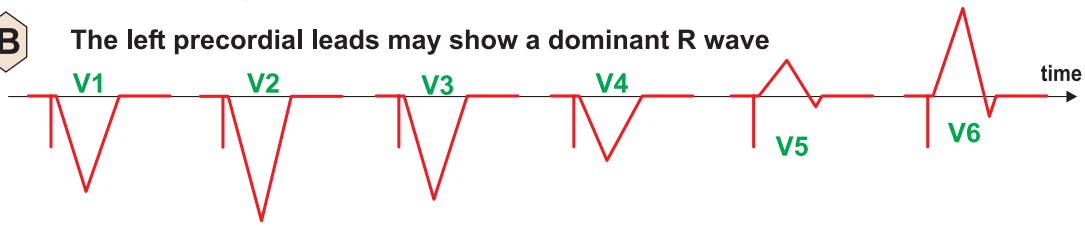
The frontal plane axis is usually left superior . It may also be in the right superior quadrant, where it causes leads I, II & III to be negative and lead aVR to show the largest positive deflection.



A A typical LBBB pattern in the left precordial leads may not be present and all leads show a QS pattern

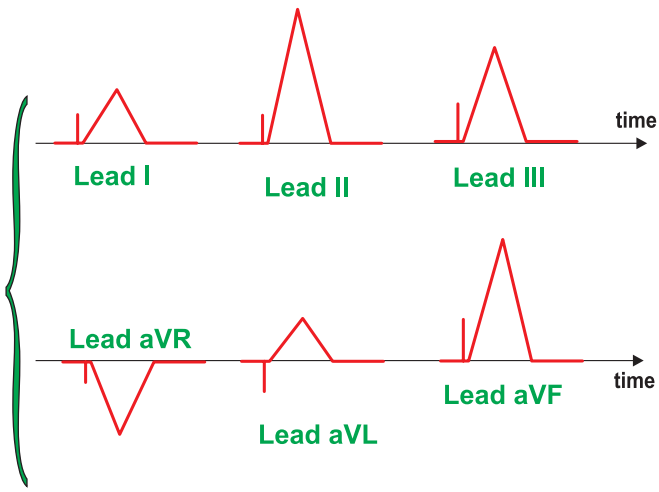


B The left precordial leads may show a dominant R wave



RV OUTFLOW TRACT PACING

The frontal plane axis is normal i.e. as for normally conducted beats. But as the lead moves towards the pulmonary valve, the axis becomes deviated to the right. A qR pattern can occur only in leads I & aVL



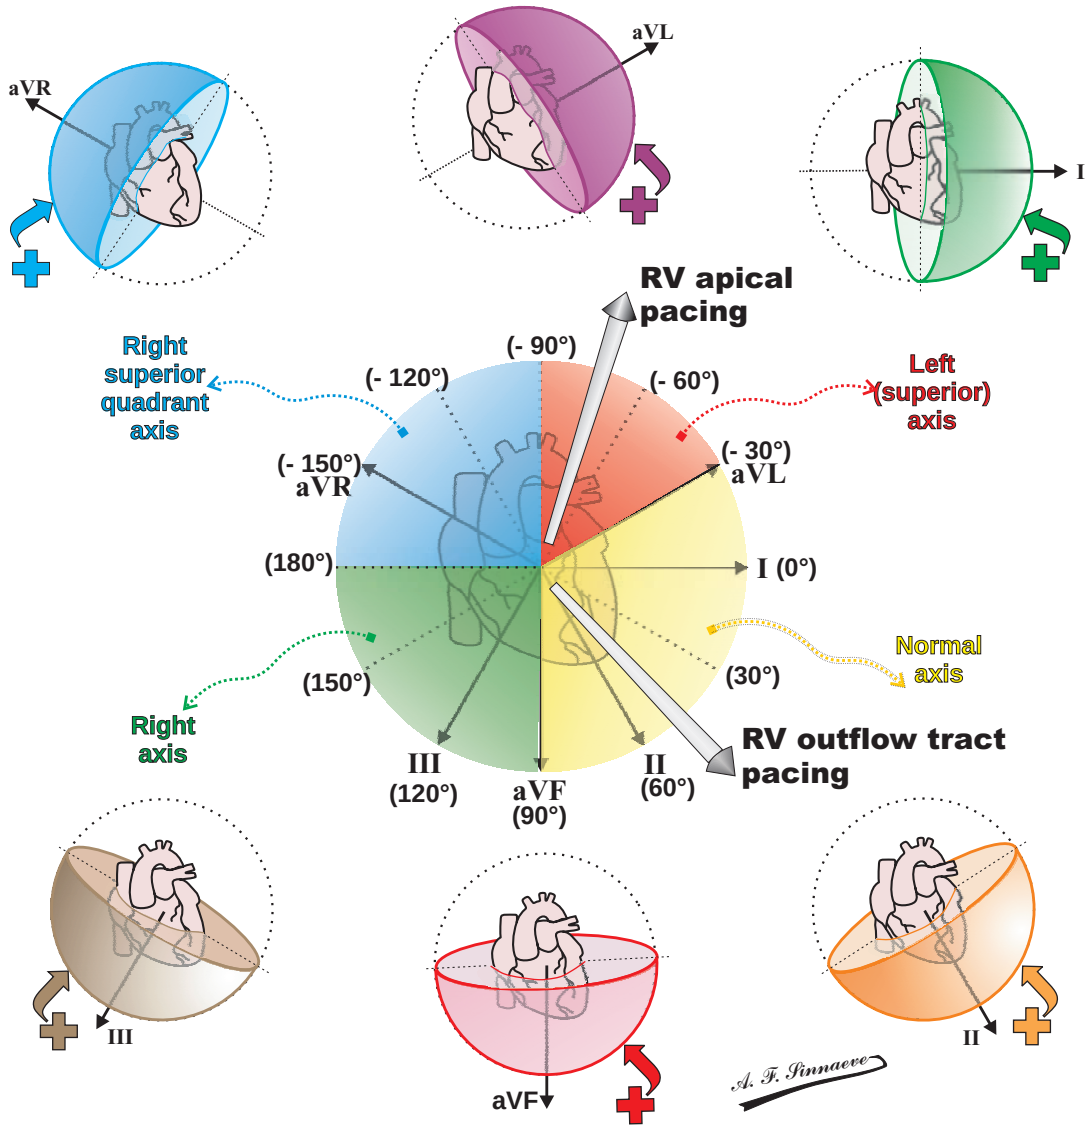
The precordial V leads are similar to those with RV apical pacing !

Abbreviation : LBBB = left bundle branch block

A. F. Sinnaeve

THE MEAN QRS AXIS IN THE FRONTAL PLANE DURING RIGHT VENTRICULAR PACING

During pacing the mean frontal plane QRS axis reflects the site of the pacing !

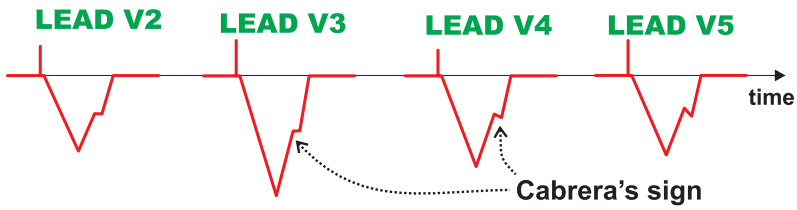


Right ventricular apical pacing activates the inferior part of the heart first. The activation then moves superiorly away from the inferior ECG leads (II, III and aVF) towards the superior leads. The mean frontal plane axis of the paced QRS complex lies superiorly in the left upper quadrant but sometimes in the right superior quadrant. In the latter case, leads I, II and aVF will be negative.
Right ventricular outflow tract pacing, produces a mean frontal plane axis of the paced beat in a direction seen with spontaneous activation of a normal heart: left lower quadrant or “normal” axis. Pacing more superiorly near the pulmonary valve produces right axis deviation: right lower quadrant.

You cannot imagine what little details these cardiologists are looking at ...!

RIGHT VENTRICULAR PACING & OLD ANTERIOR MYOCARDIAL INFARCT

A qR or Qr pattern in leads V5 and V6 often indicates an old anterior myocardial infarct (MI). This pattern may also occur in leads I and aVL.



A. F. Sinnaeve

A shelf like notch (0.04sec) on the ascending limb of the S wave, called Cabrera's sign, in leads V2 - V5 often indicates an old anterior myocardial infarct.

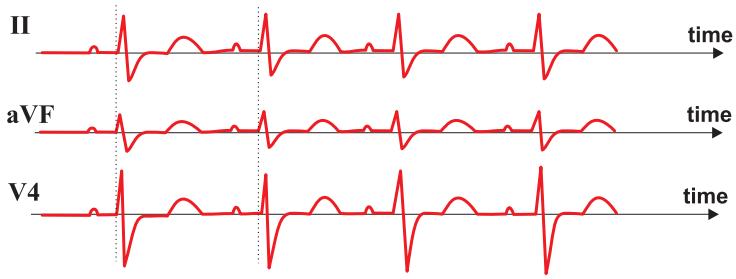
In the case of Cabrera's sign, rule out ventricular fusion beats and retrograde P waves

Wow ! The heart has a memory and therefore a brain. I'm flabbergasted !!!

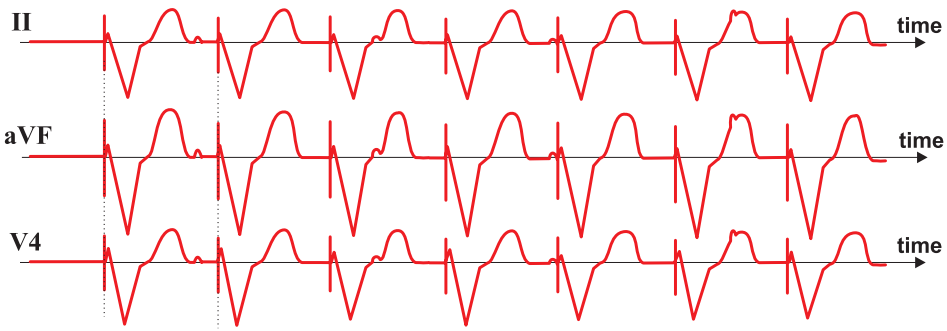
VENTRICULAR PACING & THE MEMORY EFFECT

The underlying ECG cannot be used for the diagnosis of cardiac ischemia because inverted T waves may be due to the memory effect !!!

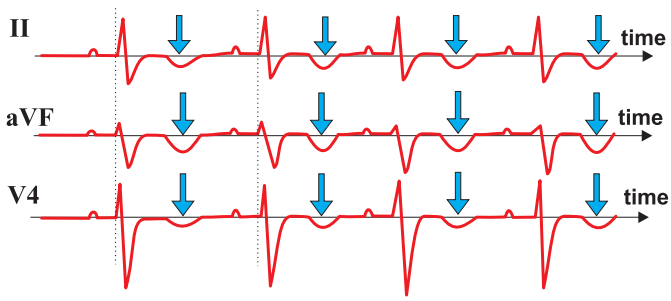
BEFORE PACING



DURING PACING



AFTER PACING



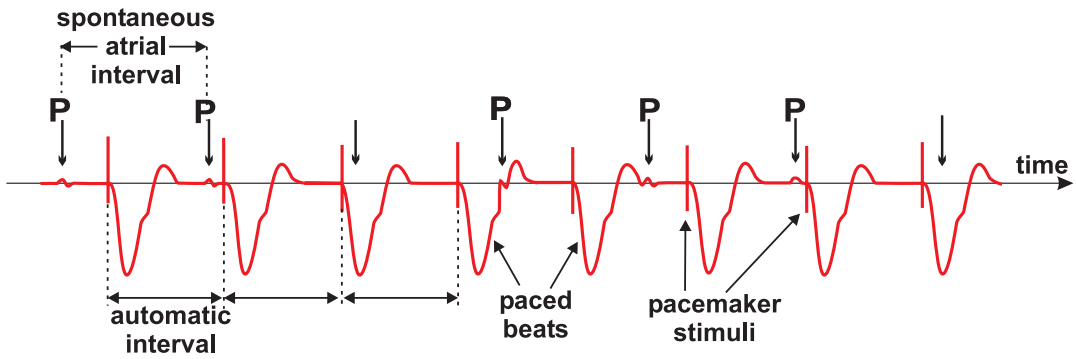
For some time after pacing, the heart seems to remember the abnormal depolarizations.
The duration of the memory effect (negative T waves) depends upon the duration of pacing

A. F. Sinnaeve

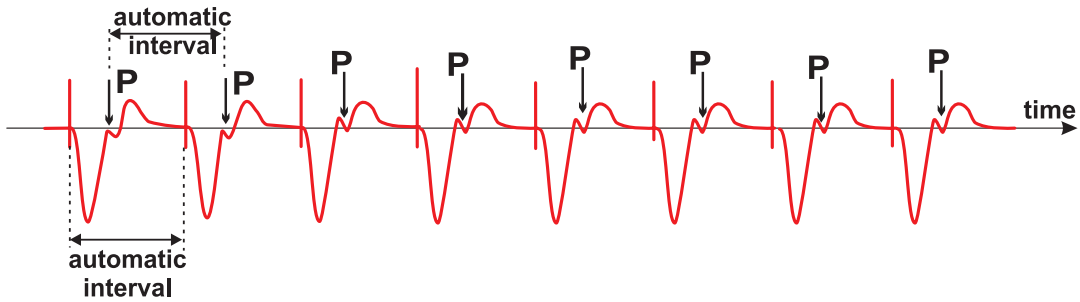
PATTERNS OF ATRIAL ACTIVITY DURING VENTRICULAR PACING

AV dissociation during pacing

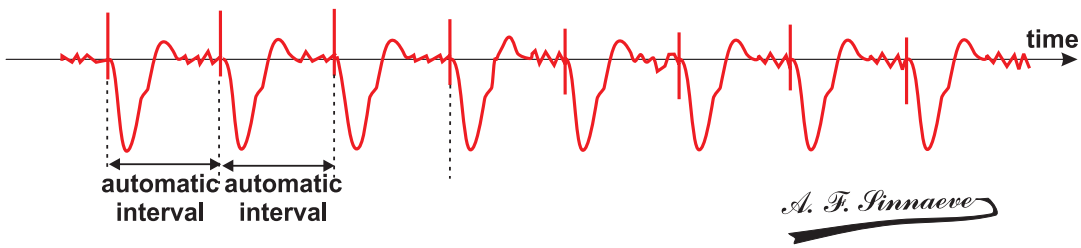
P waves march through the paced QRS complexes



Retrograde ventriculoatrial conduction during pacing



Atrial fibrillation during pacing

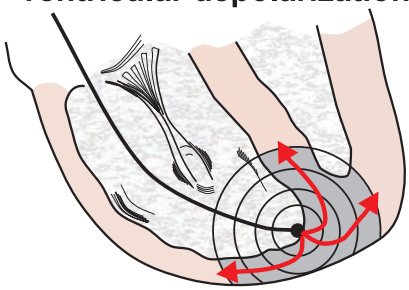


A. F. Sinnaeve

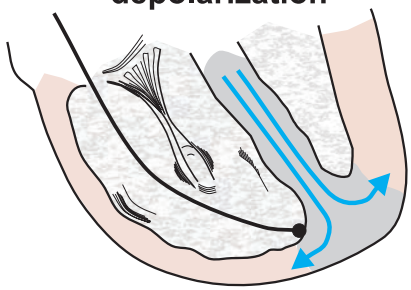
Attention please ! Peculiar QRS complexes may be seen !!!

VENTRICULAR FUSION BEAT

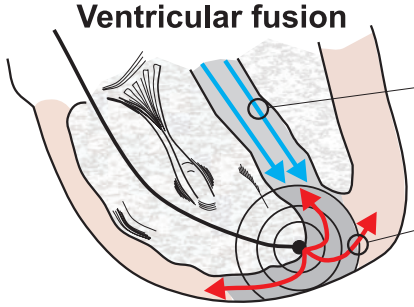
Pacemaker-induced ventricular depolarization



Spontaneous ventricular depolarization

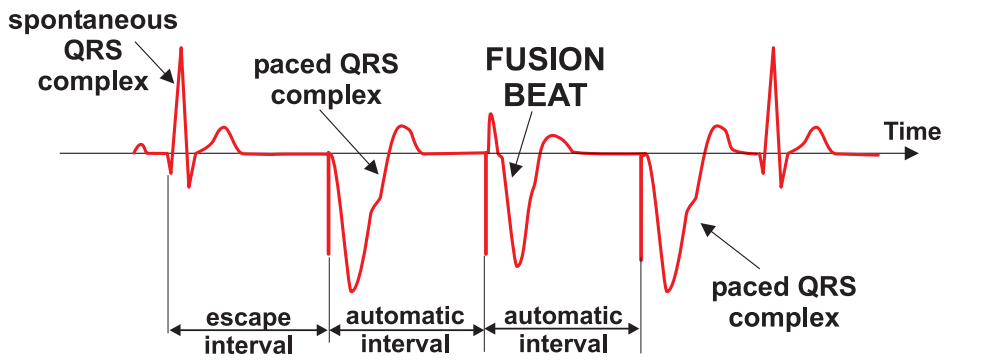


Ventricular fusion



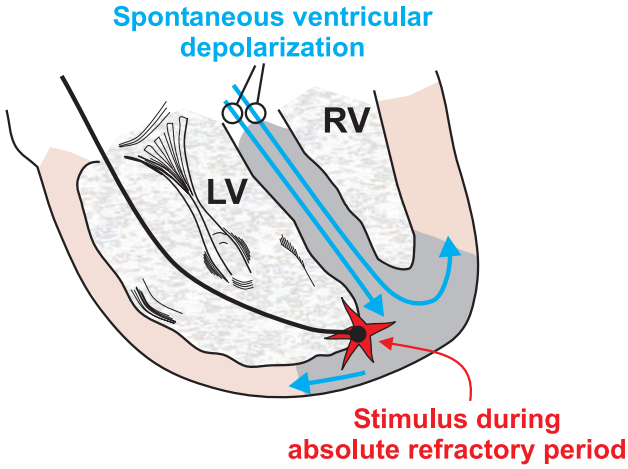
rapid conduction via Purkinje fibers

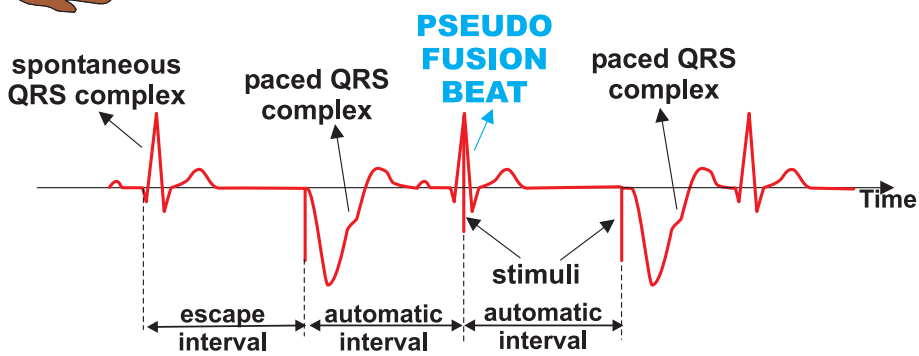
slower conduction via ordinary myocardial cells



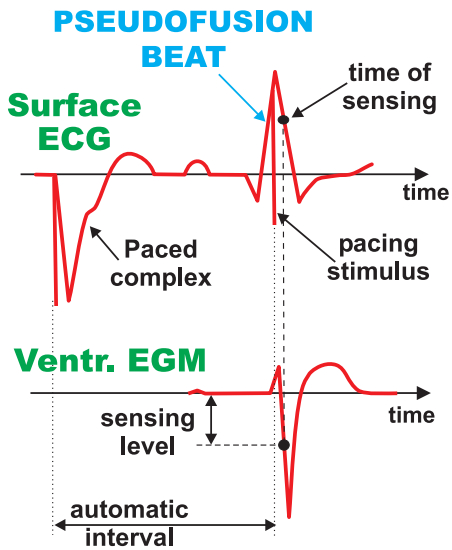
A. F. Sinnaeve

VENTRICULAR PSEUDOFUSION BEAT





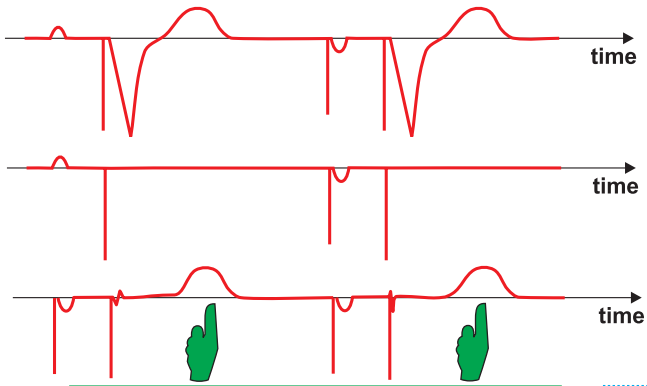
The pacemaker senses the intracardiac ventricular electrogram registered between the 2 pacing electrodes. A substantial portion of the surface QRS complex can be inscribed before the intracardiac electrogram generates the required voltage (according to the programmed sensitivity) to inhibit the ventricular channel of a VVI pacemaker. Consequently a VVI pacemaker can deliver a ventricular stimulus within the spontaneous QRS complex (recorded in the surface ECG) before the device has the opportunity to sense the "delayed" electrogram generated in the right ventricle as the depolarization reaches the electrode(s). The PM stimulus can therefore fall in the absolute refractory period of the ventricular myocardium when it cannot depolarize any portion of the ventricles. True ventricular fusion does not occur. In other words depolarization originates from only one focus !



A. F. Sinnaeve

ISOELECTRIC VENTRICULAR FUSION BEATS

Pay attention !!!
The pacemaker may function normally while no QRS complexes are seen on the surface ECG



Normal paced ventricular complexes : a depolarization is followed by a repolarization.

There is loss of capture here !
No depolarization is seen.

ISOELECTRIC FUSION BEATS !
The QRS complex may be so narrow as to resemble a stimulus or even zero !!!

Look at the T wave !!! If there is a repolarization, a depolarization has occurred before !

Note that this appearance is seen in only one ECG lead. To confirm the diagnosis, look at different ECG leads where the QRS complex of the ventricular fusion beat will be visible.

What about the atrium ?
I often see no atrial activity on the monitoring lead.

A. F. Sinnaeve

You have to realize that the P wave is much smaller than the QRS complex and evaluation of atrial activity in the ECG can sometimes be tricky ! Isoelectric atrial fusion beats may occur but are rare. An isoelectric or flat segment between an atrial and ventricular stimulus can be due to successful atrial capture which is not visible in a particular ECG lead. Again, one must examine other ECG leads to determine the presence of a paced P wave and sometimes take an ECG at double standardization to bring out the P wave

SIGNIFICANCE OF A DOMINANT R WAVE OF PACED VENTRICULAR BEATS IN LEAD V1 DURING TRANSVENOUS PACING

A lead in the LV via a foramen ovale !!!

This would not have happened if a 12 lead ECG had been taken at the time of pacemaker implantation to exclude a dominant R wave of the paced beats in the right-sided chest leads !

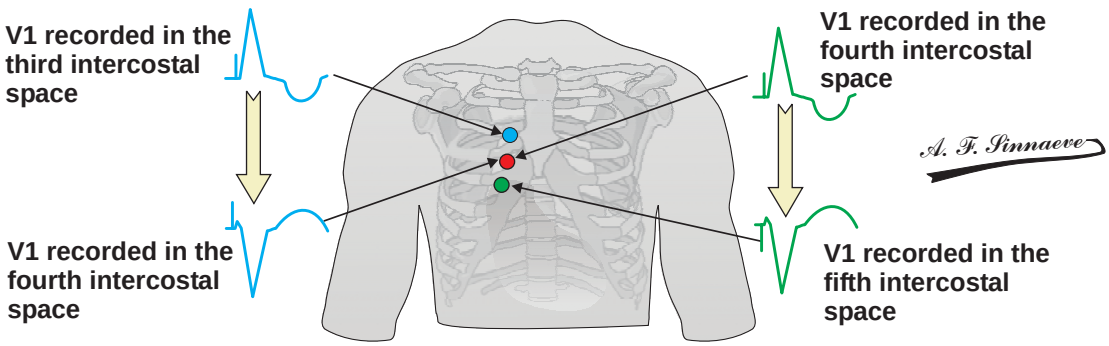
CAUSES OF A DOMINANT R WAVE IN V1

1. Ventricular fusion with spontaneous beats conducted with an RBBB pattern
2. A paced beat in the relative refractory period of the heart resulting in aberrant conduction with RBBB morphology
3. Left ventricular (LV) endocardial stimulation
4. A catheter in the coronary sinus or middle cardiac vein activating the LV epicardial surface
5. A change of electrically induced ventricular depolarization from LBBB to RBBB strongly suggesting catheter perforation of the free wall of RV or the ventricular septum with LV stimulation
6. Uncomplicated RV pacing as shown below

CAUTION

CHECK THE POSITION OF THE LEADS VERY CAREFULLY

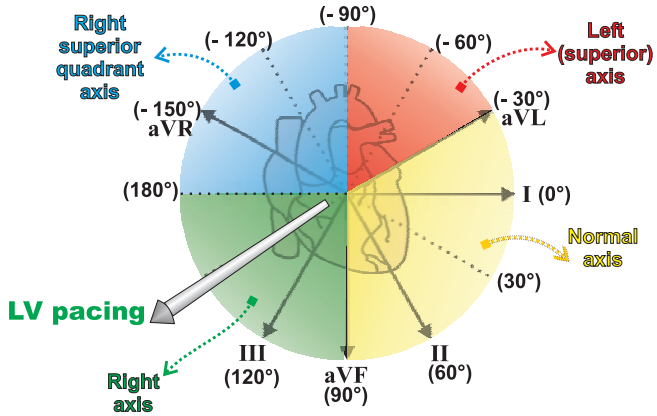
* The positivity of V1 depends upon the correct position of the chest (V) electrode
* A dominant R wave may be seen during uncomplicated RV apical pacing



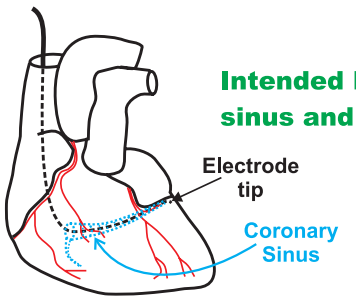
A. F. Sinnaeve

Abbreviations : LBBB = left bundle branch block ; LV = left ventricle ; RBBB = right bundle branch block ; RV = right ventricle ; **Foramen ovale** is a potential communication from the right atrium to the left atrium that may allow passage of a pacemaker lead from the right atrium to the left one and then to the left ventricle. The lead in the left ventricle may appear to be in the right ventricle on standard fluoroscopy.

LEFT VENTRICULAR PACING

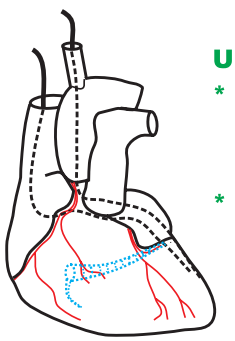


The mean frontal plane axis of the paced beat is directed to the right lower quadrant (right axis deviation). There is a characteristic tall R wave in lead V1 to at least V3 and often further into the left precordial leads.



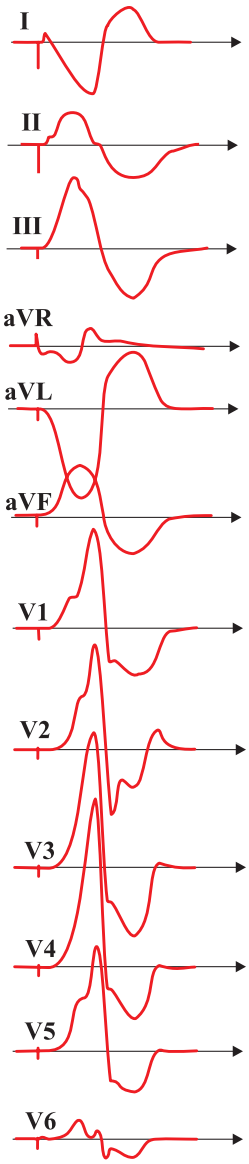
Intended LV pacing via coronary sinus and coronary vein

A. F. Sinnaeve



Unintended LV pacing :

* **Passage of lead into LV via patent foramen ovale (from right atrium to left atrium and LV)**
* **Via subclavian artery (across the aortic valve) mistaken for the subclavian vein**



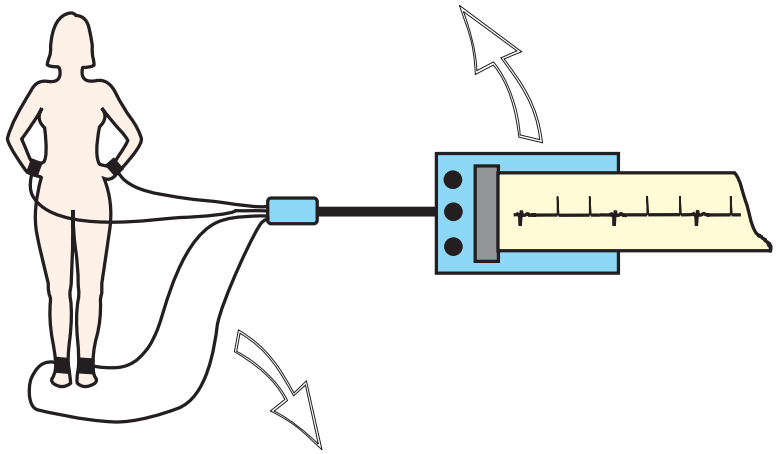
DANGER

A lead within the LV cavity (endocardial site) may cause thrombus formation, cerebral emboli and stroke.
The diagnosis of LV endocardial lead misplacement should be suspected if there is a tall R wave at least in leads V1 to V3 and sometimes further in the left-sided precordial leads. The definitive diagnosis requires echocardiography especially by the transesophageal method.

INFLUENCE OF THE ECG-MACHINE

I think there is no capture here !
All I see are some ventricular escape beats...

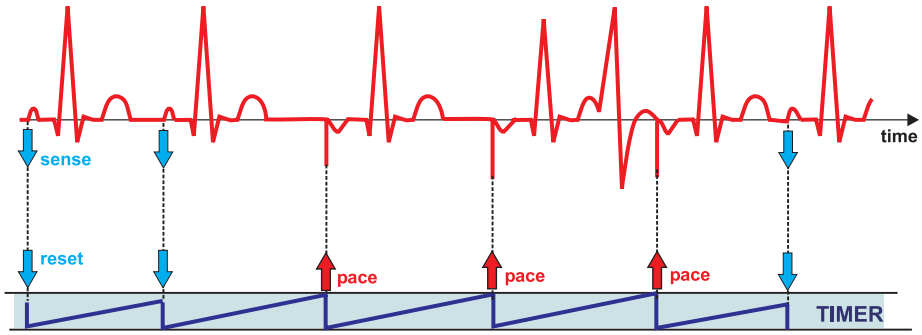
Surface ECG shown on saturated ECG machine



Same ECG with properly adjusted ECG machine

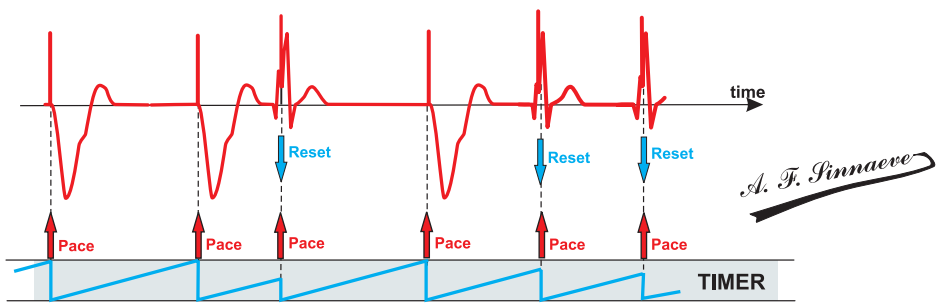
A. F. Sinnaeve

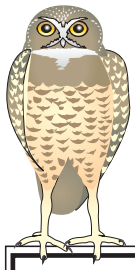
In some ECG machines, when the automatic gain control (AGC) is not activated, the input circuit may be saturated by large unipolar stimuli. During this saturation the machine is unable to detect any small signals and it is impossible to see if the stimuli capture the heart or not.



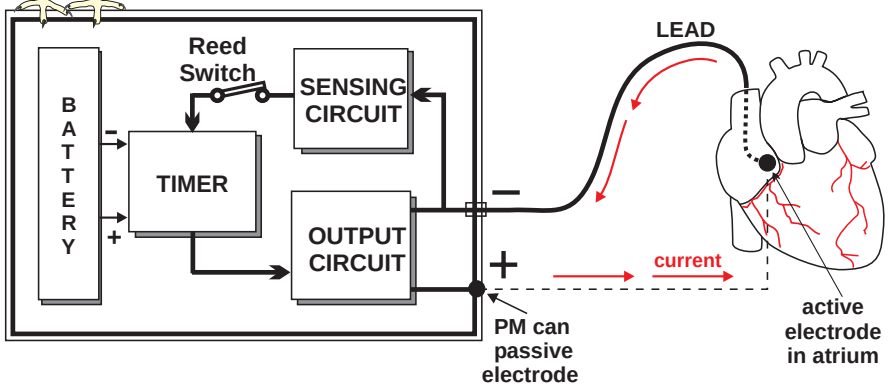
OTHER SINGLE CHAMBER PACEMAKERS

* The AAI pacing mode
* The VVT pacing mode

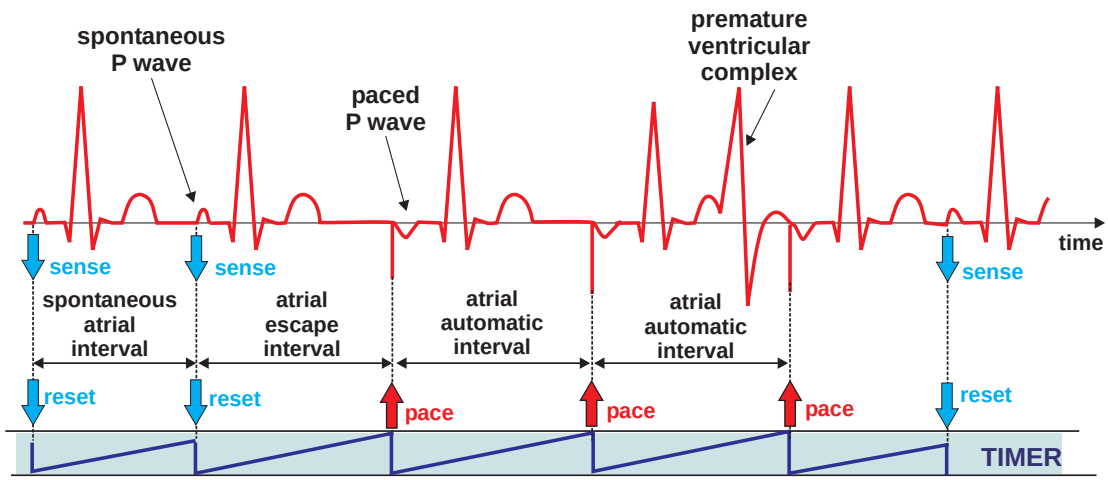




THE AAI PACEMAKER

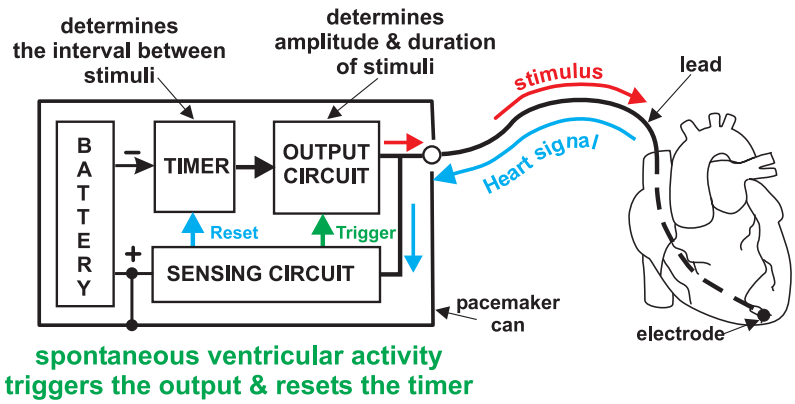


Compared to the VVI pacemaker the SENSITIVITY should be higher (i.e. a lower number in mV) because P waves have lower amplitudes than R waves



A. F. Sinnaeve

THE VVT MODE



spontaneous ventricular activity
triggers the output & resets the timer

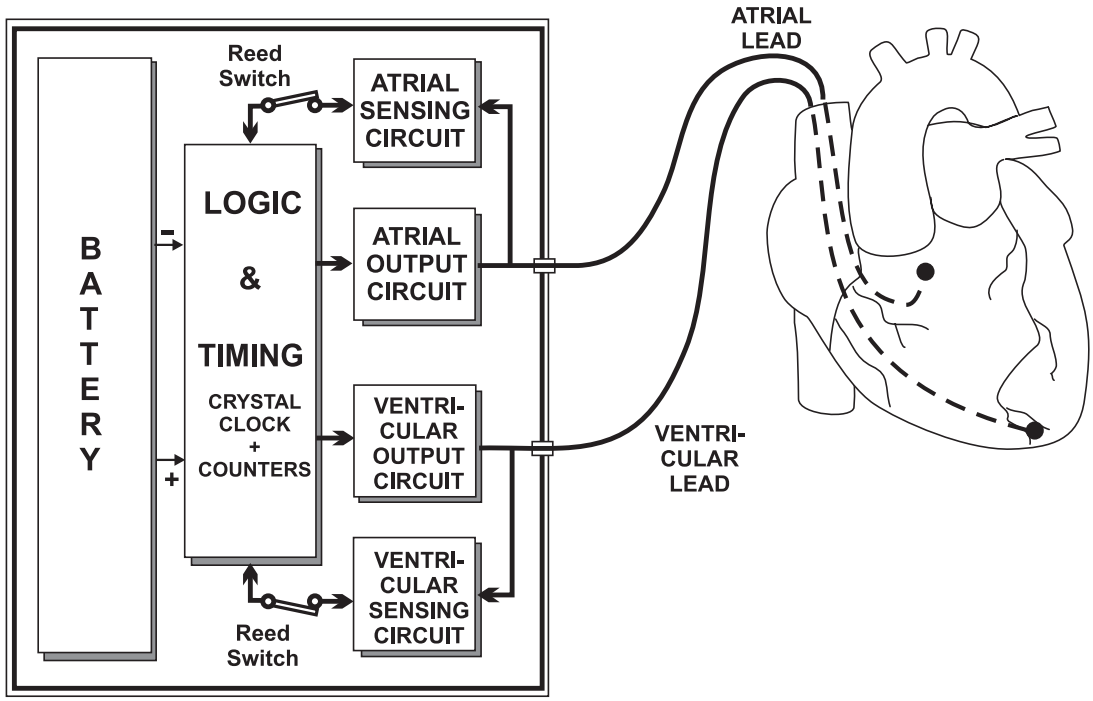
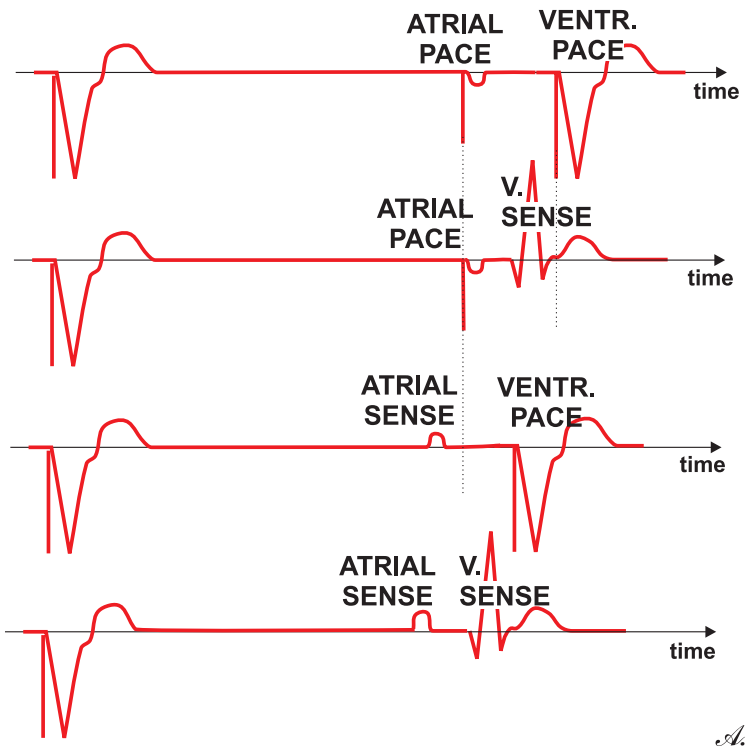
DUAL CHAMBER PACING



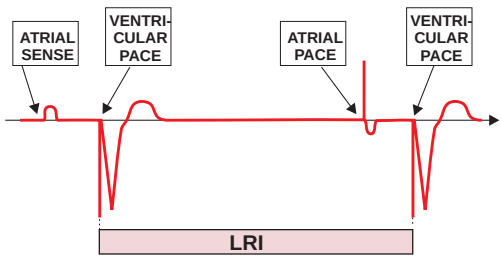


A. F. Sinnaeve

THE 4 FUNDAMENTAL TIMING CYCLES OF A DDD PACEMAKER

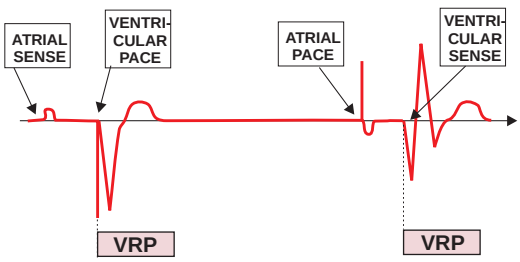
PART 1 : THE VENTRICULAR CHANNEL

FUNDAMENTAL TIMING CYCLE 1
LRI = LOWER RATE INTERVAL



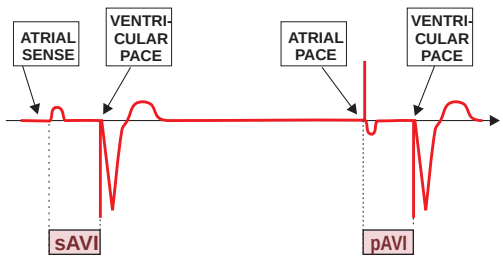
Longest interval between a paced or sensed ventricular event and the succeeding ventricular paced event without intervening sensed events

FUNDAMENTAL TIMING CYCLE 2
VRP = VENTRICULAR REFRACTORY PERIOD



Interval initiated by a ventricular event during which a new lower rate interval (LRI) cannot be initiated

FUNDAMENTAL TIMING CYCLE 3
AVI = ATRIOVENTRICULAR INTERVAL



Interval between an atrial event and the scheduled delivery of a ventricular stimulus

sAVI = after a sensed atrial event
pAVI = after a paced atrial event

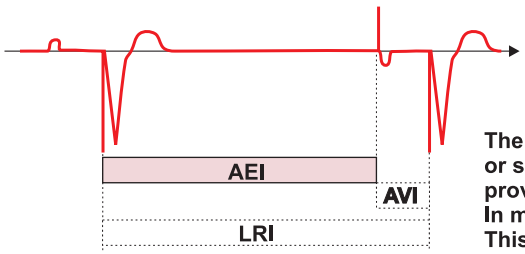
A. F. Sinnaeve

*** the electronic analog of the P-R interval**
*** the atrial channel is refractory during the AV interval (a new AV delay cannot be initiated when one is already in progress)**

THE 4 FUNDAMENTAL TIMING CYCLES OF A DDD PACEMAKER

PART 2 : THE ATRIAL CHANNEL

DERIVED : AEI = ATRIAL ESCAPE INTERVAL

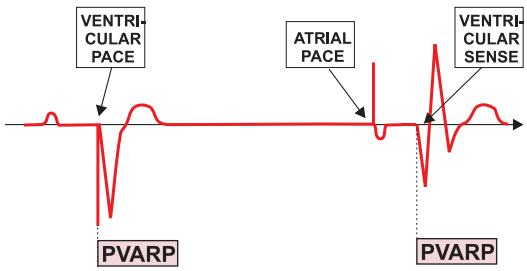


AEI = LRI - AVI

With AVI = AV interval
and LRI = lower rate interval

The atrial escape interval is the interval between a paced or sensed ventricular event to the succeeding atrial stimulus provided there are no intervening sensed events.
In most pacemakers lower rate timing is ventricular-based. This means that the LRI starts with a ventricular event. In such a system the atrial escape interval is always constant.

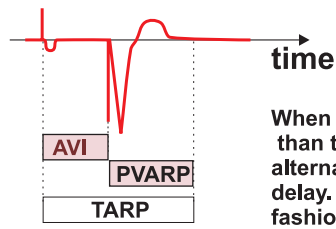
FUNDAMENTAL TIMING CYCLE 4
PVARP = POSTVENTRICULAR REFRACTORY PERIOD



Interval after a ventricular paced or sensed event during which an atrial event cannot initiate a new AVI

* avoids inappropriate atrial sensing of ventricular events
* eliminates sensing of retrograde P waves from ventriculoatrial conduction

DERIVED : TARP = TOTAL ATRIAL REFRACTORY PERIOD



TARP = AVI + PVARP

When the interval between 2 consecutive P waves becomes shorter than the TARP, tracking of every P wave becomes impossible. Every alternate P wave will fall in the PVARP where it cannot initiate an AV delay. The pacemaker will thus respond to the P waves in a 2 : 1 fashion. This form of upper rate response is called 2 : 1 block and the TARP effectively becomes the upper rate interval.

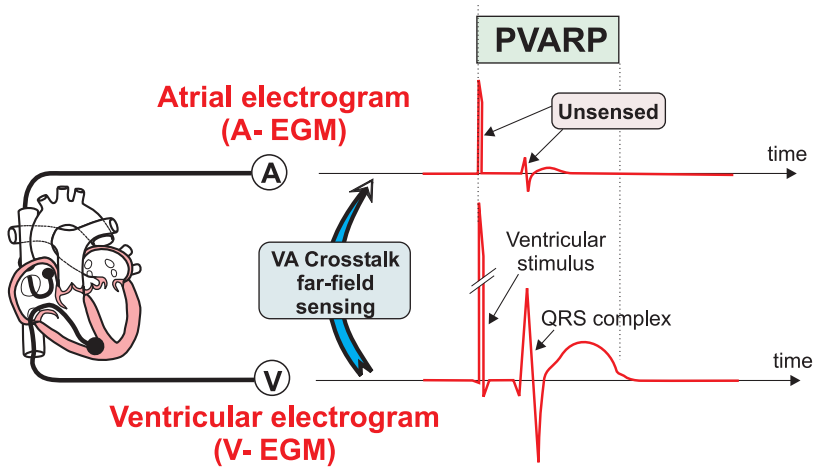
A. F. Sinnaeve

All examples of pacemaker timing in this book involve ventricular-based lower rate timing, unless otherwise specified.

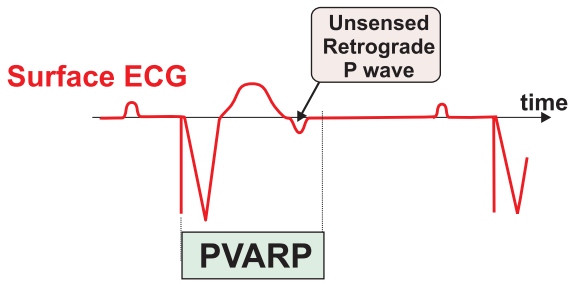
FUNCTIONS OF THE POSTVENTRICULAR ATRIAL REFRACTORY PERIOD (PVARP)

PVARP Interval after a ventricular paced or sensed event during which the atrial channel is refractory !!!

1. Avoids the inappropriate atrial sensing of ventricular events (ventricular stimuli, QRS complexes, aberrant T waves)

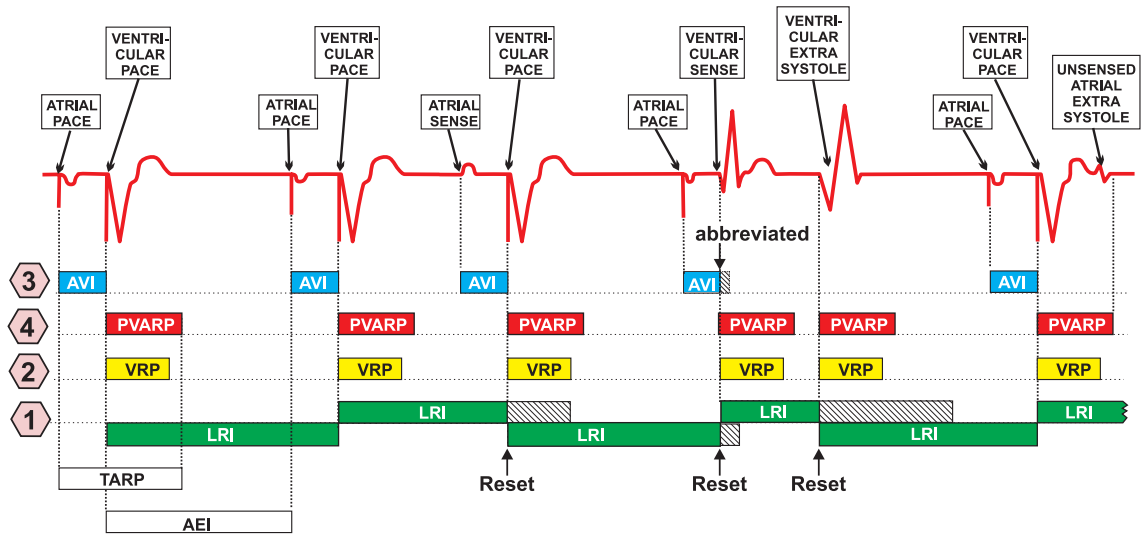


2. Avoids sensing of retrogradely conducted P waves



A. F. Sinnaeve

DDD PACEMAKER WITH 4 TIMING CYCLES AT WORK



FUNDAMENTAL INTERVALS

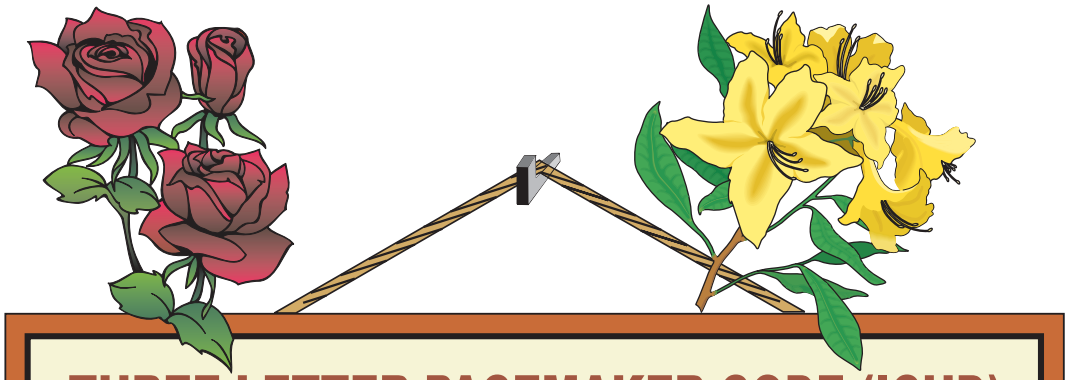
1. LRI = Lower Rate Interval
2. VRP = Ventricular Refractory Period
3. AVI = Atrioventricular Interval
4. PVARP = Postventricular Atrial Refractory Period

DERIVED INTERVALS

TARP = Total Atrial Refractory Period
= AVI + PVARP
= Upper Rate Interval
= URI

AEI = Atrial Escape Interval
= LRI - AVI

A. F. Sinnaeve



THREE-LETTER PACEMAKER CODE (ICHD)

POSITION	1st	2nd	3rd
CATEGORY	CHAMBER(S) PACED	CHAMBER(S) SENSED	MODE OF RESPONSE
LETTERS	V = VENTRICLE A = ATRIUM S = SINGLE D = DOUBLE (V & A)	V = VENTRICLE A = ATRIUM S = SINGLE O = NONE D = DOUBLE (V & A)	T = TRIGGERED I = INHIBITED O = NONE D = DOUBLE inhibited & triggered

EXAMPLE :

DDD = a pacemaker pacing and sensing in both the atrium and the ventricle; pacing is inhibited in the atrial channel by sensed ventricular or atrial activity and is inhibited in the ventricular channel by ventricular activity but triggered by sensing atrial activity.

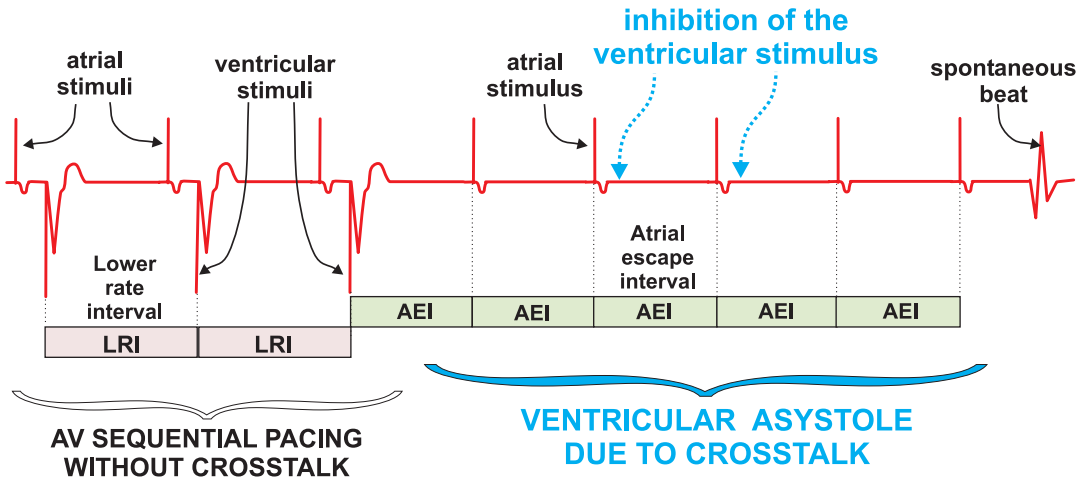
A. F. Sinnaeve

MANIFESTATIONS of AV CROSSTALK

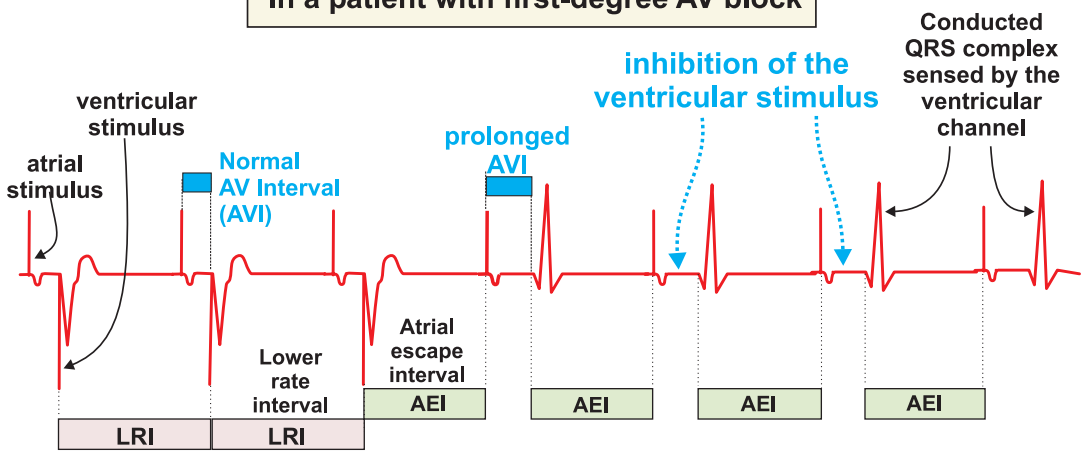
SENSING OF THE ATRIAL STIMULUS BY THE VENTRICULAR CHANNEL

During crosstalk, the atrial pacing rate increases if the ventricular channel does not sense any QRS complexes either because they are absent or they fall in the ventricular refractory period

In a patient without underlying spontaneous rhythm



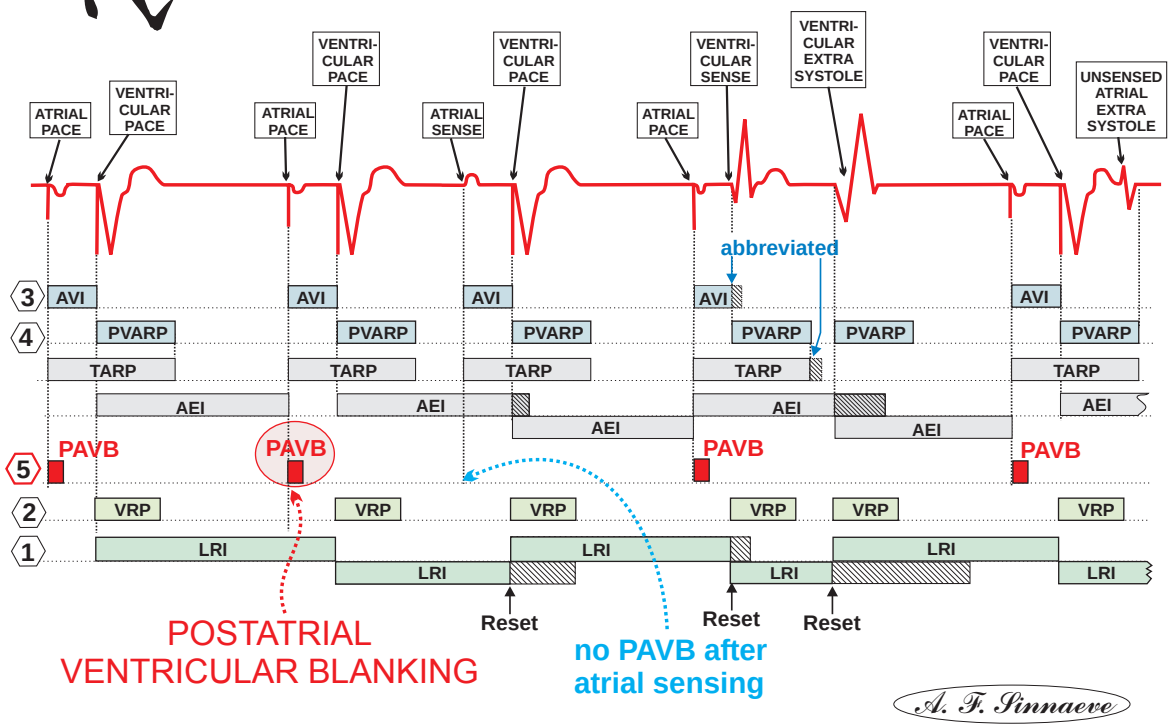
In a patient with first-degree AV block



A. F. Sinnaeve

ADDITION OF A FIFTH TIMING CYCLE TO A SIMPLE DDD PACEMAKER TO PREVENT AV CROSSTALK

Stop the influence of the atrial stimulus upon the ventricular channel !!

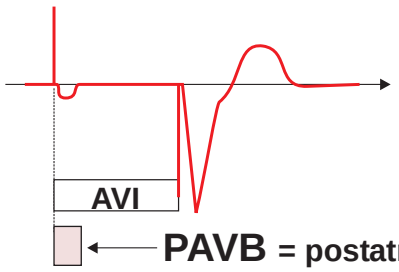


A. F. Sinnaeve

PAVB = a brief interval (10 to 60 ms) initiated by an atrial output pulse when the ventricular channel is switched off and cannot sense.
PAVB is often programmable

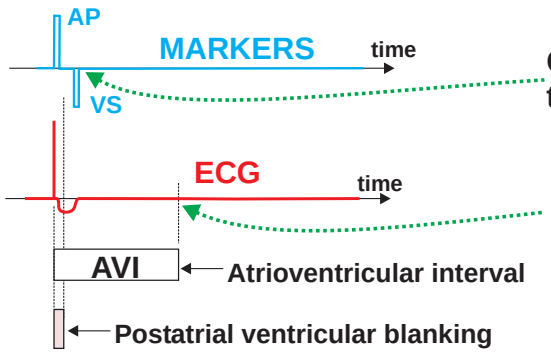
Abbreviations : AEI = atrial escape interval ; AVI = atrioventricular interval ; LRI = lower rate interval ; PAVB = post-atrial ventricular blanking ; PVARP = postventricular atrial refractory period ; TARP = total atrial refractory period ; VRP = ventricular refractory period

THE POSTATRIAL VENTRICULAR BLANKING PERIOD



A brief ventricular interval initiated by an atrial output pulse when the ventricular sensing amplifier is switched off. It prevents AV crosstalk or sensing of the atrial stimulus by the ventricular channel

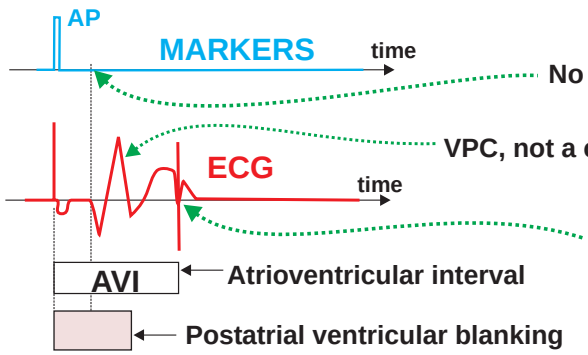
WHEN PAVB IS TOO SHORT : OVERSENSING



Crosstalk : ventricular oversensing of the voltage generated by the atrial pulse

Inhibition of the ventricular pulse "self-inhibition"

WHEN PAVB IS TOO LONG : UNDERSENSING



No ventricular sensing during PAVB

VPC, not a conducted beat from the paced P wave

DANGEROUS : stimulus on T wave

A. F. Sinnaeve

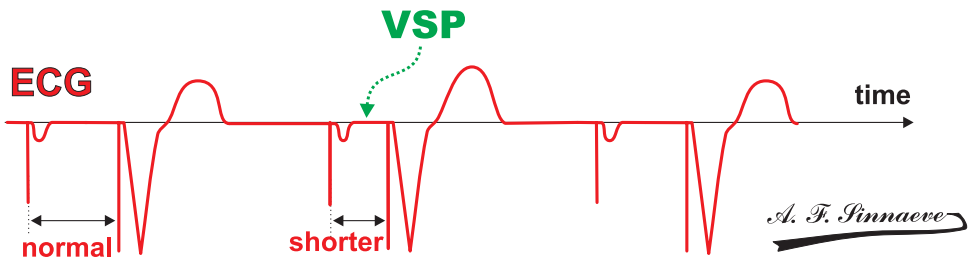
Abbreviations : AVI = atrioventricular interval ; AP = atrial pace ; VS = ventricular sense

THE ADDITION OF THE 6th CYCLE : VSP or VENTRICULAR SAFETY PACING

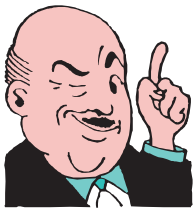
If this happens, the consequences of crosstalk can be prevented by adding a 6th timing cycle often called the VSP period in the first part of the AV delay. A signal sensed in the VSP will trigger a premature stimulus at the end of the VSP. In this way ventricular inhibition by crosstalk cannot occur....

The postatrial ventricular blanking period does not always prevent crosstalk !?

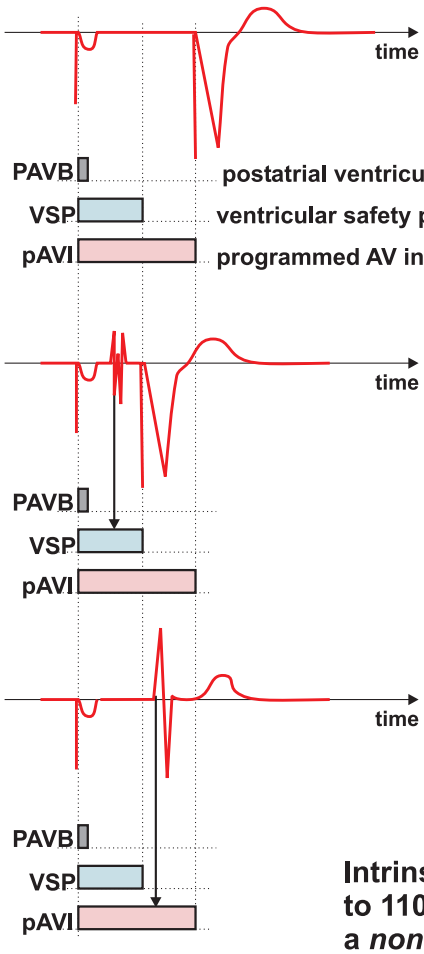
Let me show you !



VSP does not prevent crosstalk.
It simply prevents its consequences !



VENTRICULAR SAFETY PACING



No spontaneous conduction, no crosstalk, no interference : stimulation at the end of the programmed AV interval

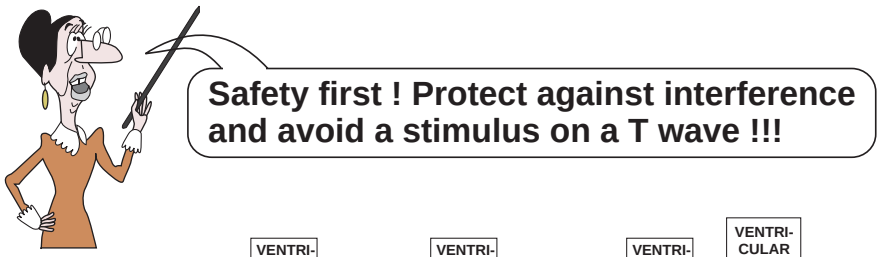
Interference (or early QRS) during the VSP window (beyond the PAVB) results in a committed ventricular stimulus at the end of that window and a characteristic shortening of the AV interval

Normal inhibition of the ventricular channel by a conducted QRS

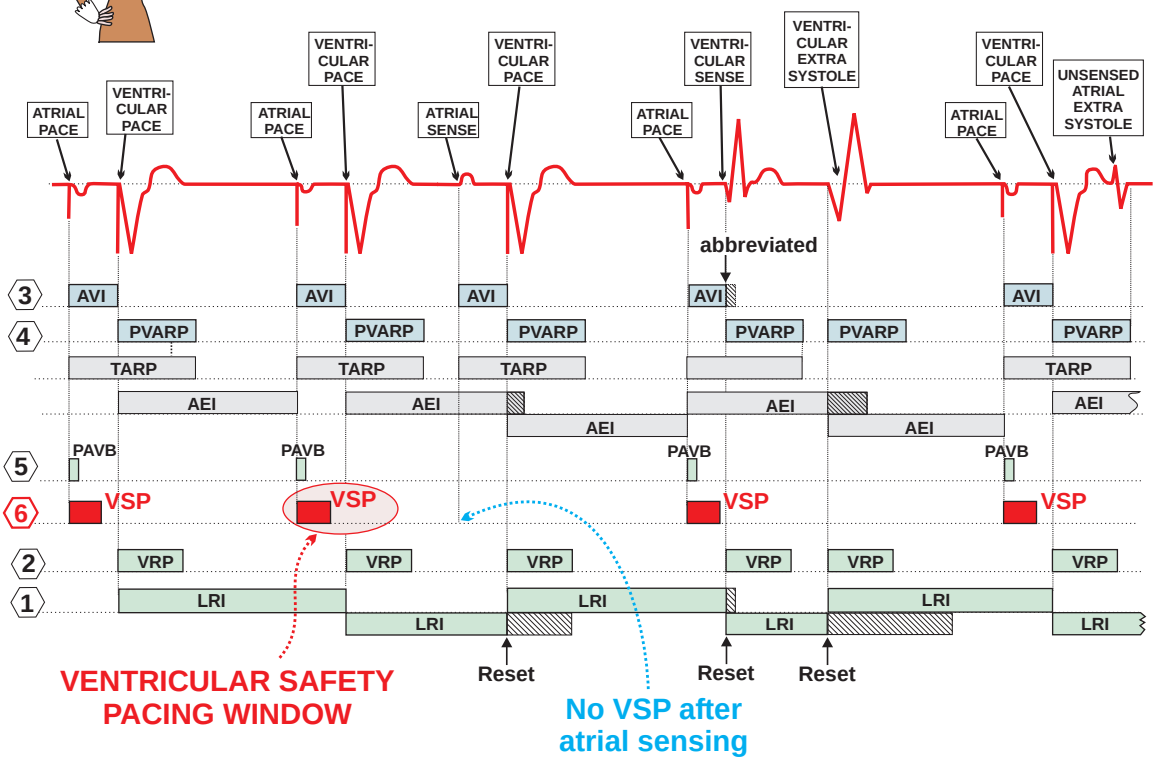
Intrinsic P-R intervals are usually longer than 100 to 110 ms, therefore the VSP window is often called a *non-physiologic AV delay*

A. F. Sinnaeve

ADDITION OF A SIXTH TIMING CYCLE TO A SIMPLE DDD PACEMAKER TO PREVENT THE CONSEQUENCES OF AV CROSSTALK



Safety first ! Protect against interference and avoid a stimulus on a T wave !!!

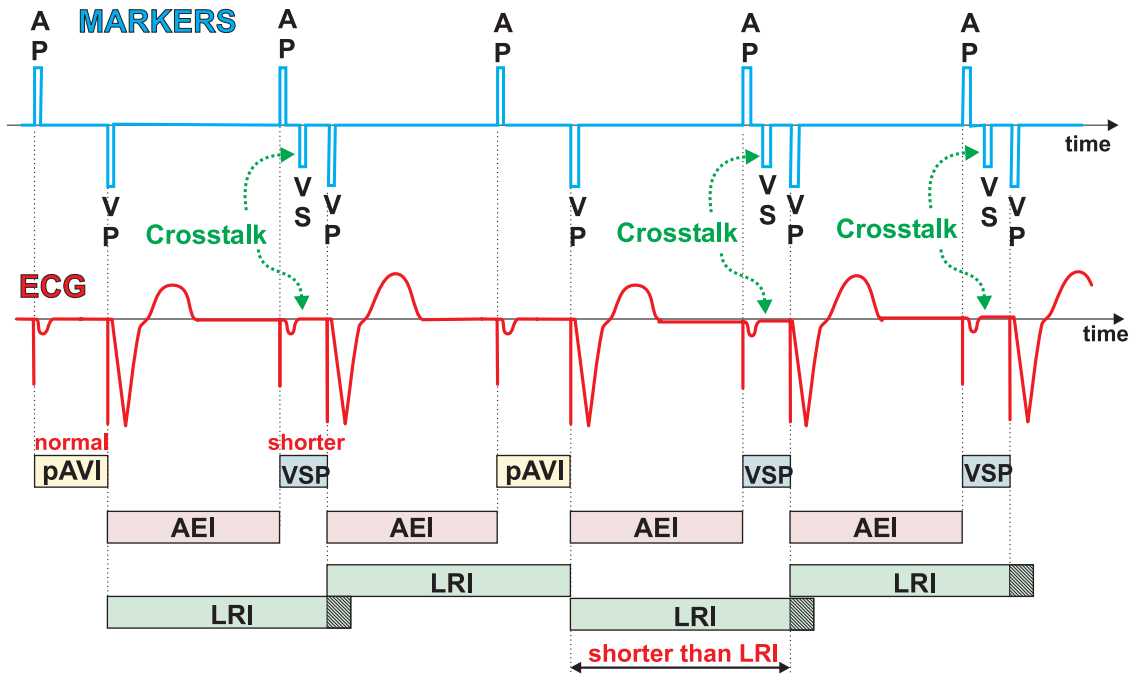


Ventricular Safety Pacing Window : by convention the VSP starts at the time of the atrial stimulus and its duration is usually 100 to 110 ms. The PAVB period, also activated by the atrial stimulus, occupies the initial portion of the VSP. Ventricular sensing cannot occur during this blanking period. Therefore ventricular sensing can occur in the VSP only after completion of the relatively short PAVB period.

ABBREVIATIONS : AVI = AV interval; PVARP = postventricular atrial refractory period; TARP = total atrial refractory period; AEI = atrial escape interval; PAVB = postatrial ventricular blanking; VSP = ventricular safety pacing window; VRP = ventricular refractory period; LRI = lower rate interval

A. F. Sinnaeve

ECG PATTERNS of VENTRICULAR SAFETY PACING
Intermittent crosstalk during DDD pacing



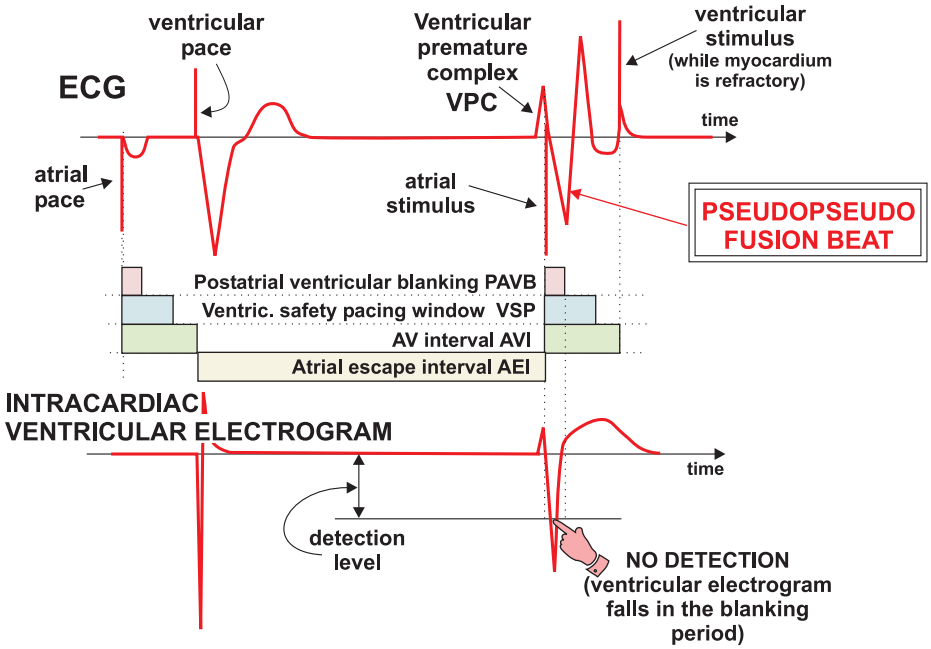
CONSEQUENCES OF CROSSTALK* :
> the paced AV delay (Ap-Vp) shorter than expected
> interval between consecutive ventricular stimuli shorter than expected
(* In a system with ventricular-based lower rate timing)

ABBREVIATIONS : Ap = atrial paced event; Vp = ventricular paced event; Vs = ventricular sensed event; pAVI = paced atrioventricular interval; VSP = ventricular safety pacing window; AEI = atrial escape interval; LRI = lower rate interval

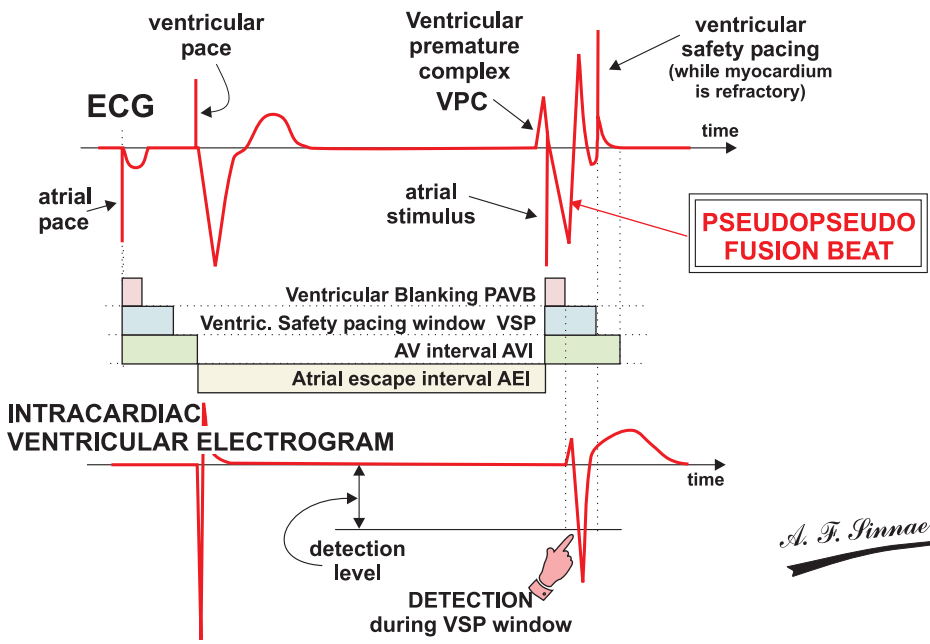
A. F. Sinnaeve

MANIFESTATIONS of VENTRICULAR SAFETY PACING with VENTRICULAR PREMATURE COMPLEXES

UNSENSED QRS COMPLEX



SENSED QRS COMPLEX



A. F. Sinnaeve

TESTING FOR AV CROSSTALK

ESTABLISH CONTINUAL ATRIAL AND VENTRICULAR PACING : AVOID COMPETITION

♣ Set the lower rate above the patient's own spontaneous rate

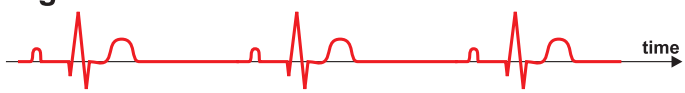
♠ Shorten the AV delay to less than the spontaneous PR interval

UNVEIL POTENTIAL PROBLEMS :

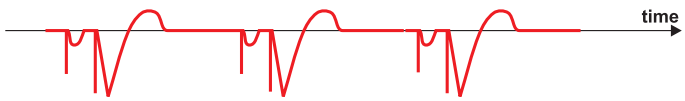
♦ Reprogram the atrial output to its maximal value (voltage and/or pulse duration)

♥ Reprogram the ventricular sensitivity to its most sensitive setting

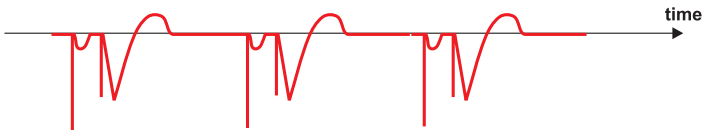
Patient's original ECG



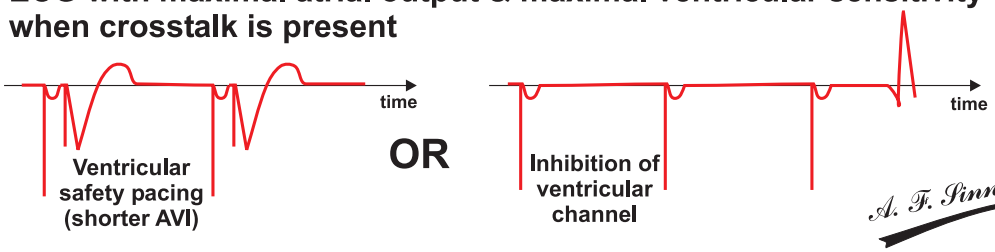
ECG after programming a faster rate & shorter AV interval



ECG with maximal atrial output & maximal ventricular sensitivity in the absence of crosstalk



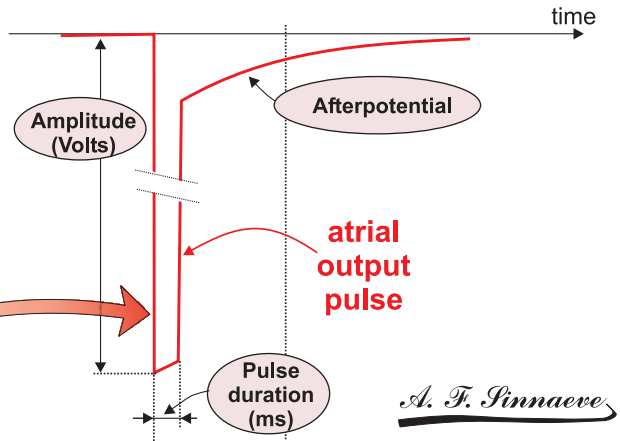
ECG with maximal atrial output & maximal ventricular sensitivity when crosstalk is present

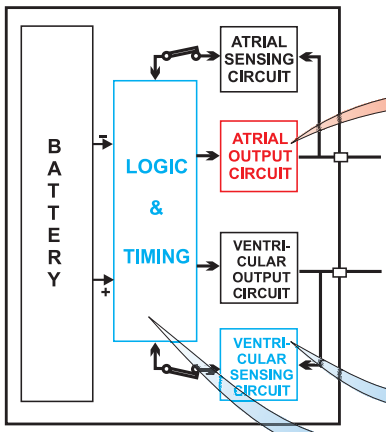


A. F. Sinnaeve

PREVENTION of AV CROSSTALK
(or SELF- INHIBITION)

Reduction of atrial output





A. F. Sinnaeve

Alteration of sensing

- Reduce ventricular sensitivity
- Blind the ventricular channel for an appropriate duration after the emission of the atrial stimulus (PAVB)

MANAGEMENT OF CROSSTALK

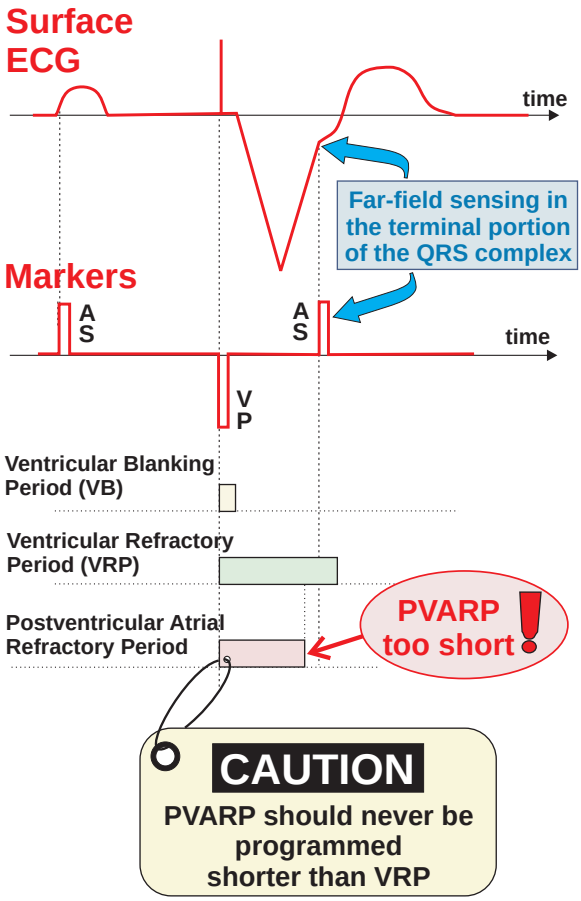
1. Crosstalk is best prevented by using bipolar dual-chamber devices.
2. If crosstalk is observed, decrease the atrial output (voltage and/or pulse duration).
3. Decrease the sensitivity of the ventricular channel (the numerical value - mV - of the sensitivity on the programmer will therefore increase).
4. Prolong the postatrial ventricular blanking period (PAVB). The PAVB lasts 10 to 60 ms and is programmable in most pacemakers !
5. Program ventricular safety pacing ON (if VSP is available).

SENSING OF THE TERMINAL PORTION OF THE QRS COMPLEX

If sufficient large, the far-field QRS complex may be picked up by the atrial channel if :

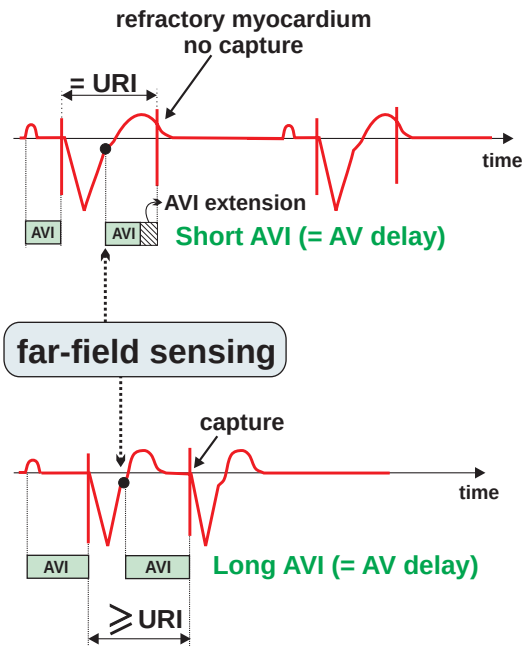
* the PVARP is relatively short

* the atrial sensitivity is high allowing sensing of the far-field signal



CAUTION

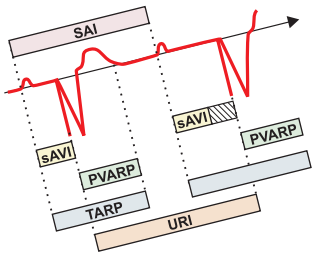
PVARP should never be programmed shorter than VRP

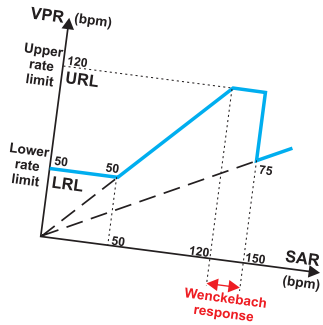


If the far-field QRS is sensed by the atrial channel, the pacemaker interprets it as a P wave, initiates an AV delay and triggers a ventricular stimulus at the completion of this AV delay (AVI).
The ventricular stimulus may or may not capture the ventricle according to its timing relative to the ventricular myocardial refractory period.

A. F. Sinnaeve

Abbreviations : AS = atrial sense ; VP = ventricular pace ; URI = upper rate interval ; PVARP = postventricular atrial refractory period ; VRP = ventricular rafractory period ; VB = ventricular blanking ; AVI = AV delay





DDD PACEMAKERS - UPPER RATE RESPONSE

* Tracking
* Fixed-ratio block 2 : 1
* Fixed-ratio block - Stress test
* Addition of 7th timing cycle to obtain upper rate response with Wenckebach block
* Wenckebach upper rate limitation
* How to ensure Wenckebach block
* Wenckebach upper rate response - part 1
* Wenckebach upper rate response - part 2
* Management of upper rate

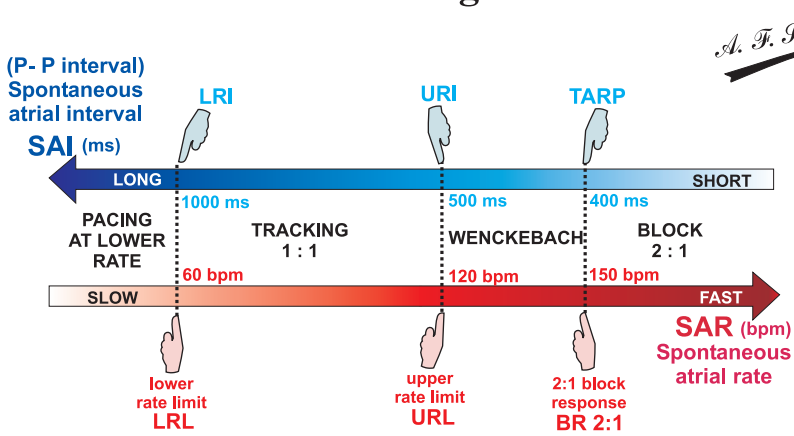
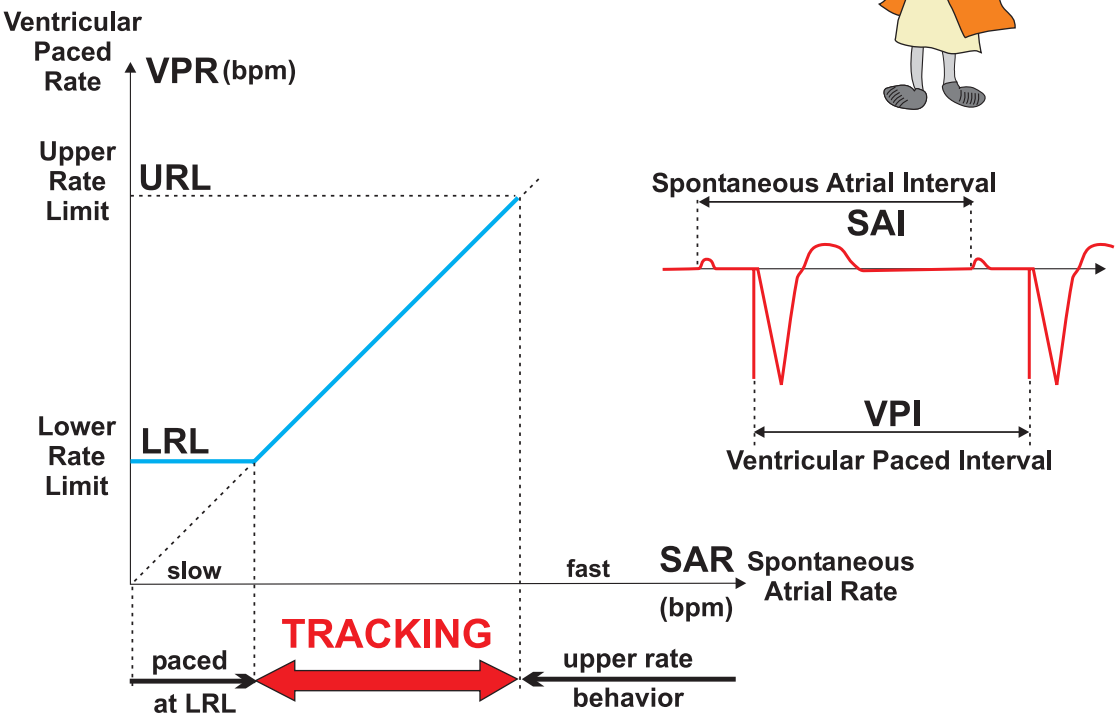
* Atrial premature complexes (APCs)
* APCs - More difficult
* Premature ventricular events - Definitions
* Functional atrial undersensing
* Apparent lack of atrial tracking



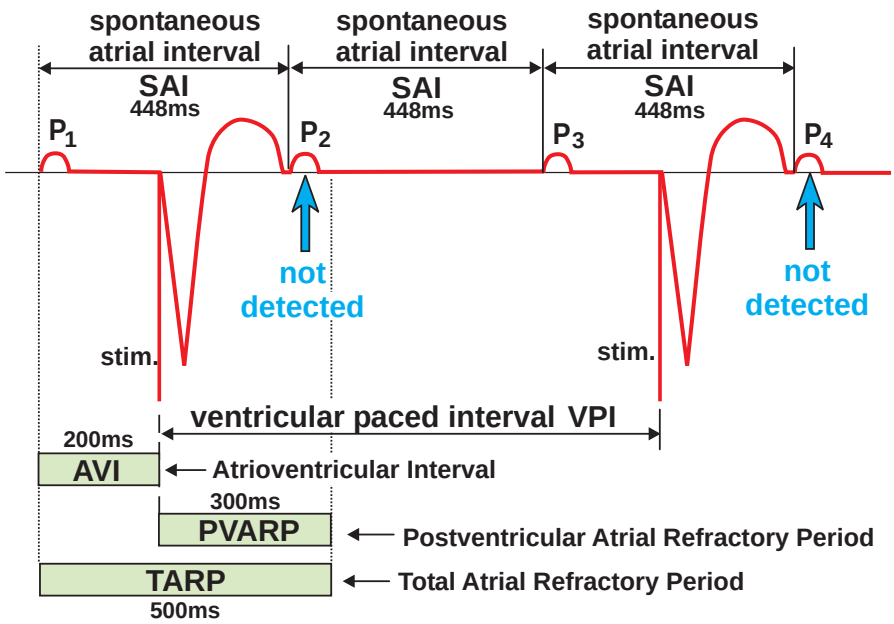
TRACKING is present when the ventricular paced rate follows the spontaneous atrial rate in a 1 : 1 way

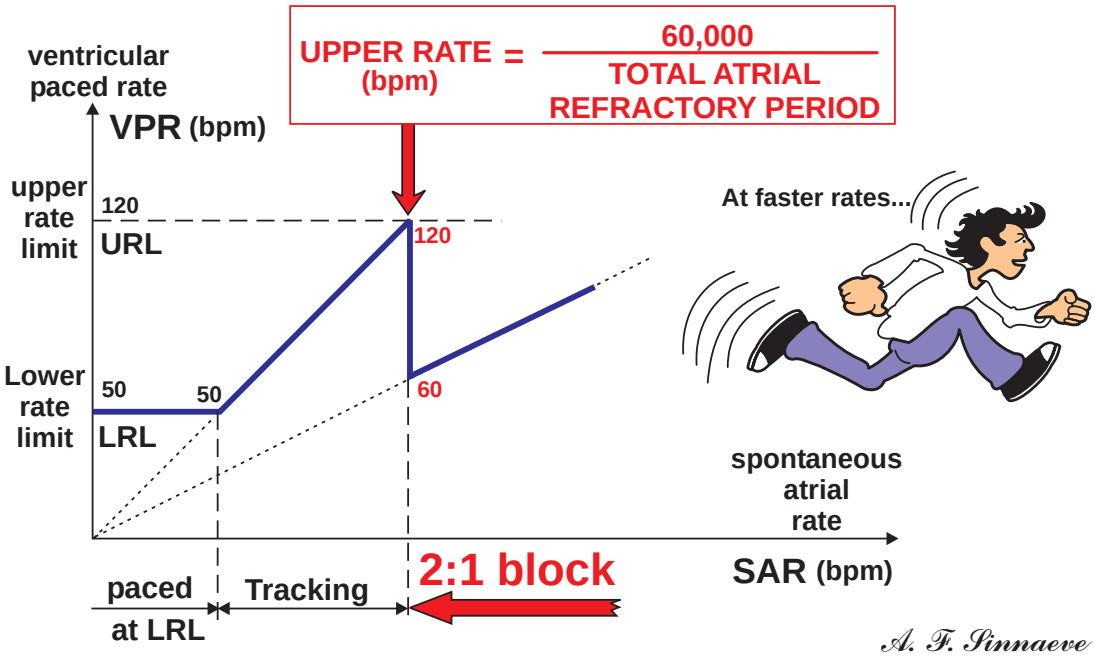


Spontaneous Atrial Rate (SAR in bpm)	=	$\frac{60{,}000}{\text{Spontaneous Atrial Interval (SAI in ms)}}$
Ventricular paced Rate (VPR in bpm)	=	$\frac{60{,}000}{\text{Ventricular Paced Interval (VPI in ms)}}$

A. F. Sinnaeve

FIXED RATIO BLOCK 2 :1

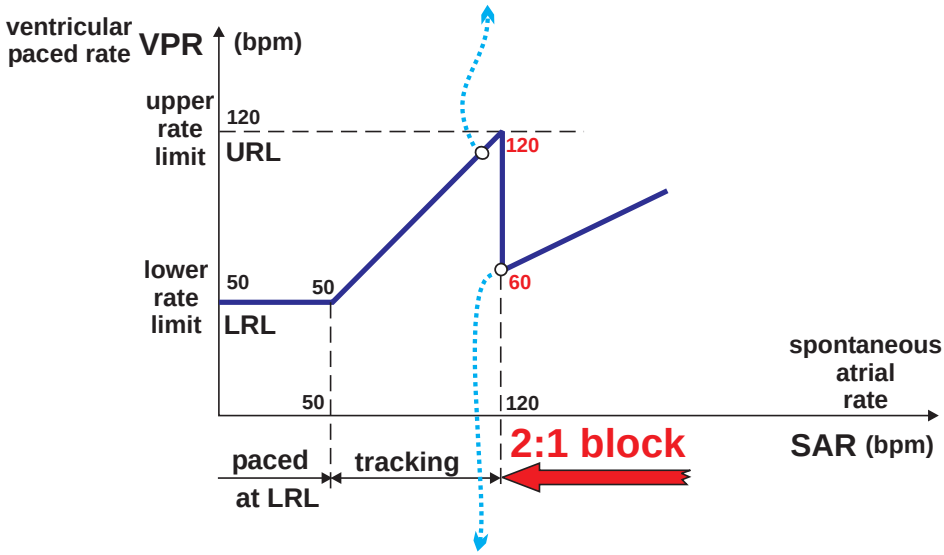


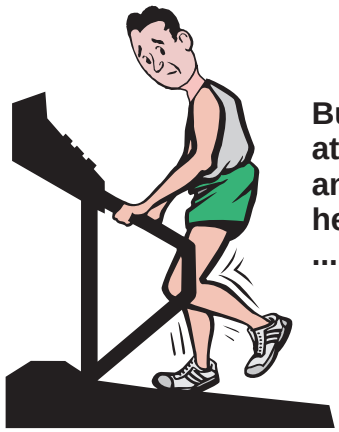


A. F. Sinnaeve

THE TREADMILL STRESS TEST

At an atrial rate of 115 bpm
and the same paced rate, he
still loved his physician....





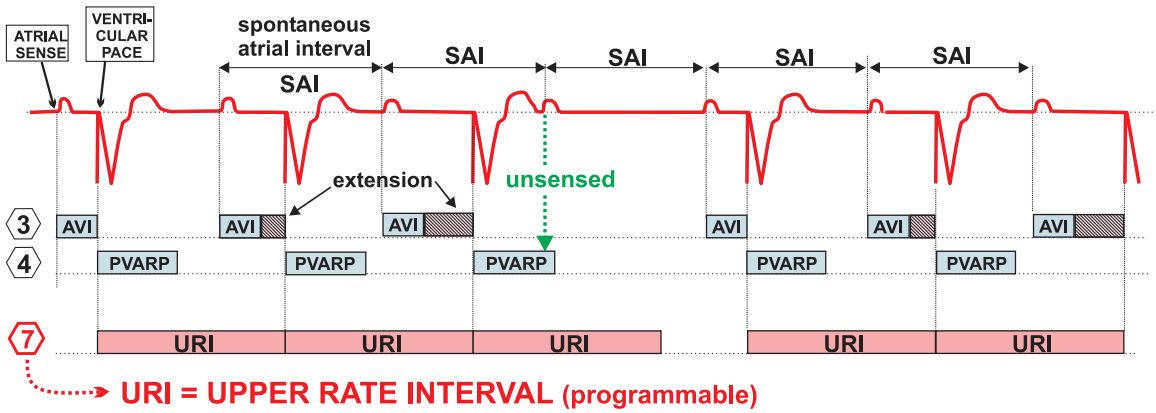
But...
at an atrial rate of 120 bpm
and a paced rate of 60 bpm
he felt himself very unhappy
.....

A. F. Sinnaeve

UPPER RATE LIMITATION

ADDITION OF A SEVENTH TIMING CYCLE TO A DDD PACEMAKER

Upper rate limitation by the abrupt development of 2:1 block should be prevented !

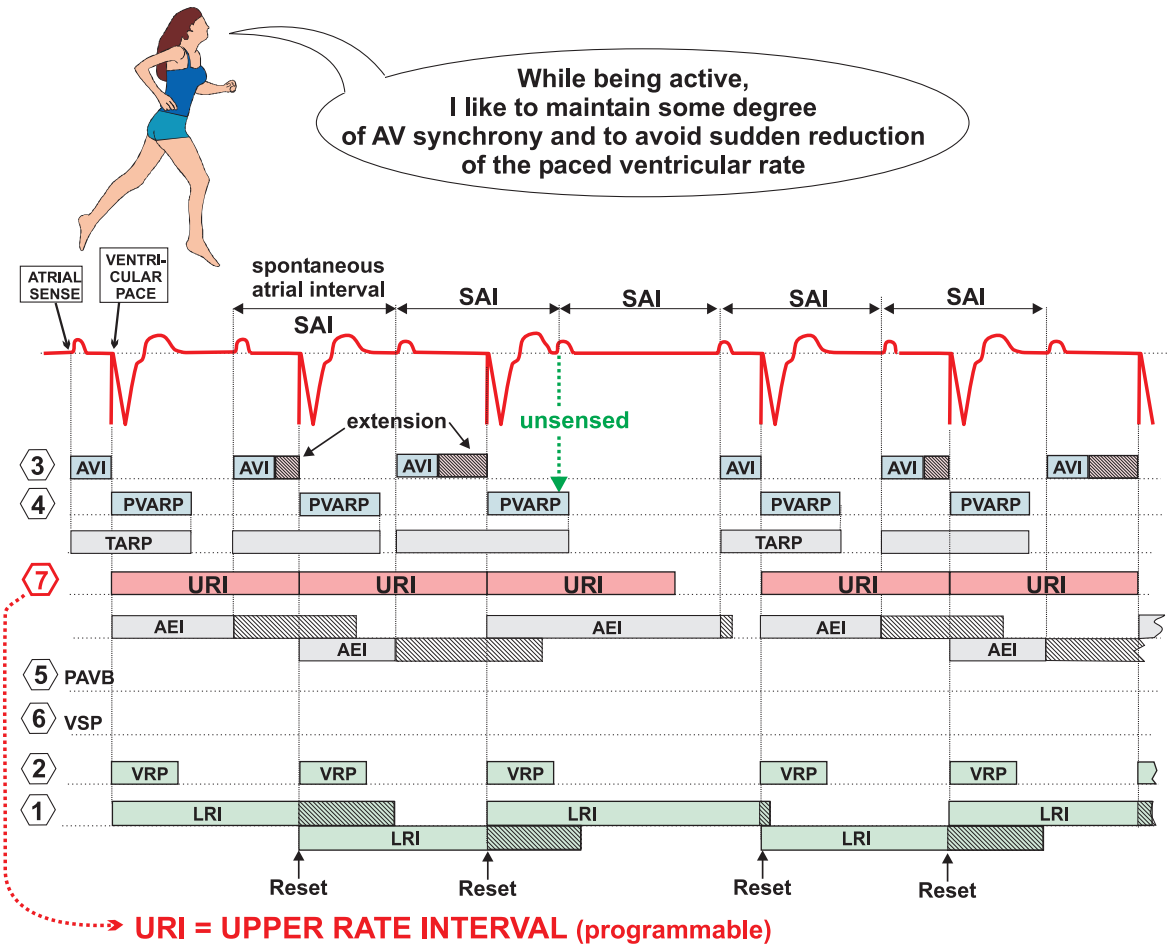


URI = UPPER RATE INTERVAL (programmable)

A Wenckebach upper rate response can only occur when the upper rate interval (URI) is programmed longer than the total atrial refractory period (TARP). The latter is the sum of the atrioventricular interval (AVI) and the postventricular atrial refractory period (PVARP) i.e. TARP = AVI + PVARP
If the upper rate interval (URI) equals the total atrial refractory period (TARP), no Wenckebach upper rate behavior is possible and the upper rate response will consist of 2:1 block.

A. F. Sinnaeve

ADDITION OF A SEVENTH TIMING CYCLE TO A DDD PACEMAKER TO AVOID ABRUPT 2:1 BLOCK



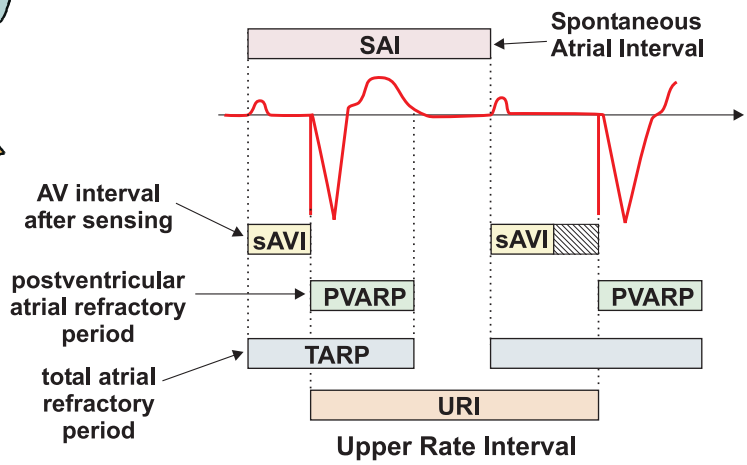
A pacemaker Wenckebach upper rate response can only occur if the pacemaker permits an upper rate interval (URI) longer than the pacemaker total atrial refractory period (TARP)

ABBREVIATIONS : AVI = AV interval; PVARP = postventricular atrial refractory period; TARP = total atrial refractory period; AEI = atrial escape interval; PAVB = postatrial ventricular blanking; VSP = ventricular safety pacing window; VRP = ventricular refractory period; LRI = lower rate interval

A. F. Sinnaeve

HOW TO ENSURE A WENCKEBACH UPPER RATE BEHAVIOR OF A PACEMAKER

A pacemaker Wenckebach upper rate response can only occur if the pacemaker permits an upper rate interval longer than the pacemaker total atrial refractory period



A shorter Total Atrial Refractory Period (TARP) pushes the 2 : 1 block rate to a higher level, thereby allowing the programming of a faster rate at which the Wenckebach response begins.
Manipulation of the sAVI and/or the PVARP allows the establishment of a faster upper rate by :

- **Programming a shorter basic AV Interval after sensing (sAVI)**
- **Shortening the sAVI with an increase in atrial rate**
- **Programming a shorter Postventricular Atrial Refractory Interval (PVARP)**
- **An adaptive PVARP shortening on exercise**

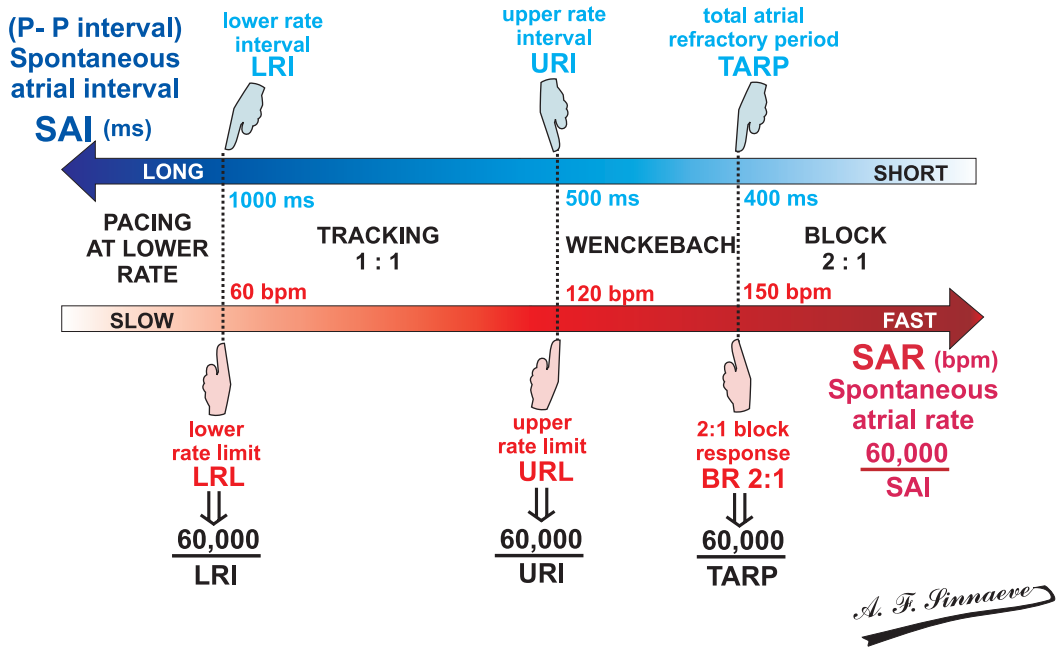
A. F. Sinnaeve

WENCKEBACH UPPER RATE RESPONSE

$$\text{RATE (bpm)} = \frac{60{,}000}{\text{INTERVAL (ms)}}$$

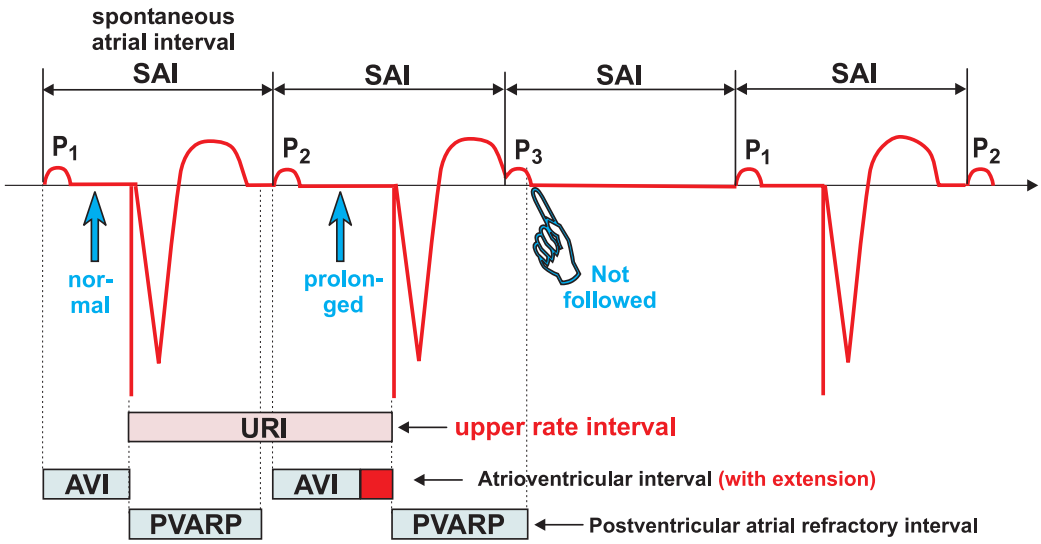
WENCKEBACH BEHAVIOR OCCURS IF :

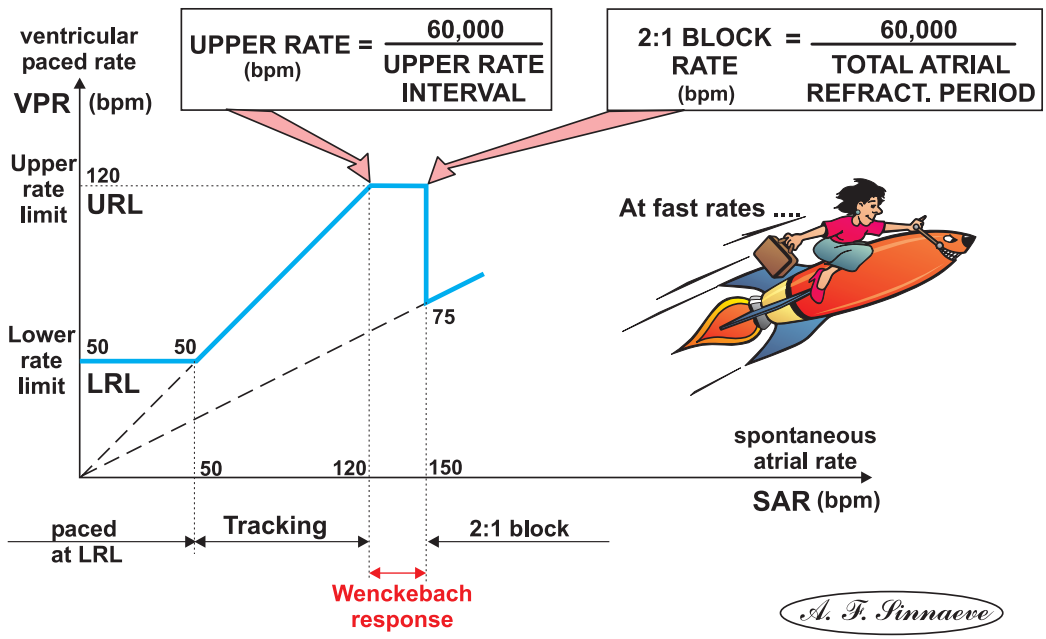
1. The upper rate interval (URI) is longer than the total atrial refractory period (TARP)
2. The spontaneous atrial interval (SAI) is longer than the total atrial refractory interval (TARP) but shorter than the upper rate interval (URI)



A. F. Sinnaeve

WENCKEBACH UPPER RATE RESPONSE





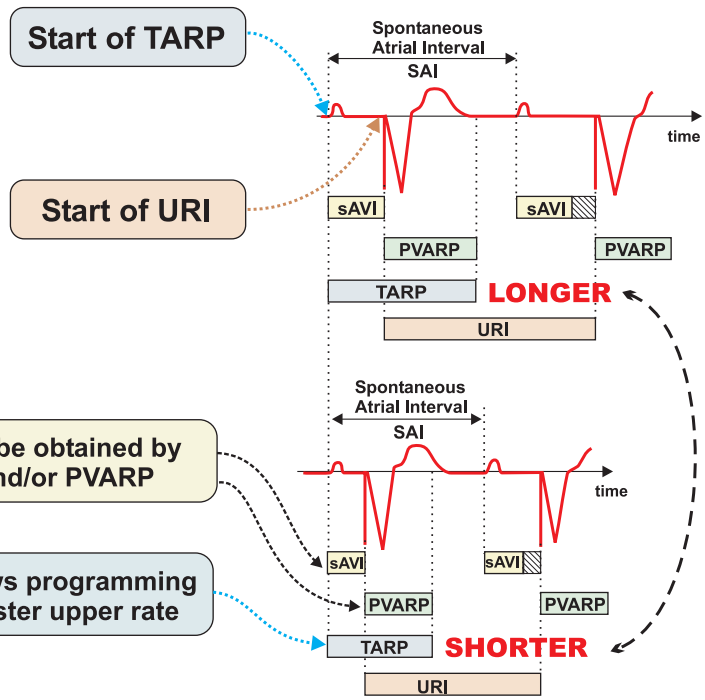
A. F. Sinnaeve

MANAGEMENT OF UPPER RATE ?

TARP DETERMINES THE RATE AT WHICH 2:1 BLOCK STARTS

WENCKEBACH UPPER RATE RESPONSE ONLY IF URI > TARP

WENCKEBACH UPPER RATE RESPONSE IMPOSSIBLE IF URI = TARP



* sAVI can be programmed shorter than pAVI at rest

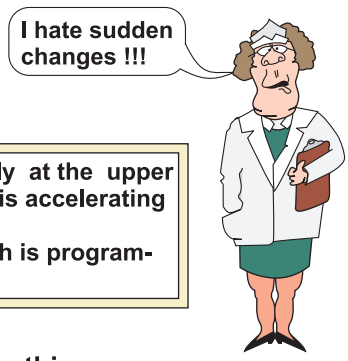
* sAVI and therefore TARP can shorten further if the pacemaker contains an algorithm to shorten the sAVI as the sensed atrial rate increases

* in some pacemakers the PVARP can also shorten on exercise

Abbreviations : sAVI = AV interval after sensing; SAI = spontaneous atrial interval; PVARP = postventricular atrial refractory period; TARP = total atrial refractory period; URI = upper rate interval;

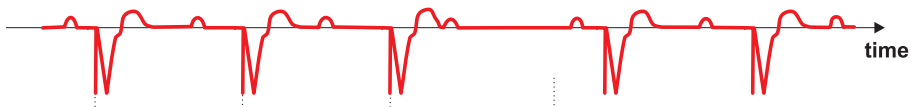
A. F. Sinnaeve

RATE SMOOTHING

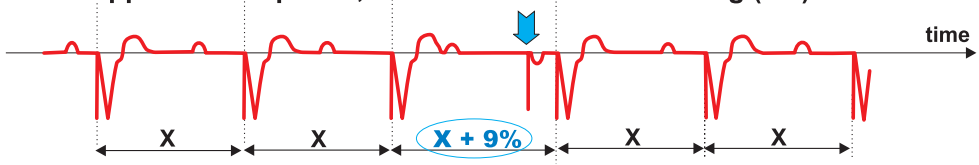


* Rate smoothing limits the changes in cycle length not only at the upper rate of DDD pacemakers, but also any time the sinus rate is accelerating or decelerating.
* The permitted maximum change in the pacing cycle length is programmable (3%,6%, 9%, 12%)

Wenckebach upper rate response without rate smoothing

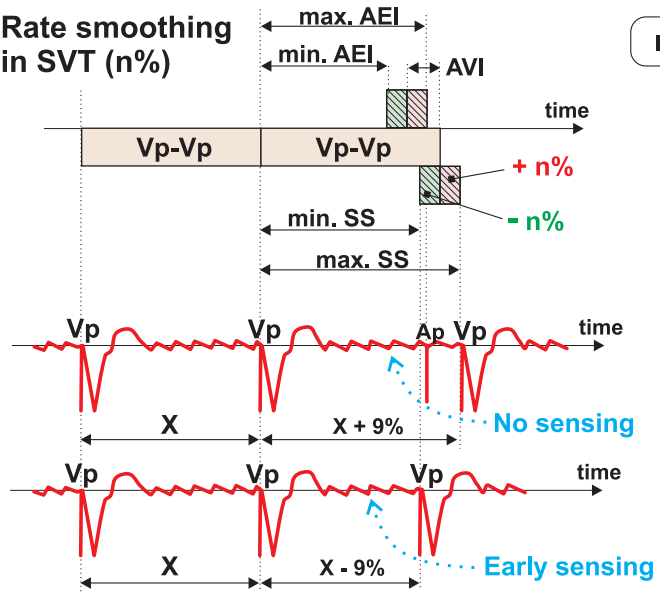


Same upper rate response, but with true rate smoothing (9%)



Note : A response similar to rate smoothing can also occur during rate-responsive DDDR pacing. With increased sensor input generated by exercise or activity, the pause at the end of a Wenckebach upper rate response can be attenuated or eliminated according to the prevailing sensor-driven interval. This response is potentially important in patients who do not tolerate the pauses in the Wenckebach upper rate response of DDD pacemakers

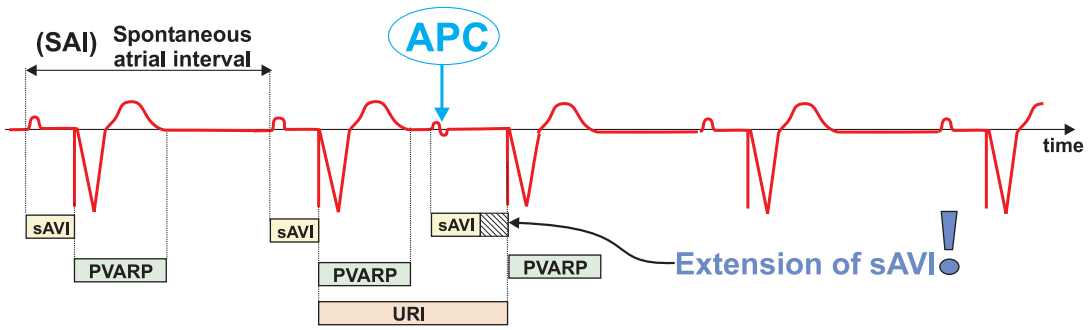
Rate smoothing in SVT (n%)



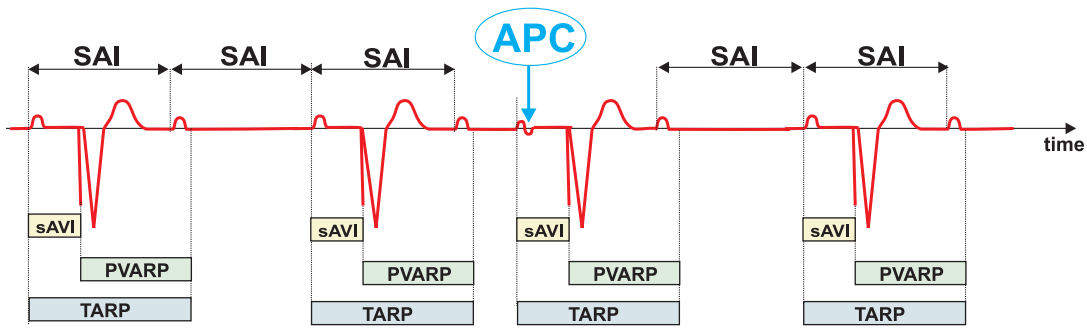
Abbreviations :
AEI = atrial escape interval ; AVI = AV delay
Ap = atrial pace ; Vp = ventricular pace ;
SS = interstimulus interval ; SVT = supra-ventriclar tachycardia

ATRIAL PREMATURE COMPLEXES AND UPPER RATE LIMITATION
* SOME EXAMPLES *

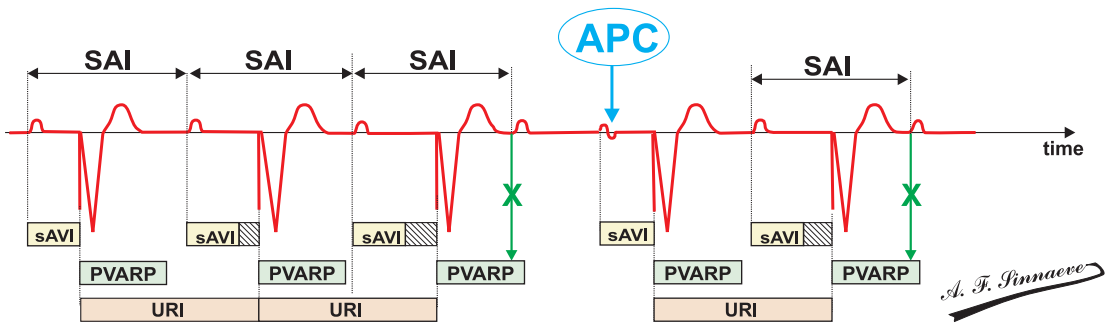
1. While tracking (LRI > SAI > URI)



2. During upper rate response with 2 : 1 block



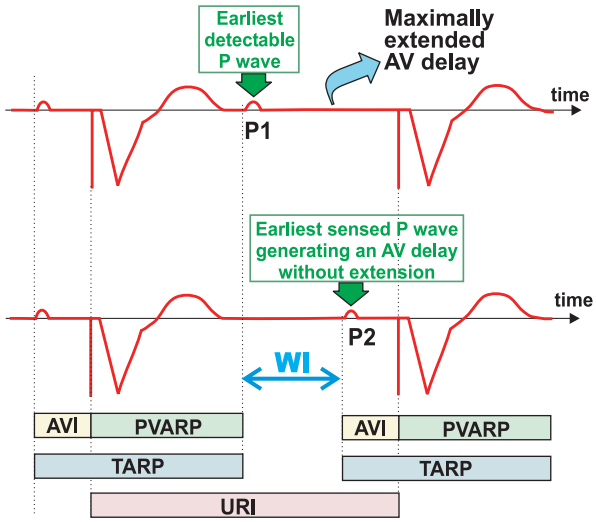
3. During upper rate response with Wenckebach behavior



Abbreviations : APC = atrial premature complex ; LRI = lower rate interval ; PVARP = postventricular atrial refractory period ; SAI = spontaneous atrial interval ; sAVI = AV delay after sensing ; TARP = total atrial refractory period ; URI = upper rate interval

ATRIAL PREMATURE COMPLEXES AND UPPER RATE LIMITATION
DDD pacemaker with URI > TARP

The AV delay initiated by an APC depends on its timing in the pacemaker cycle ! Unexplained upper rate limitation is often due to an APC !!!



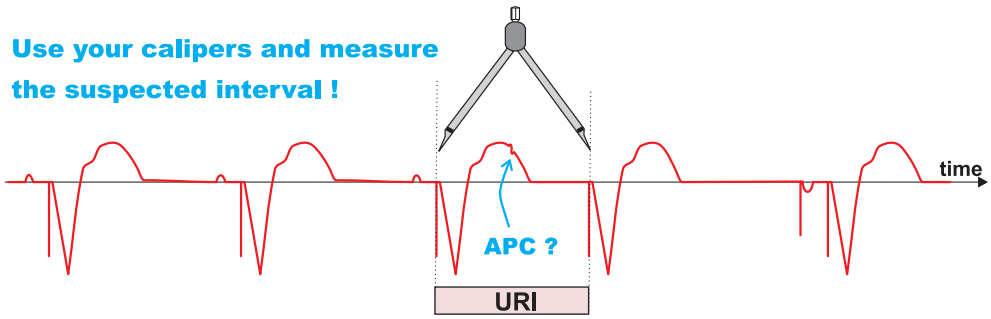
The Wenckebach interval (WI) is equal to the longest prolongation of the AV delay. It is therefore equal to :

$$WI = URI - (AVI + PVARP)$$

$$WI = URI - TARP$$

A P wave (P1) immediately after PVARP termination will exhibit the longest interval (AVI +WI) to conform to the constancy of the URI. A P wave (P2) just beyond the WI will initiate an AV interval equal to the programmed value. P waves in the WI will exhibit varying degrees of AV prolongation to conform to the URI.

Use your calipers and measure the suspected interval !



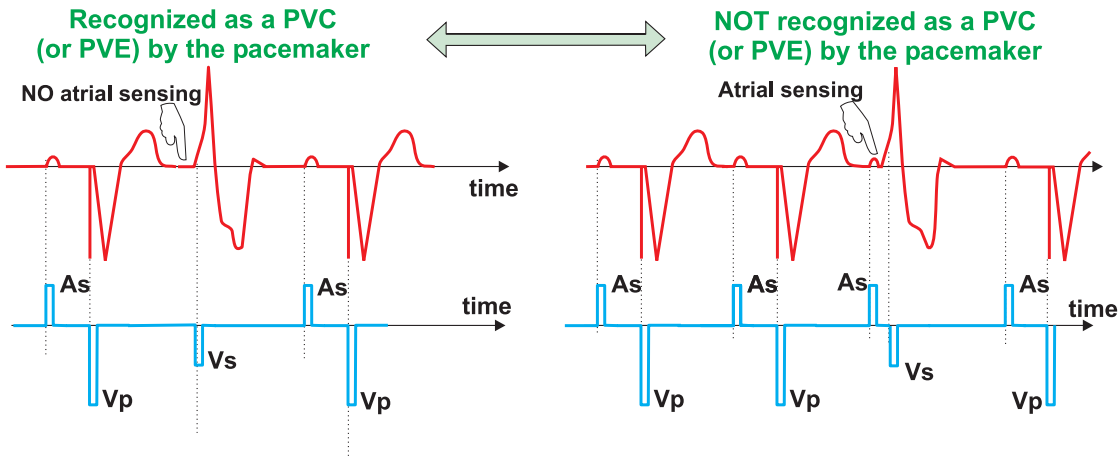
The URI can be identified on the ECG by moving calipers from the early ventricular stimulus back to the previous ventricular event. If this measured interval equals URI, it provides proof that an atrial sensed event occurred between the two ventricular events bracketing the URI. By far the most likely cause is an APC or less commonly a retrograde P wave as an isolated event. Far-field T wave sensing by the atrial channel is very rare, even at very high atrial sensitivity.

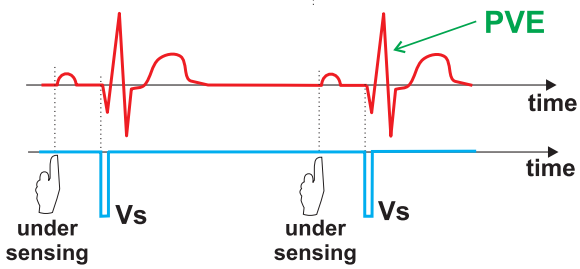
Abbreviations : APC = atrial premature complex; AVI = AV interval or AV delay; PVARP = postventricular atrial refractory period; TARP = total atrial refractory period; URI = upper rate interval; WI = Wenckebach interval

A. F. Sinnaeve

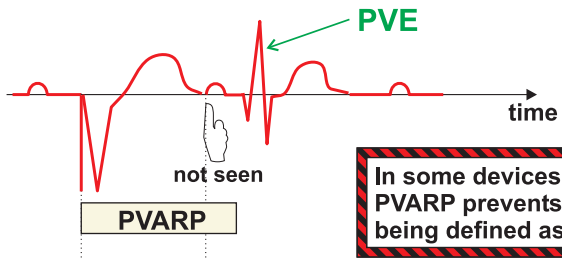
ABOUT PREMATURE VENTRICULAR EVENTS (PVE)

DEFINITION : a PVE is a sensed R wave that is not preceded by an atrial event, paced or sensed, according to the pacemaker.
Thus a pacemaker-defined PVE terminates an interventricular interval without an intervening atrial event.
A pacemaker's PVE is not necessarily the same event as a clinician's PVC !





Atrial undersensing with spontaneous AV conduction.
Since the P wave is not seen by the pacemaker, the R wave is stored as a PVC.



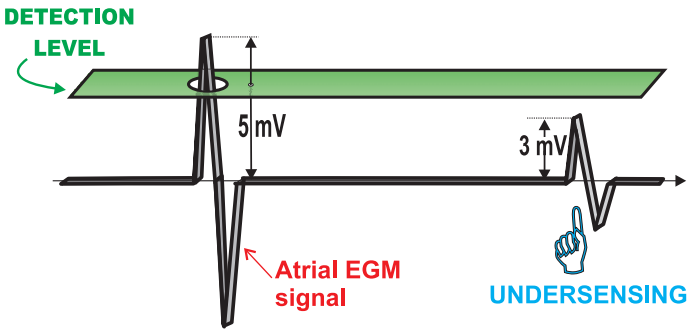
Functional atrial undersensing.
The P wave is not seen because it falls within the refractory period. The subsequent R wave is stored as a PVC

In some devices, an atrial refractory sensed event in the PVARP prevents a succeeding ventricular event from being defined as a pacemaker-PVE

Abbreviations : PVARP = postventricular atrial refractory period; PVE = premature ventricular event; PVC = premature ventricular complex ; As = atrial sensed event; Ap = atrial paced event; Vp = ventricular paced event; Vs = ventricular sensed event

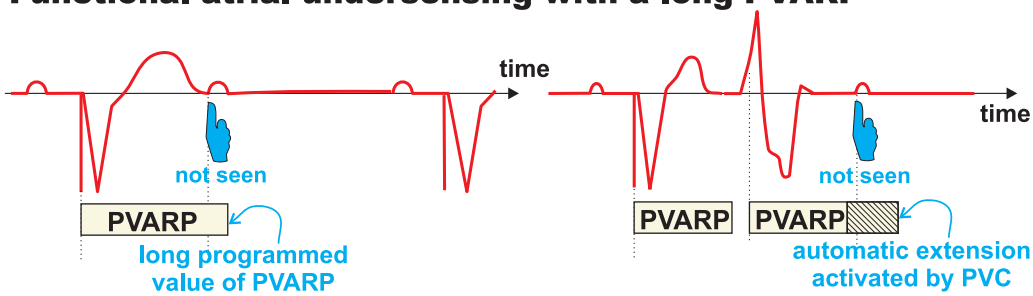
A. F. Sinnaeve

FUNCTIONAL ATRIAL UNDERSENSING

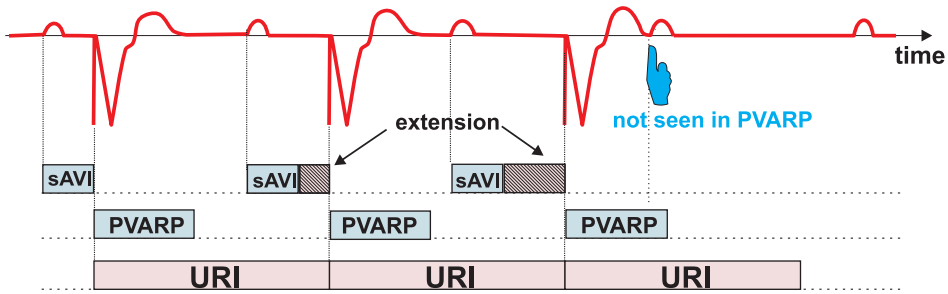


REMEMBER :
true atrial undersensing occurs when the amplitude is too small

Functional atrial undersensing with a long PVARP



Apparent or functional atrial undersensing due to upper rate limitation (displacement of the P wave in the PVARP as a function of the atrial rate).



CAUTION

A. F. Sinnaeve

Remember that automatic PVARP extension after a pacemaker-defined PVC may cause functional atrial undersensing even when the basic PVARP is relatively short.

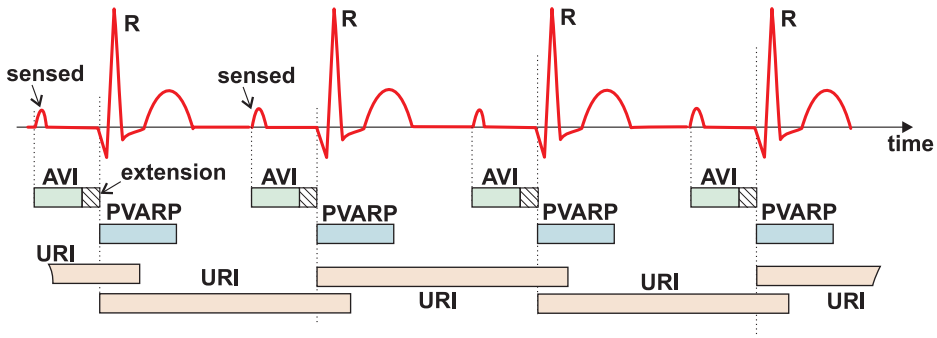
Abbreviations : EGM = electrogram; mV = millivolt; PVC = premature ventricular complex; PVARP = postventricular atrial refractory period; sAVI = AV delay after a sensed atrial event; URI = upper rate interval

Sometimes we see a prolongation of the interval between atrial-sensed and ventricular-sensed events beyond the programmed AV interval, while there is no true atrial undersensing because the amplitude of the atrial electrogram is adequate for atrial sensing !!!

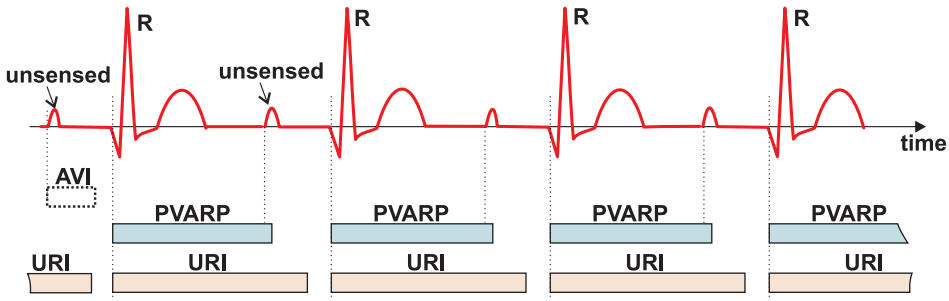
APPARENT LACK OF ATRIAL TRACKING

1 Spontaneous R-R interval shorter than ventricular upper rate interval (URI)

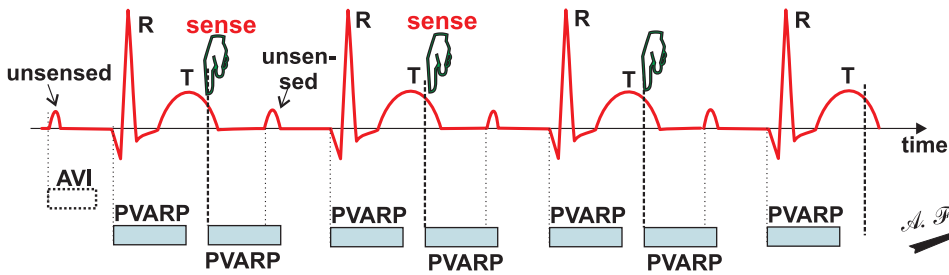
(Repetitive pre-empted Wenckebach upper rate response)



2 Excessively long PVARP prevents the detection of P waves (at relatively fast spontaneous atrial rate)

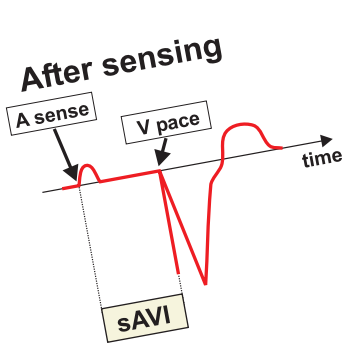


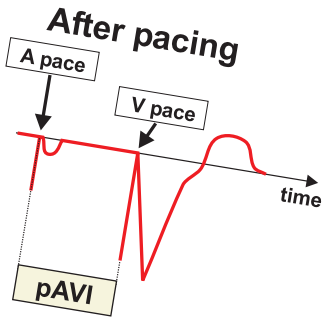
3 Ventricular oversensing (T wave sensing) starts a new PVARP thus preventing normal P wave sensing



A. F. Sinnaeve

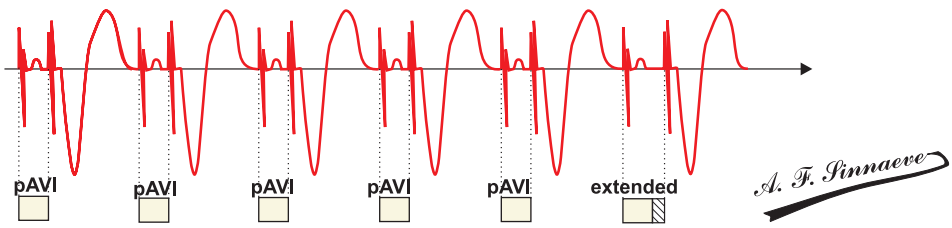
Abbreviations : AVI = programmed AV delay; PVARP = postventricular atrial refractory period; URI = upper rate interval





ATRIOVENTRICULAR INTERVAL (AVI)

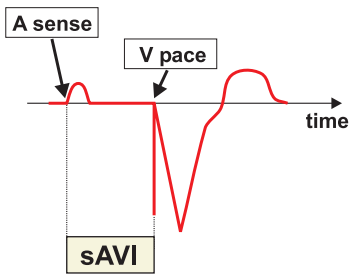
* AV delay - paced and sensed
* Rate-adaptive AV delay
* How to program the AV delay ?
* AV search hysteresis



The AV DELAY or ATRIOVENTRICULAR INTERVAL (AVI)

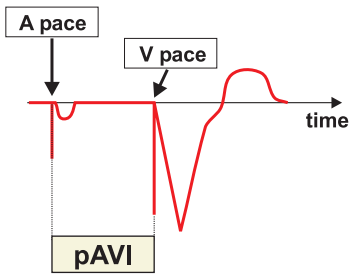
AVI is the interval between an atrial event (either sensed or paced) and the scheduled delivery of a ventricular stimulus

After sensing



sAVI starts with an atrial sensed event

After pacing



pAVI starts with an atrial stimulus

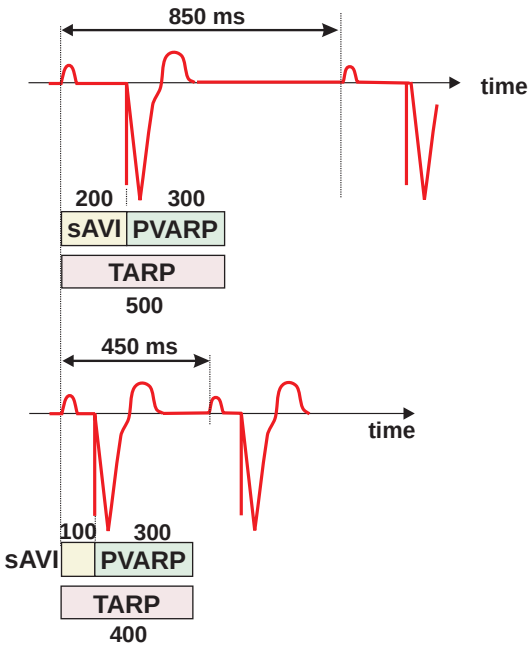
- Separate AV intervals for paced and sensed atrial events are available
- **Usually sAVI < pAVI**
  typically sAVI is 30-50 ms shorter than pAVI
- The AV intervals may be programmed to fixed values or (optionally) rate-adaptive i.e. shortening with increasing atrial rates

A. F. Sinnaeve

THE RATE-ADAPTIVE AV INTERVAL

My AV delay is normal or physiologic.
It shortens whenever I exercise !

The rate-adaptive AV interval mimics the physiologic response of the heart



RELATIVELY SLOW ATRIAL RATE
→ LONGER AV DELAY

Spontaneous atrial interval SAI = 850 ms

Spontaneous atrial rate SAR = 71 bpm

Sensed atrioventricular interval sAVI = 200 ms

FASTER ATRIAL RATE
→ SHORTER AV DELAY

Spontaneous atrial interval SAI = 450 ms

Spontaneous atrial rate SAR = 133 bpm

Sensed atrioventricular interval sAVI = 100 ms

THE PROGRAMMER MAY CHANGE

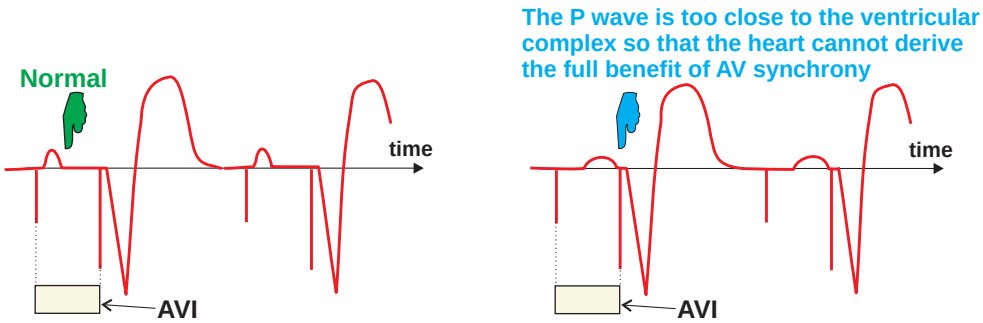
- *** the maximum value of sAVI**
- *** the minimum value of sAVI**
- *** the value of the gradual decrement of sAVI between these 2 rates**
- *** the range of rates where the change in the sAVI occurs**

pAVI can also shorten according to the input of a nonatrial sensor that reflects increased activity

A. F. Sinnaeve

HOW TO OBTAIN AN OPTIMAL AV DELAY ?

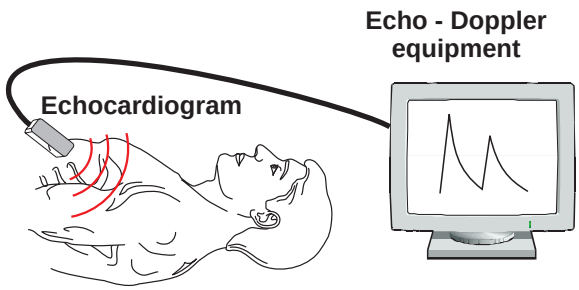
* In healthy individuals at rest, the optimal basic PR or AV interval normally lies between 120 and 210 ms
* The optimal value varies greatly from one patient to another as a function of several physiologic and pathologic factors including age (shorter in young people)
* Optimization of the AV delay (AVI) is needed at rest and exercise

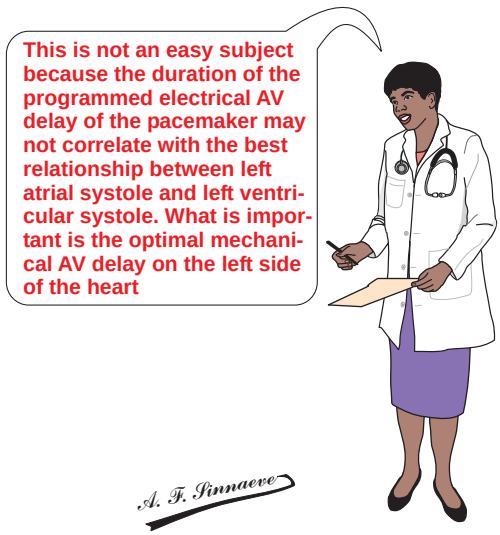


The electrical AV delay on the right side of the heart controlled by programming the pacemaker must produce an appropriate mechanical AV delay on the left side of the heart to preserve the atrial contribution to the cardiac output and optimize left ventricular function !!!

The optimal AV delay cannot be determined from the surface ECG !!!

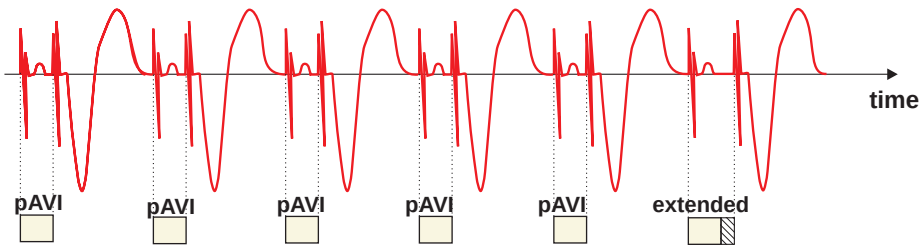
Doppler echocardiography is required to determine the optimal AV delay that produces the best stroke volume and cardiac output for each individual





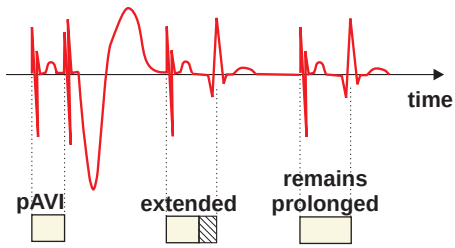
AV DELAY HYSTERESIS

Facilitation of normal AV conduction to promote normal ventricular depolarization

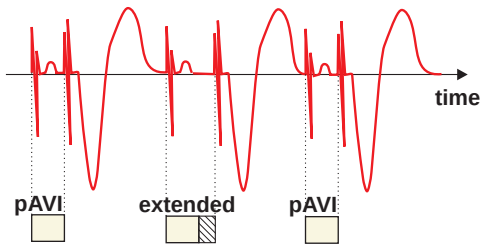


After "n" consecutive ventricular paced complexes, the AV delay is prolonged for "1" cycle

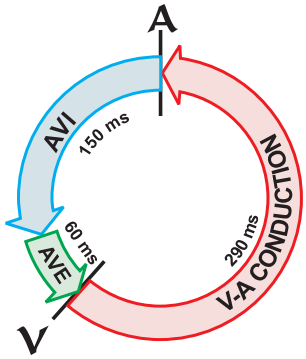
1 **If an intrinsic ventricular event is sensed, the AV delay remains prolonged**



2 **If no intrinsic ventricular event is sensed, the AV delay returns to the programmed value**

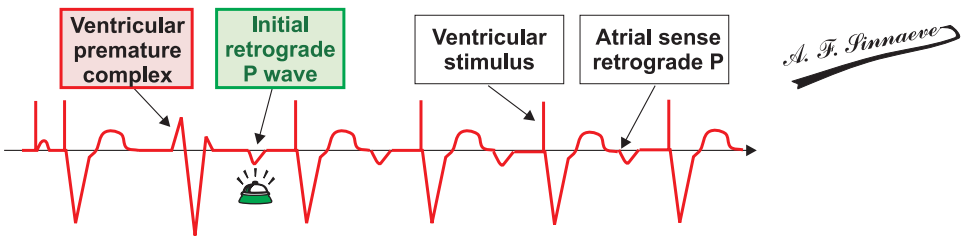


Abbreviations : AV = atrio-ventricular ; pAVI = paced atrioventricular interval

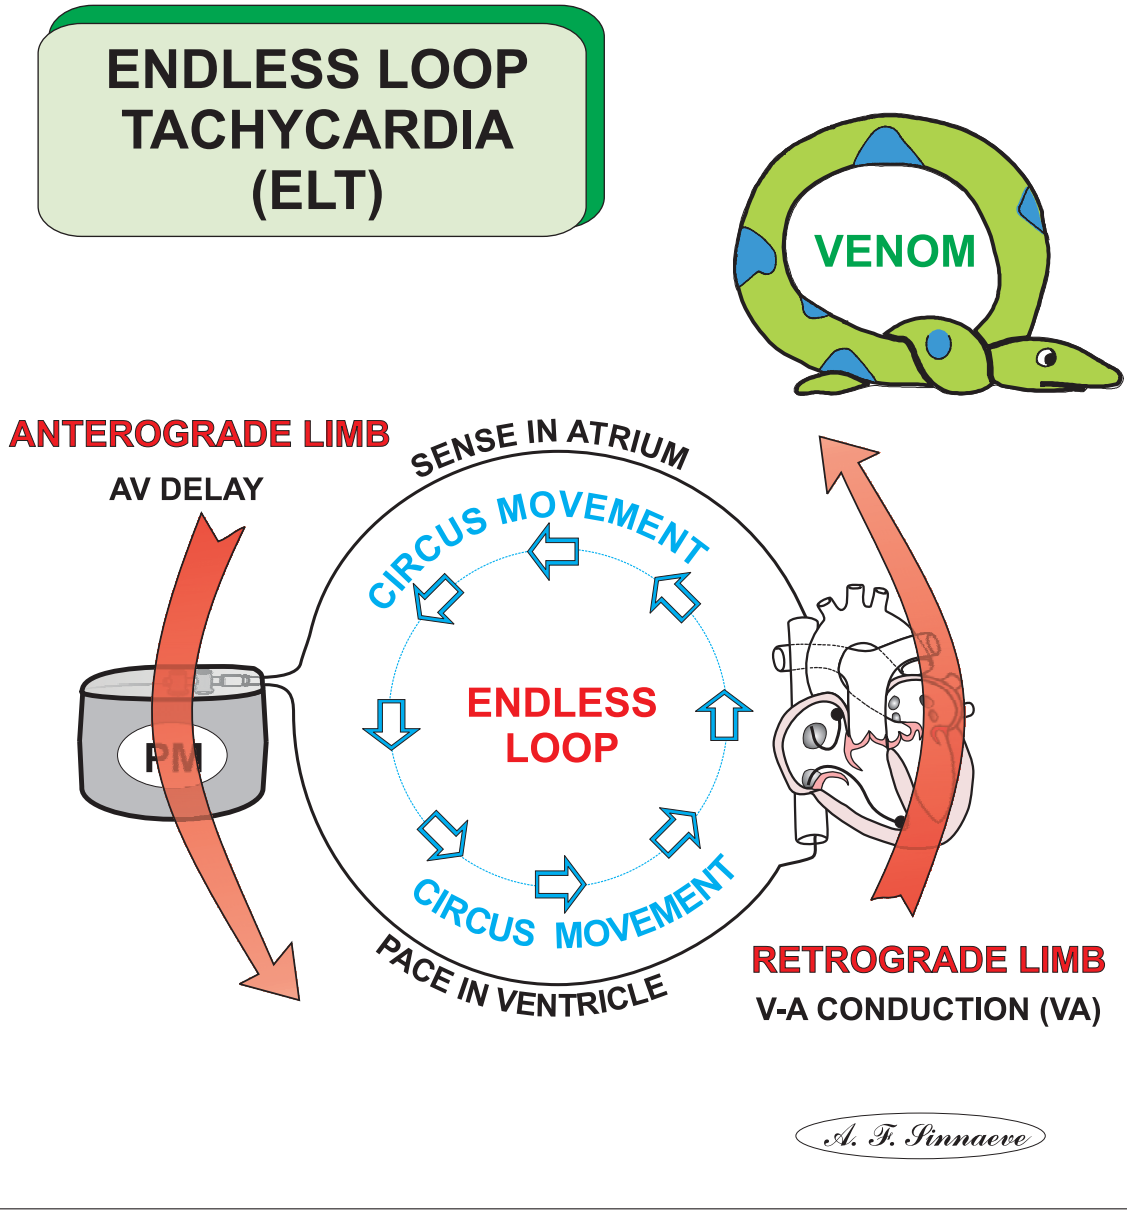


RETROGRADE VENTRICULOATRIAL SYNCHRONY IN DUAL CHAMBER PACEMAKERS

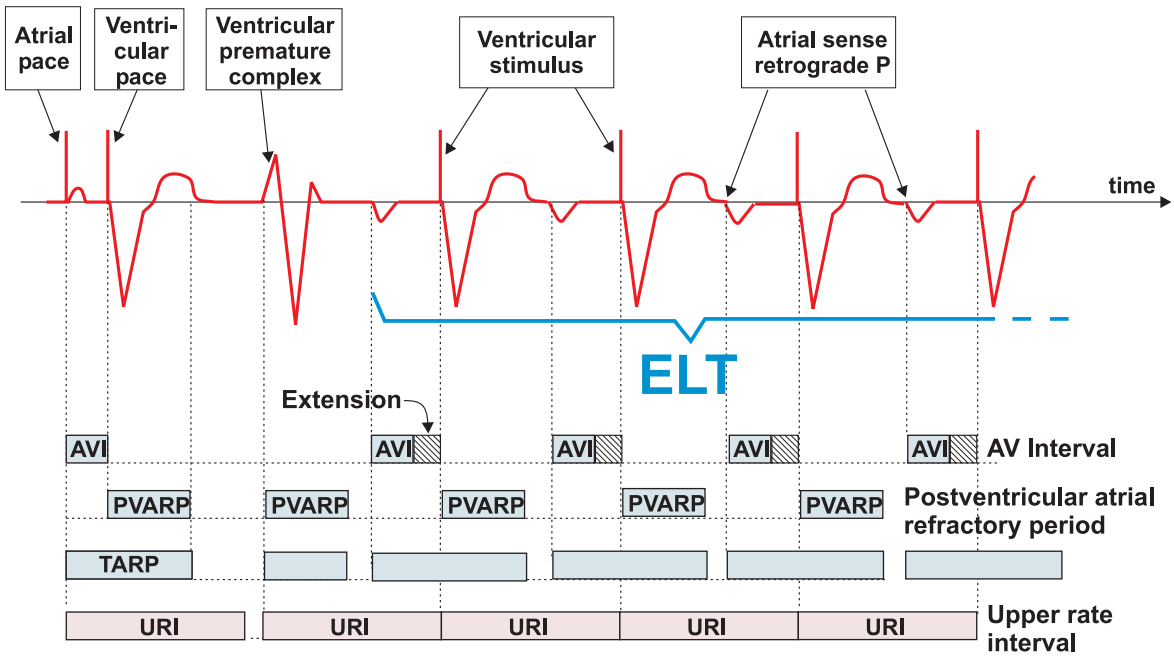
* Mechanism of endless loop tachycardia (ELT)
* ECG of ELT
* ELT : precipitating factors
* Rate of ELTs
* Testing for retrograde ventriculoatrial (VA) conduction
* Far-field ELT
* ECG of repetitive nonreentrant VA synchrony (RNRVAS)
* RNRVAS : prevention & treatment
* The cousins : ELT and RNRVAS
* Algorithms for ELT prevention - part 1
* Algorithms for ELT prevention - part 2
* Algorithms for ELT prevention - part 3



ENDLESS LOOP TACHYCARDIA (ELT)



DDD PACEMAKER & ENDLESS LOOP TACHYCARDIA



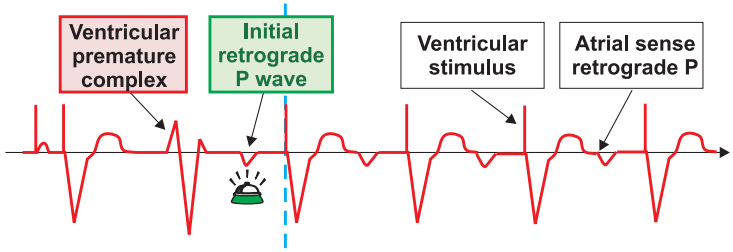
Endless loop tachycardia often occurs at the upper rate. In such a case as the programmed upper rate interval (URI) is longer than the total atrial refractory interval (TARP), the AV delay is extended to conform to the upper rate interval (URI)

Abbreviations : AVI = atrioventricular interval ; AVE = extension of AVI ; ELT = endless loop tachycardia ; PVARP = postventricular atrial refractory period ; TARP = total atrial refractory period ; URI = upper rate interval

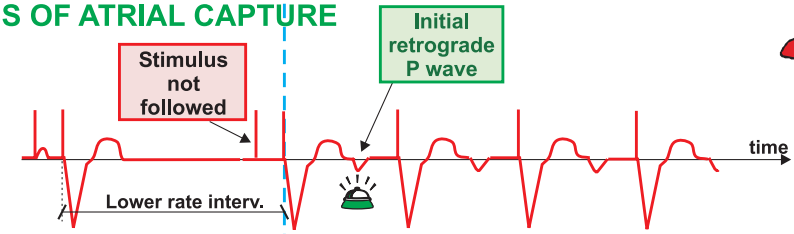
A. F. Sinnaeve

ENDLESS LOOP TACHYCARDIA PRECIPITATING FACTORS

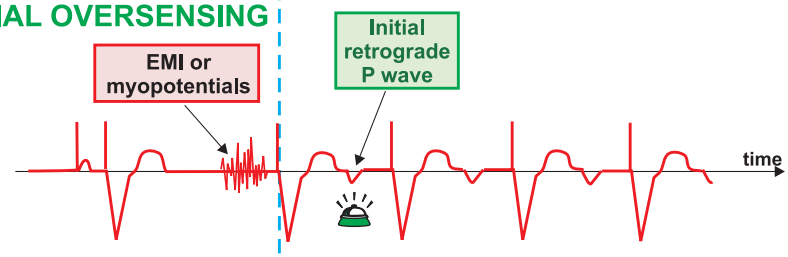
1 VENTRICULAR EXTRASYSTOLES



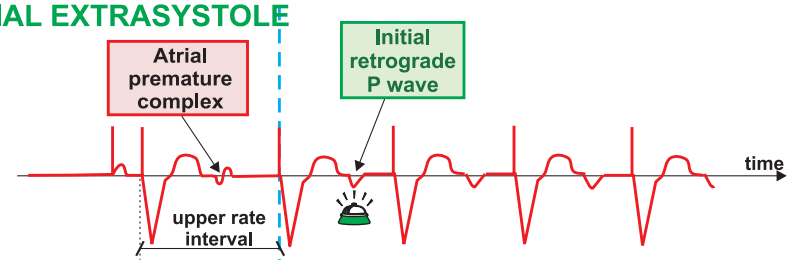
2 LOSS OF ATRIAL CAPTURE



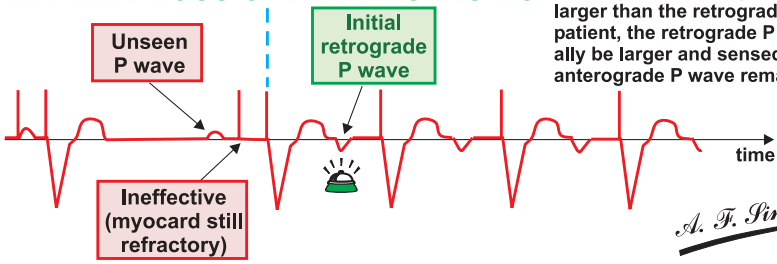
3 ATRIAL OVERSENSING



4 ATRIAL EXTRASYSTOLE



5 INTERMITTENT LOSS OF ATRIAL SENSING

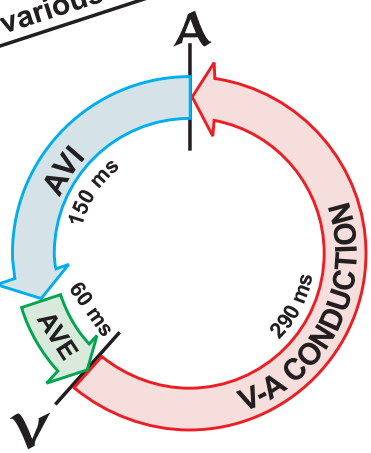


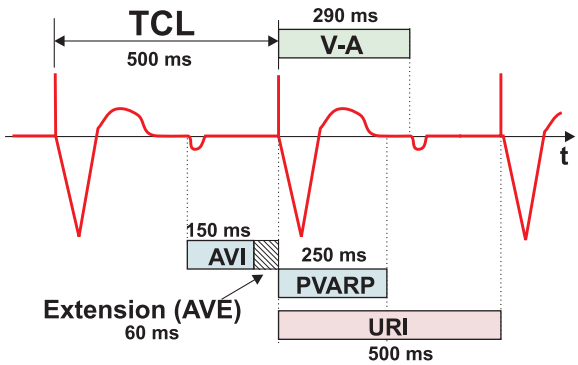
Although the anterograde P wave is usually larger than the retrograde P wave in a given patient, the retrograde P wave may occasionally be larger and sensed when the smaller anterograde P wave remains unsensed.

A. F. Sinnaeve

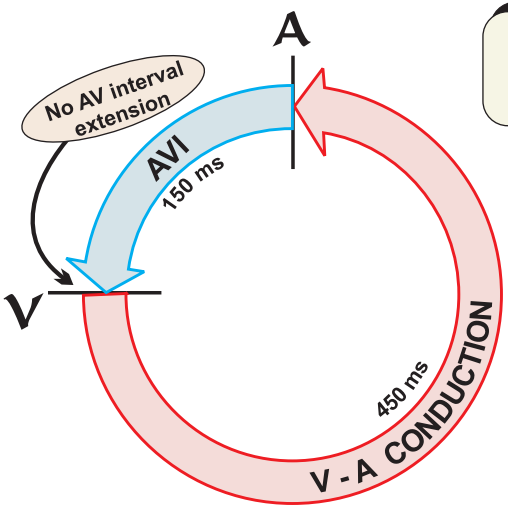
Abbreviations : EMI = electromagnetic interference ; Myopotentials = random signals (noise) caused by the action of some muscles ; myocard = myocardium or cardiac muscle

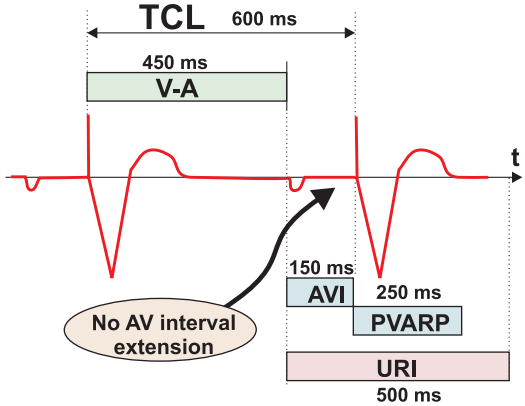
ENDLESS LOOP TACHYCARDIA AT UPPER RATE





ENDLESS LOOP TACHYCARDIA SLOWER THAN UPPER RATE



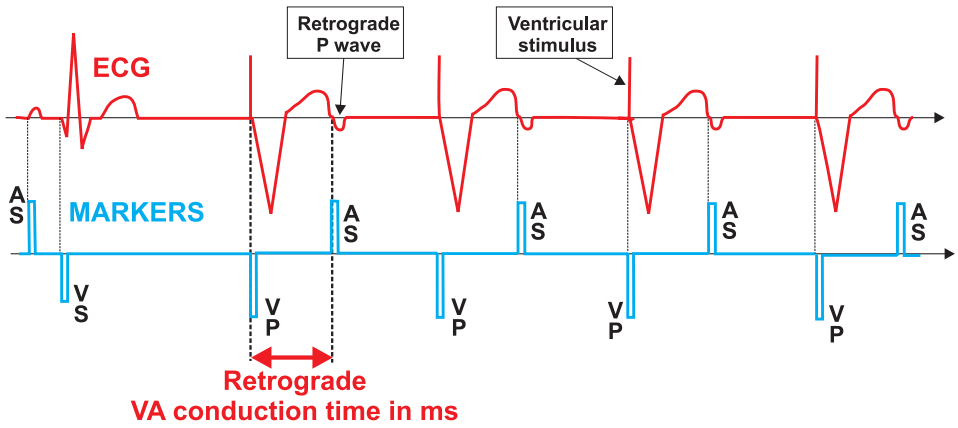


Abbreviations : AVI = atrioventricular interval ; AVE = extension of AVI ; ELT = endless loop tachycardia ; PVARP = postventricular atrial refractory period ; TARP = total atrial refractory period ; URI = upper rate interval; V-A = retrograde V-A conduction time; TCL = tachycardia cycle length

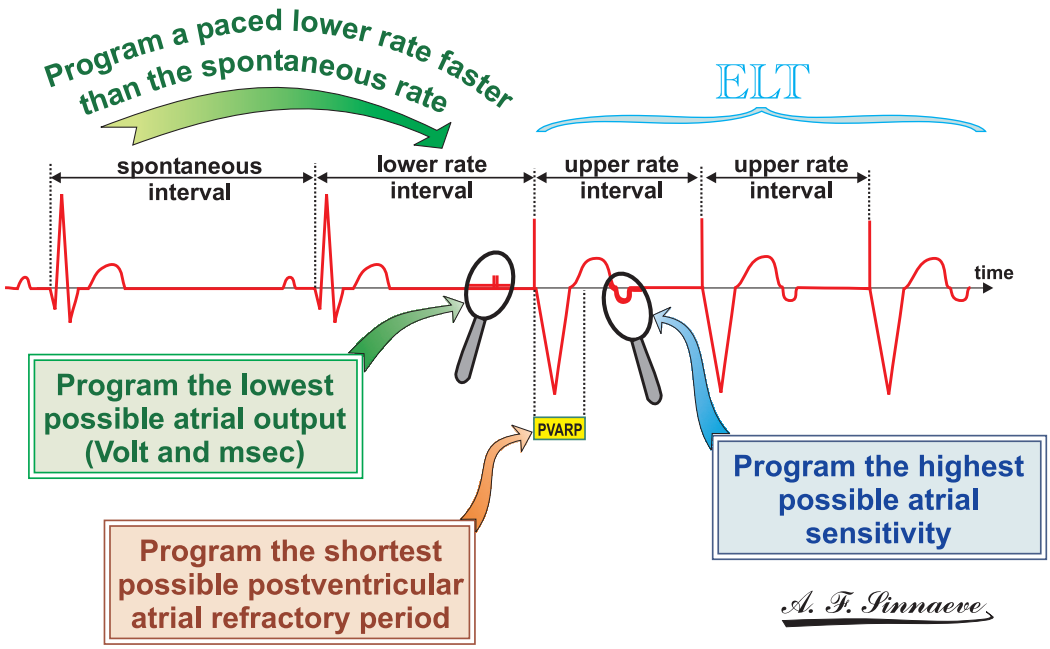
A. F. Sinnaeve

EVALUATION OF RETROGRADE VA CONDUCTION

Reprogram the pacemaker to the VVI mode at a rate faster than the spontaneous rhythm

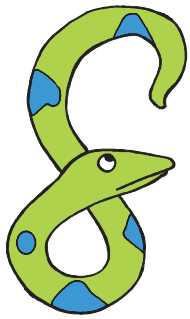


TEST FOR PROPENSITY TO ENDLESS LOOP TACHYCARDIA

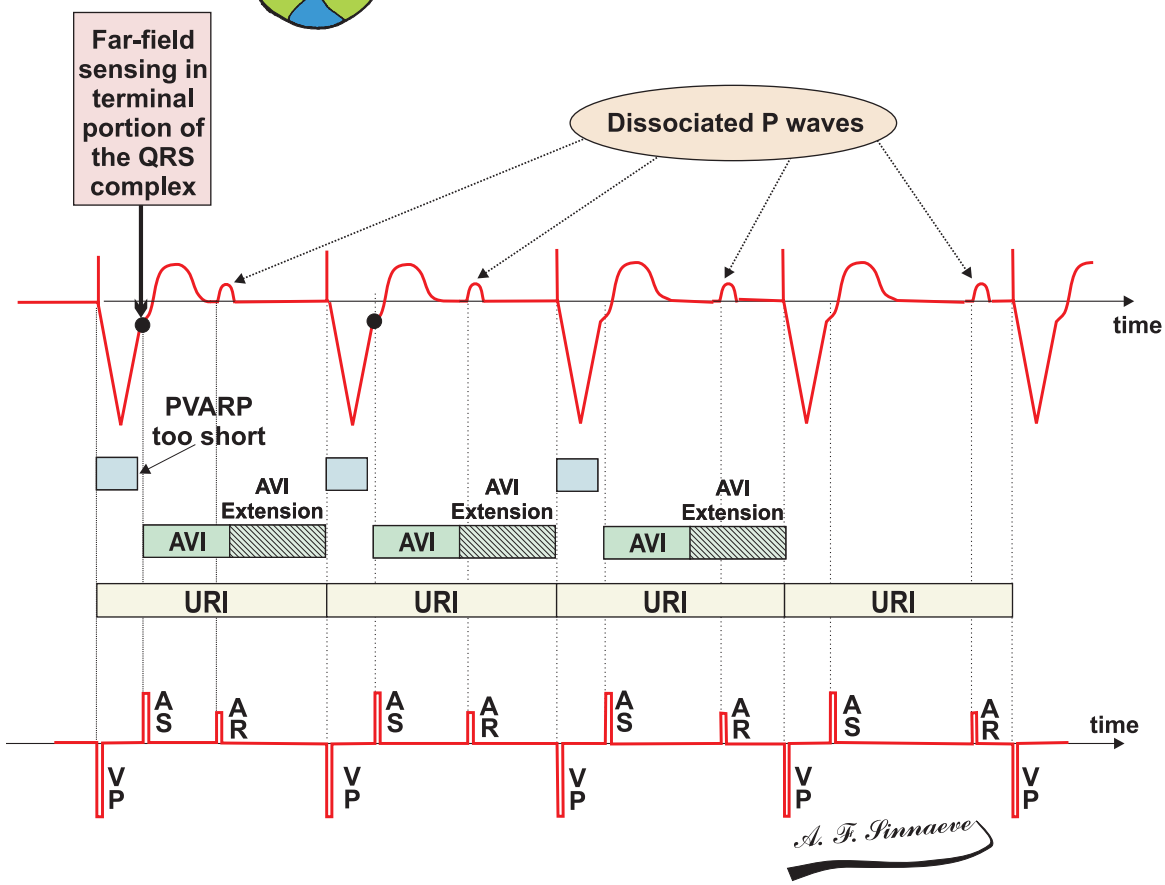


Abbreviations : AS = atrial sense ; ELT = endless loop tachycardia ; ms = millisecond ; PVARP = postventricular atrial refractory period ; VA = ventriculoatrial ; VP = ventricular pace ; VS = ventricular sense

FAR-FIELD ENDLESS LOOP TACHYCARDIA

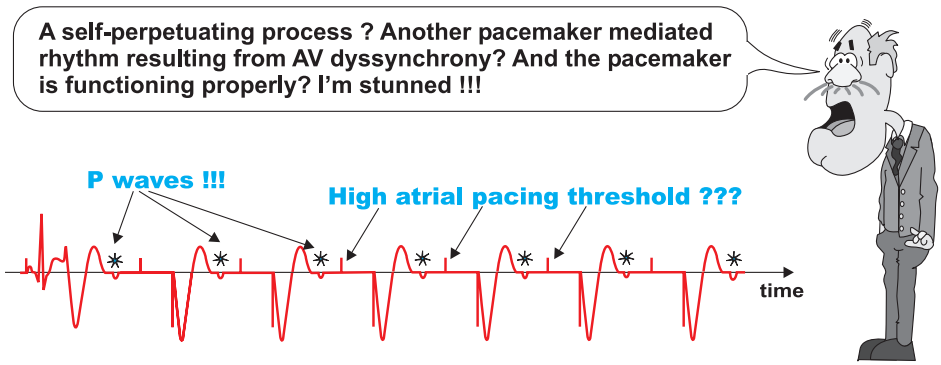


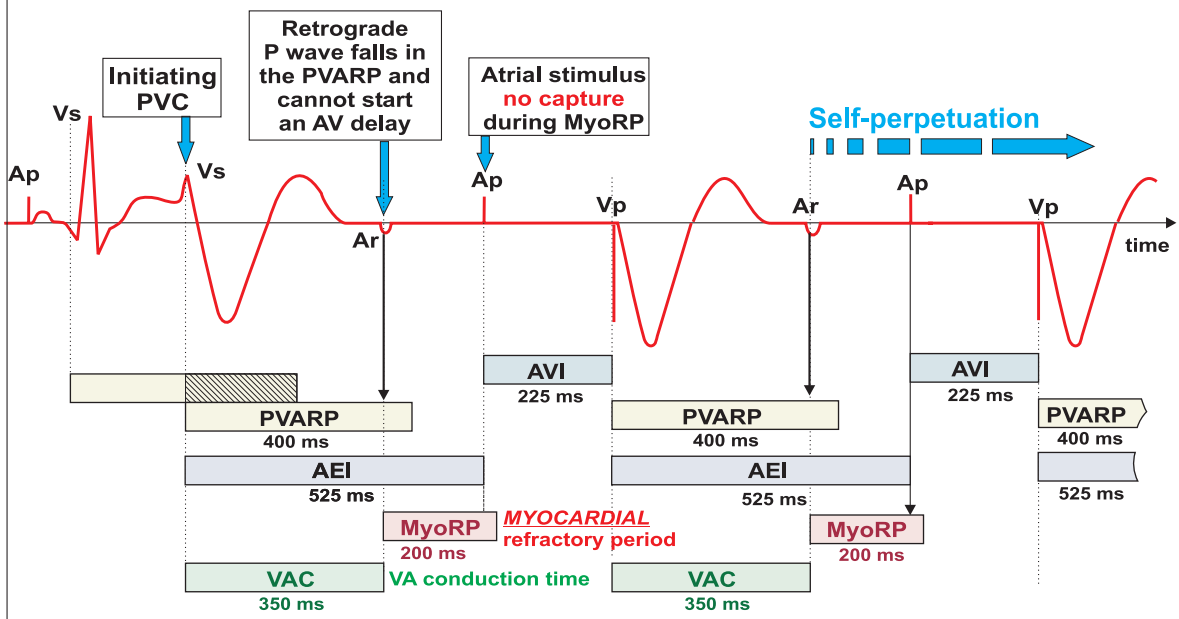
IN CAUDA VENENUM !!!



Abbreviations : AS = atrial sense ; AR =atrial sense in refractory period ; VP = ventricular pace ; AVI = atrioventricular interval ; URI = upper rate interval ; PVARP = postventricular atrial refractory period ;
In cauda venenum = (latin) the venom is in the tail !

REPETITIVE NONREENTRANT VA SYNCHRONY (RNRVAS)





PREDISPOSING FACTORS
- * Long VA conduction time
- * Long PVARP
- * Short LRI (lower rate interval)
- * Long AVI

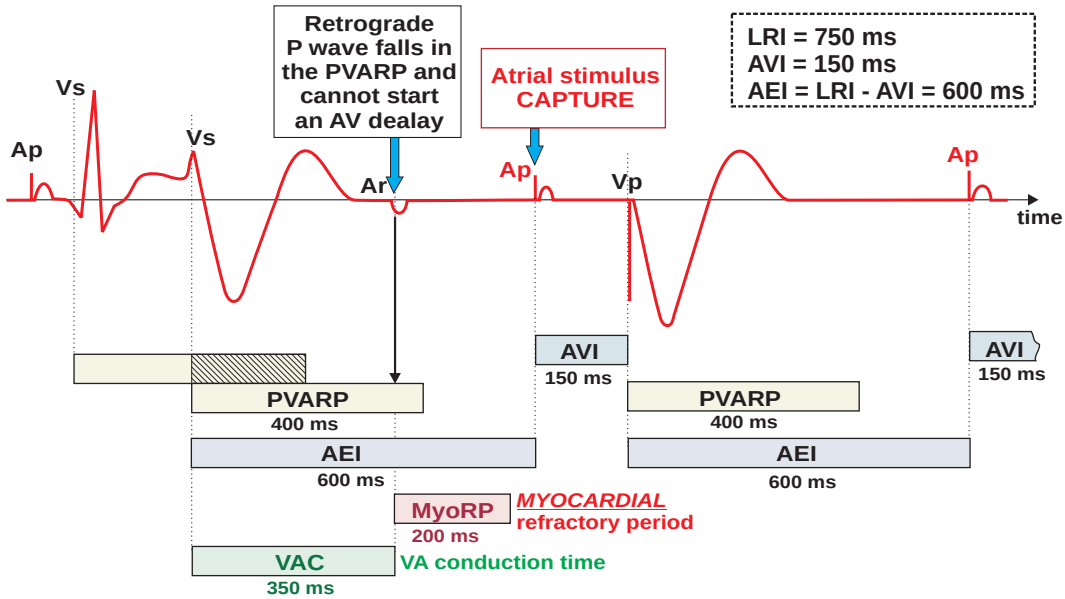
Abbreviations : Ap = atrial pace ; Ar = atrial sense during refractory period ; Vp = ventricular pace ; Vs = ventricular sense ; AVI = pacemaker AV delay ; PVARP = postventricular atrial refractory period ; PVC = ventricular premature complex ; AEI = atrial escape interval

A. F. Sinnaeve

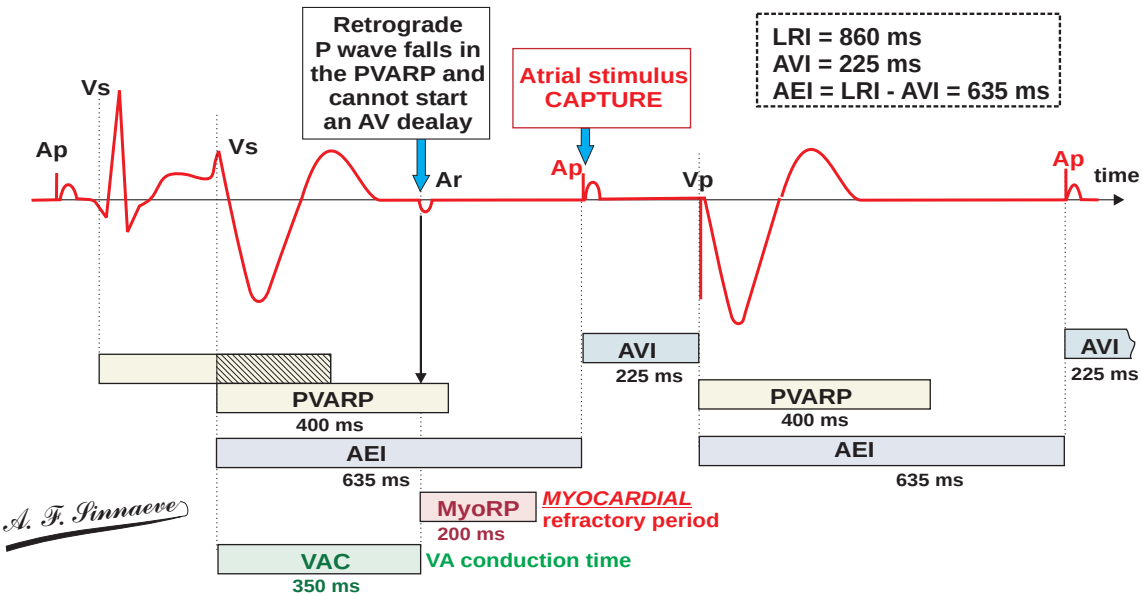
RNRVAS - PREVENTION AND TREATMENT

PROLONGATION OF THE ATRIAL ESCAPE INTERVAL TO DISPLACE THE ATRIAL STIMULUS FROM THE RETROGRADE P WAVE

CORRECTION 1 : SHORTER AVI



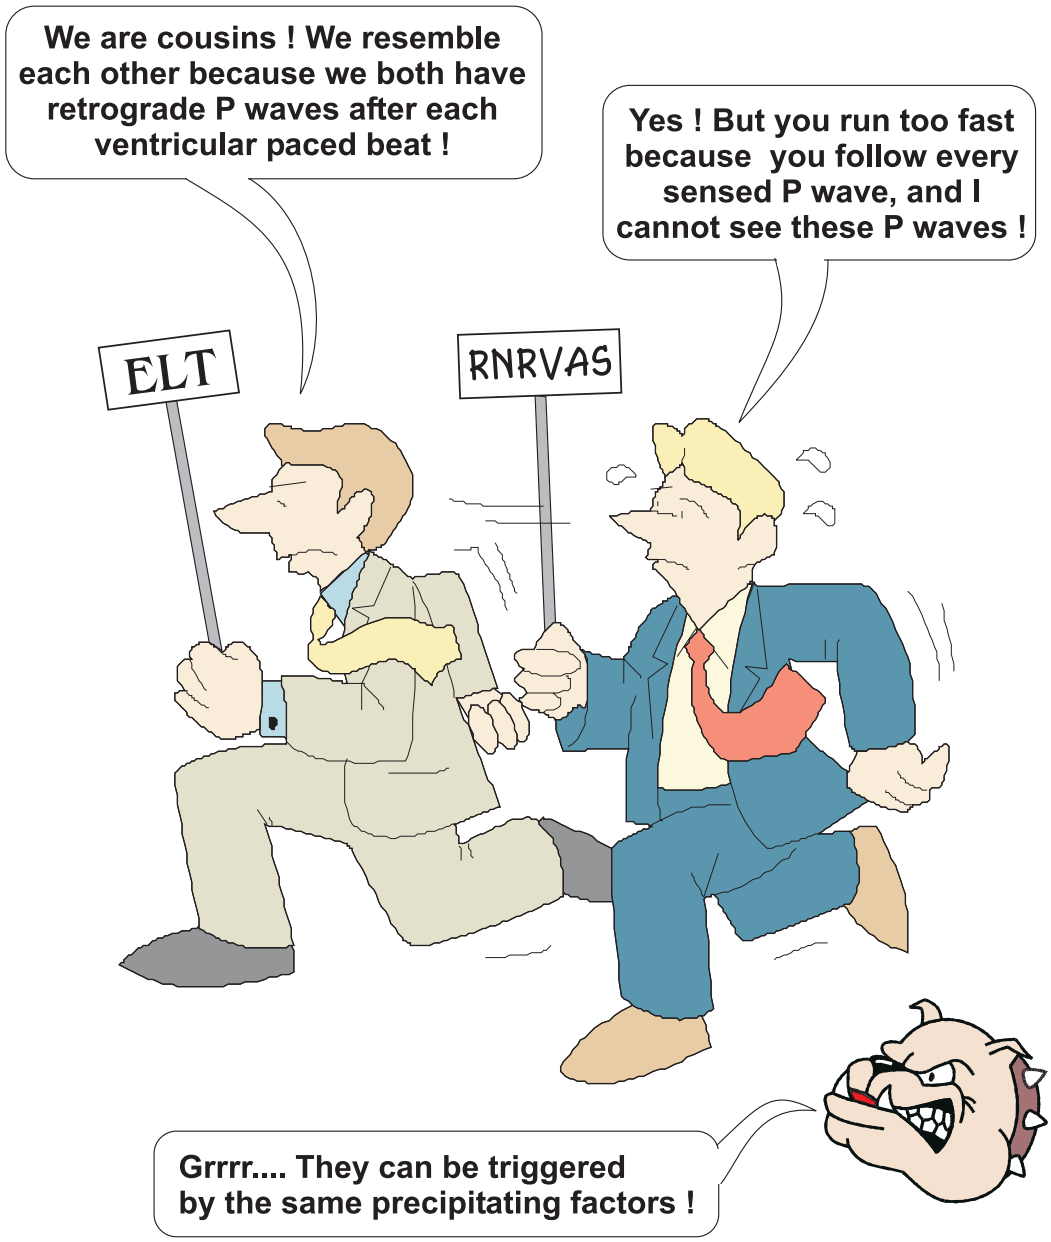
CORRECTION 2 : LONGER LRI



A. F. Sinnaeve

Abbreviations : AEI = atrial escape interval ; Ap = atrial pace ; Ar = atrial sense during refractory period ; Vp = ventricular pace ; Vs = ventricular sense ; AVI = pacemaker AV delay ; PVARP = postventricular atrial refractory period ; PVC = ventricular premature complex ; LRI = lower rate interval ; RNRVAS = repetitive nonreentrant VA synchrony

SUSTAINED PACEMAKER MEDIATED RHYTHMS RELATED TO VENTRICULOATRIAL (VA) SYNCHRONY



Abbreviations : ELT = endless loop tachycardia
RNRVAS = repetitive non-reentrant VA synchrony

ALGORITHMS FOR AUTOMATIC TERMINATION OF ENDLESS LOOP TACHYCARDIA

DETECTION OF THE TACHYCARDIA

* number of consecutive paced cycles at upper rate
* number of consecutive paced cycles above a programmed rhythm
* stability of the Vp-As (VP) interval

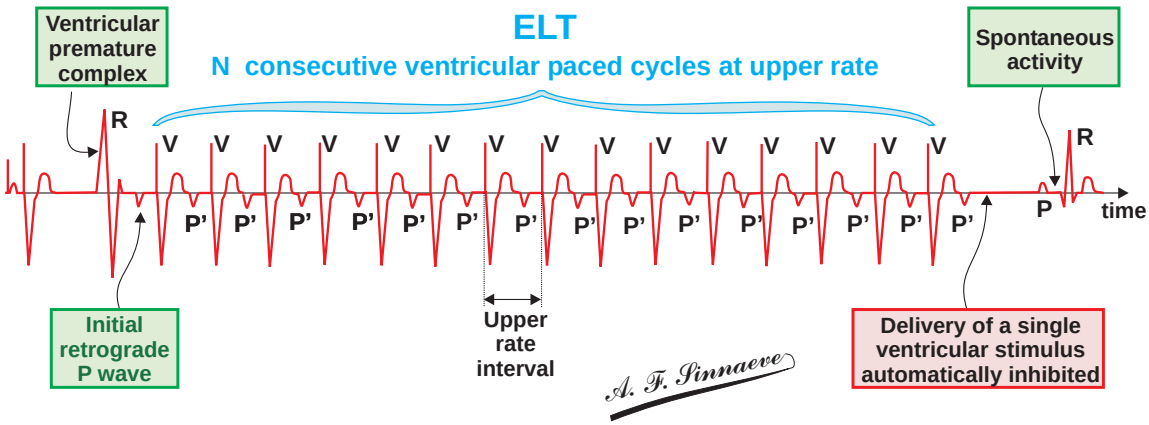
TERMINATION OF THE TACHYCARDIA by uncoupling atrial and ventricular events

* Inhibition of one (1) ventricular stimulus
* extension of one (1) PVARP to contain the following P wave

AFTER THE INTERVENTION

* spontaneous atrial activity at normal rate
* atrial pacing at an appropriate rate
* restart of detection if there is still a tachycardia

System 1 : number of ventricular paced cycles at upper rate

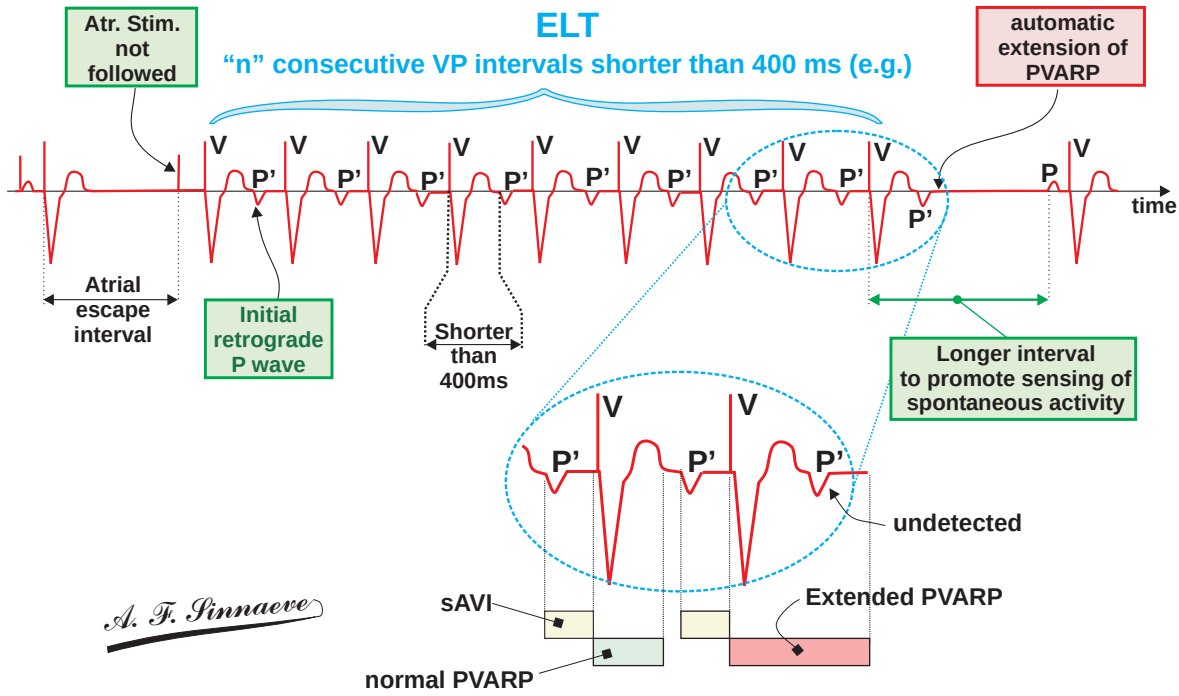


In some pacemakers, the number N of consecutive ventricular paced cycles may be programmable.

Abbreviations : ELT = endless loop tachycardia = PMT = pacemaker-mediated tachycardia ; P = anterograde P wave ; P' = retrograde P wave ; PVARP = postventricular atrial refractory period ; R = spontaneous ventricular event ; sAVI = sensed AV delay ; V = ventricular stimulus ; VP = Vp-As = interval between a ventricular stimulus and the consequent atrial event

ALGORITHMS FOR AUTOMATIC TERMINATION OF ENDLESS LOOP TACHYCARDIA

System 2 : “n” consecutive Vp-As or VP intervals shorter than a given value



A PMT (= ELT) may be present if the following criteria are fulfilled :
*** “n” consecutive VP intervals shorter than a specified duration**
*** all intervals start with a ventricular paced event**
*** all intervals end with an atrial sensed event**

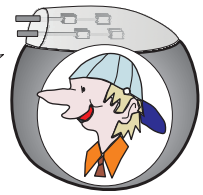
Some models have sensor corroboration before intervening i.e. they only assume a PMT if the sensor indicated interval is longer (or sensor indicated rate is slower) than a certain value to prevent misdiagnosis of sinus tachycardia for PMT

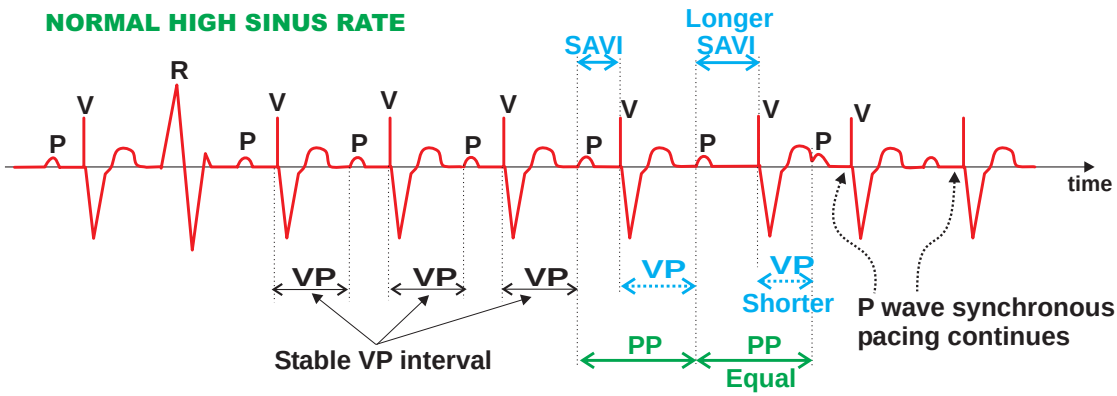
Abbreviations : ELT = endless loop tachycardia = PMT = pacemaker-mediated tachycardia ; P = anterograde P wave ; P’ = retrograde P wave ; PVARP = postventricular atrial refractory period ; R = spontaneous ventricular event ; sAVI = sensed AV delay ; V = ventricular stimulus ; VP = Vp-As = interval between a ventricular stimulus and the consequent atrial event

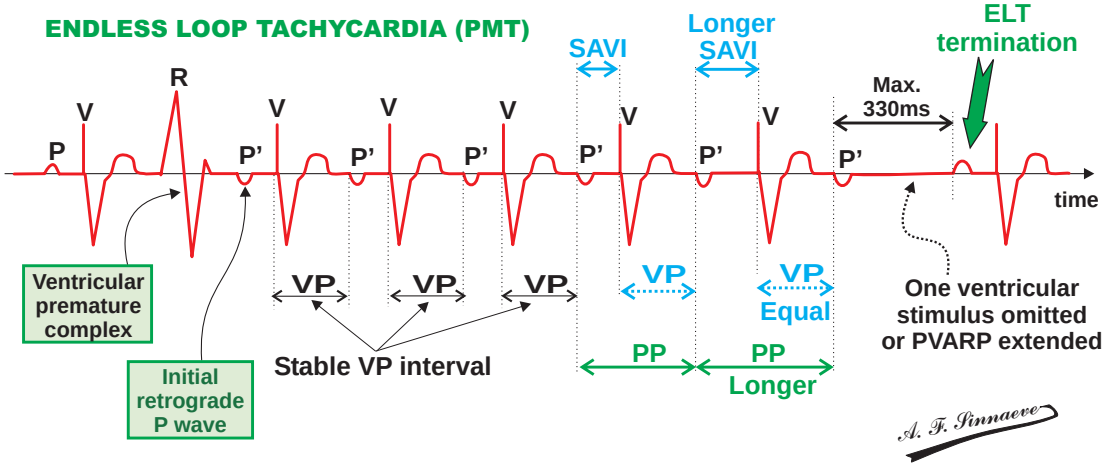
ALGORITHMS FOR AUTOMATIC TERMINATION OF ENDLESS LOOP TACHYCARDIA

System 3 : monitoring the VP interval

VP is the interval from the ventricular stimulus to the point of sensing atrial depolarization. I know that a stable VP interval might indicate a possible ELT or PMT. My microprocessor is instructed to monitor such stable intervals and to change the sAVI upon detection of it ! If the VP interval remains constant, the P in the VP interval is a retrograde P wave (P').







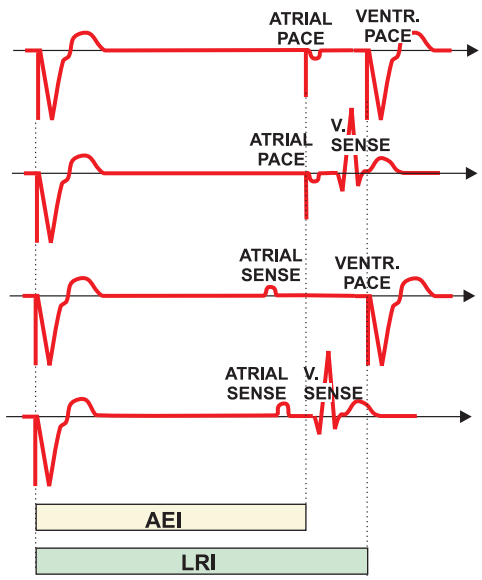
Abbreviations : ELT = endless loop tachycardia = PMT = pacemaker-mediated tachycardia ; P = anterograde P wave ; P' = retrograde P wave ; R = spontaneous ventricular event ; sAVI = sensed AV delay ; V = ventricular stimulus ; VP = interval between a ventricular stimulus and the consequent atrial event

DDD

DVI ? VDD ? DOO ? DDI ?

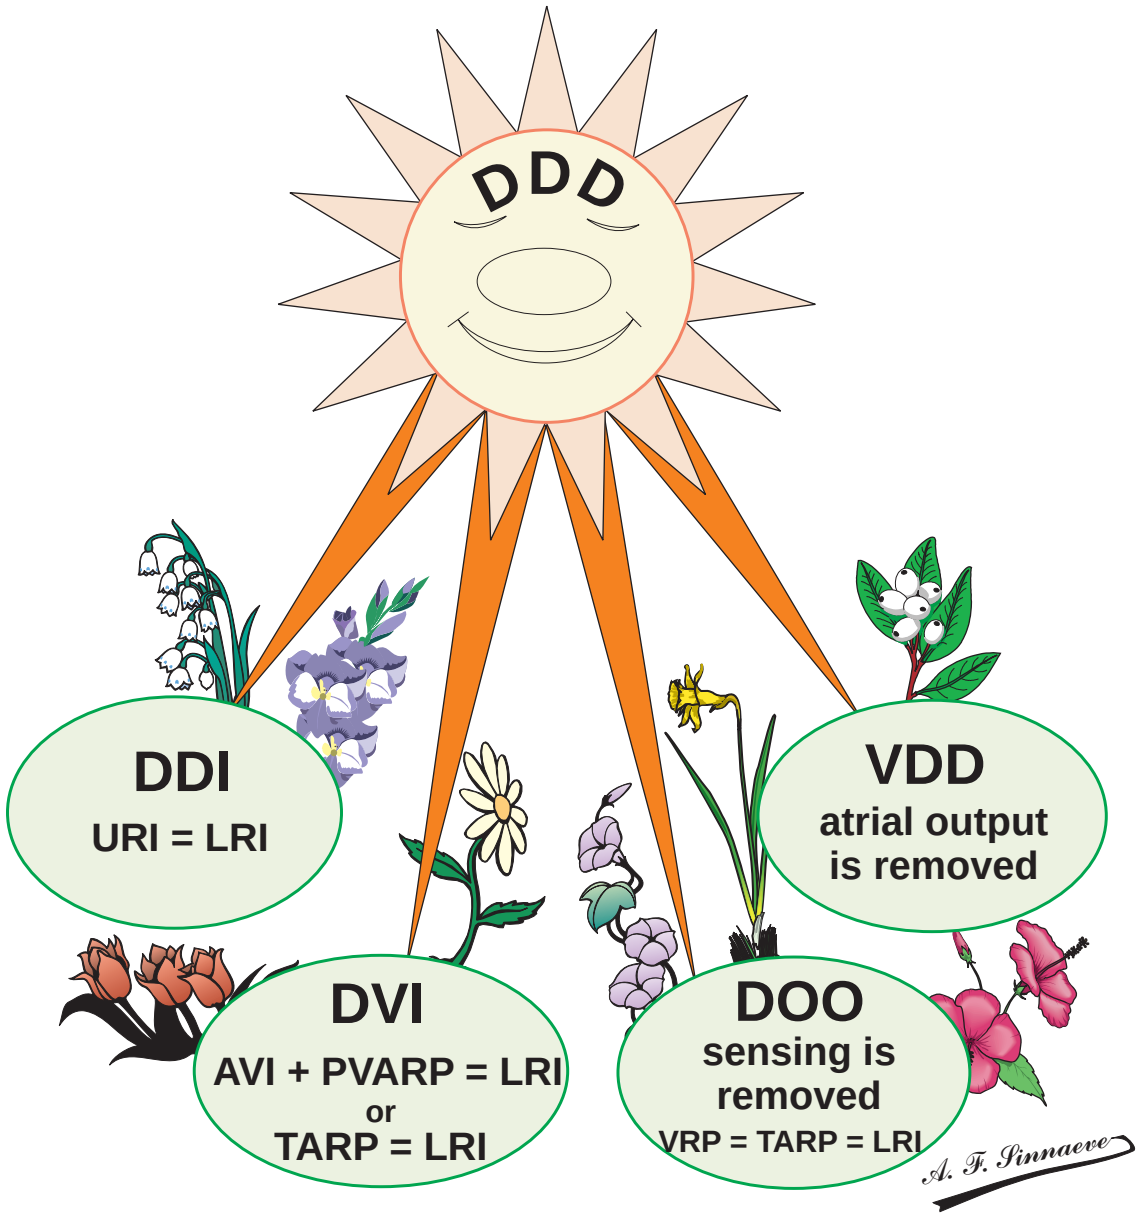
ALL DUAL CHAMBER PACEMAKERS FUNCTION IN THE DDD MODE

* The garden of dual chamber pacemakers
* The DVI mode
* The DDI mode
* The VDD mode
* Two types of VDD timing cycles
* Single lead VDD pacing
* Selection of pacing mode - 1
* Selection of pacing mode - 2

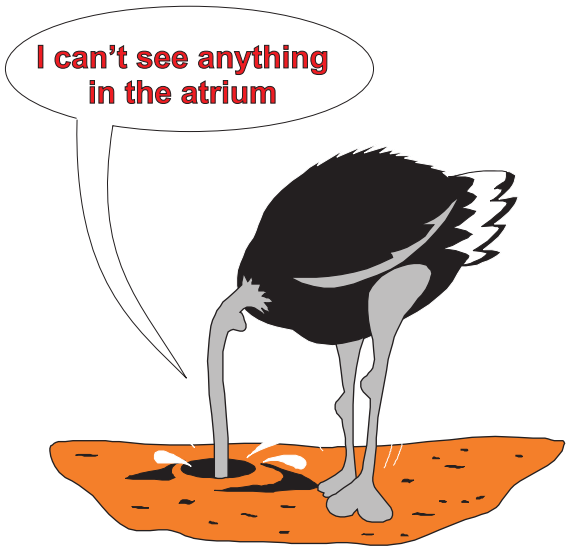


A. F. Sinnaeve

DDD GOVERNS THE GARDEN OF DUAL CHAMBER PACING

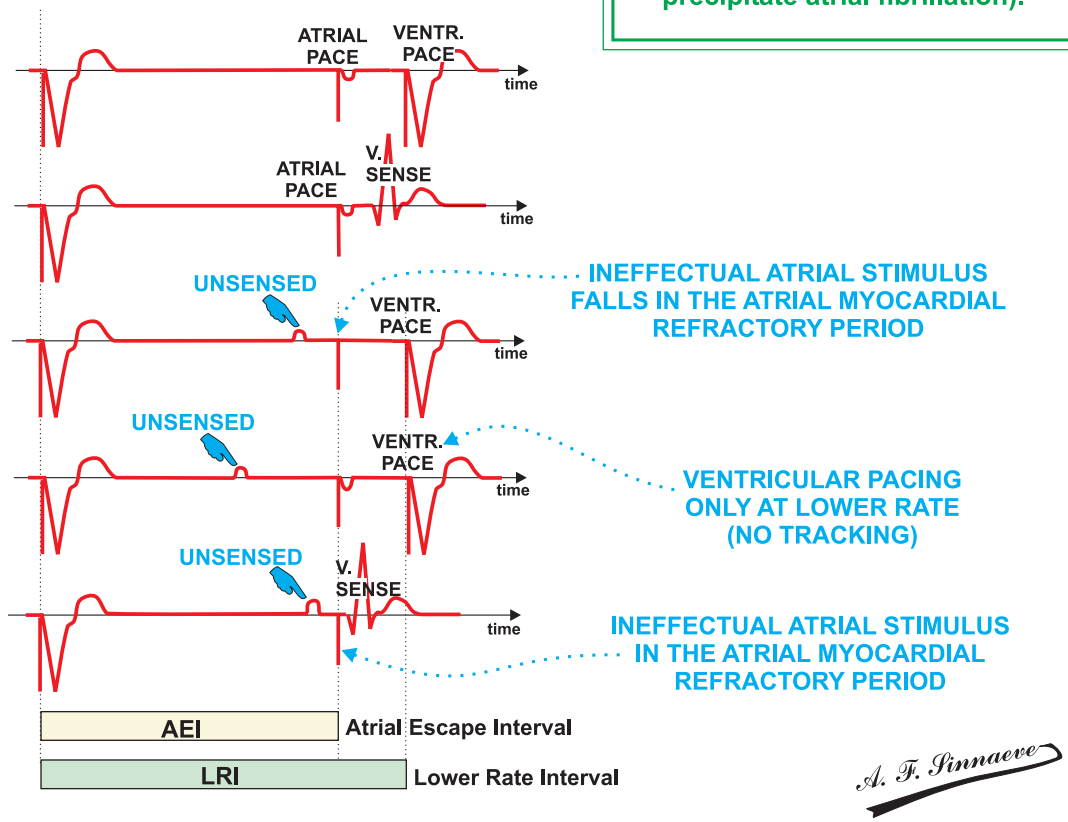


Abbreviations : URI = upper rate interval; LRI = lower rate interval; AVI = atrioventricular interval or AV delay; PVARP = postventricular atrial refractory period; TARP = total atrial refractory period; VRP = ventricular refractory period



DUAL CHAMBER PACING in DVI MODE

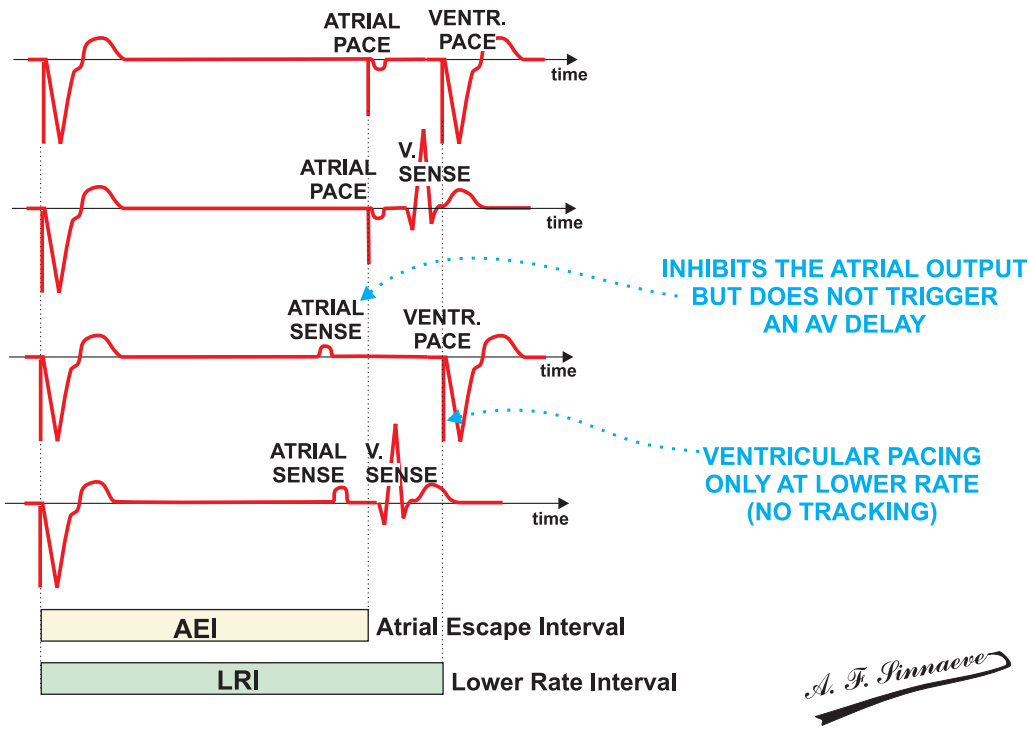
Pacing occurs in both the atrium and ventricle (D) but there is only sensing in the ventricle (V). The mode of response is inhibition (I). No sensing of the atrial electrogram and lack of tracking results in asynchronous atrial pacing (competitive atrial pacing may precipitate atrial fibrillation).



A. F. Sinnaeve

DUAL CHAMBER PACING in DDI MODE

Pacing and sensing occur in both the atrium and ventricle (DD) and the mode of response is inhibited (I).
Sensed atrial activity inhibits the atrial output impulse, but does not trigger a ventricular output impulse. In other words an atrial sensed event cannot produce a physiologic AV delay equal or shorter to the AV delay initiated by an atrial paced event .



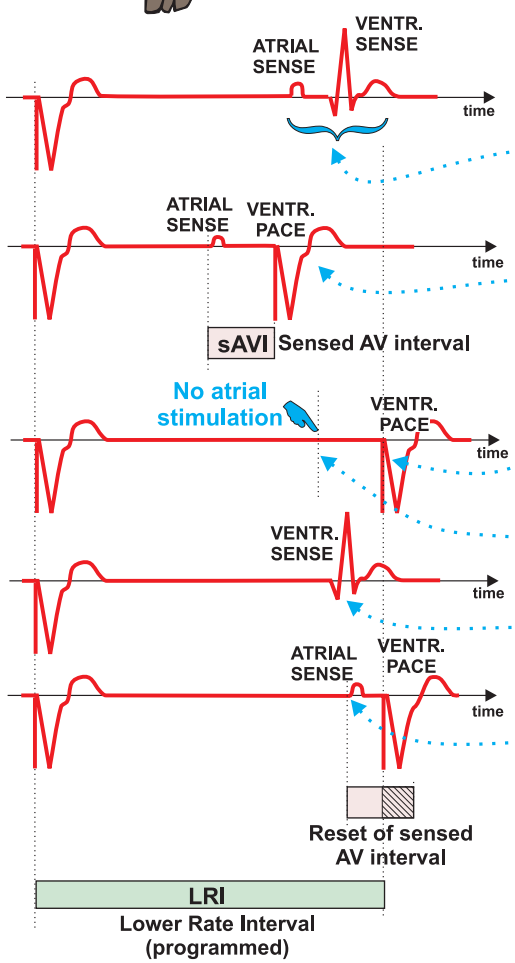
A. F. Sinnaeve

DUAL CHAMBER PACING in VDD MODE

In the VDD mode there is no atrial stimulus and therefore no AV crosstalk. There are no crosstalk timing cycles : postatrial ventricular blanking period and ventricular safety pacing function.

But, this is not for me... This is for young people and they can have fast upper rates!!!

Pacing occurs in the ventricle only (V) but there is sensing in both the atrium and ventricle (D). The mode of response is inhibition and triggering (D).
A sensed atrial event triggers (T) a ventricular stimulus after completion of the AVI. A sensed ventricular event inhibits the ventricular output (I). Hence the response is T + I = D.



Atrial sensing. Conducted QRS occurs before completion of the AV delay and therefore inhibits the ventricular stimulus

Atrial tracking : atrial sensing followed by ventricular pacing after the programmed AV delay

VVI pacing at the lower rate during sinus bradycardia slower than the programmed pacemaker lower rate

As there is no atrial stimulation, there is no need for an atrial escape interval

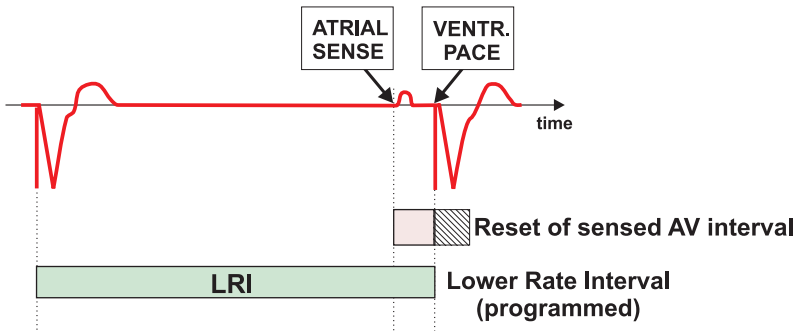
Resets the lower rate interval

The P wave is sensed but not tracked, i.e. it does not trigger a ventricular stimulus after the programmed AV delay. The P wave is not tracked because it falls in the implied AV delay which terminates with the emission of a ventricular stimulus at the completion of the lower rate interval.

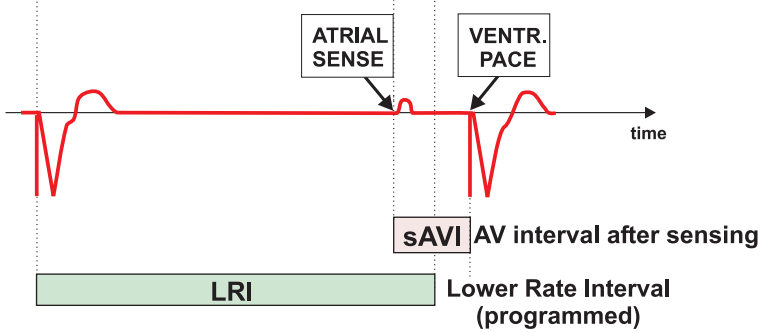
A. F. Sinnaeve

2 TYPES OF VDD TIMING CYCLES

TYPE 1 : The lower rate interval dominates

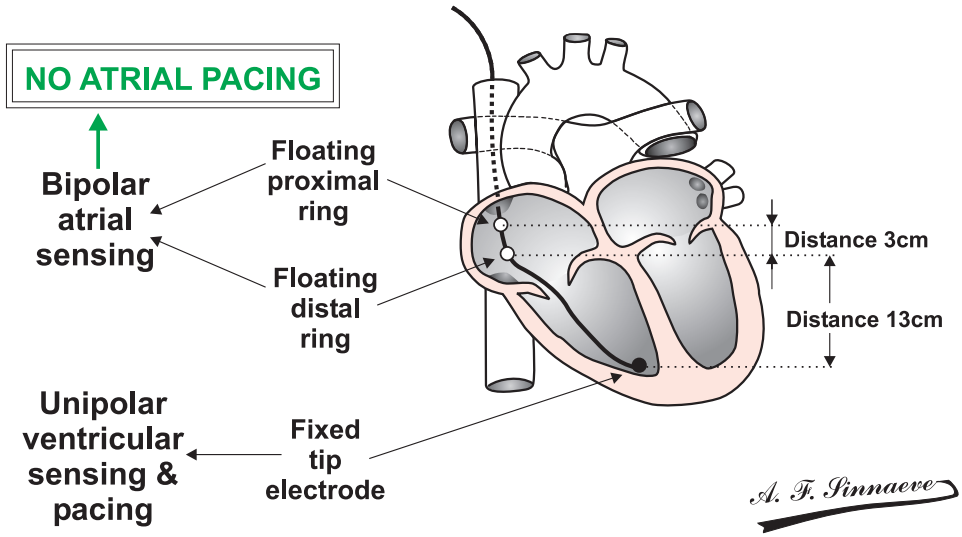


TYPE 2 : The AV delay (sAVI) dominates



A. F. Sinnaeve

SINGLE LEAD VDD PACING



Atrial signals from floating (non-contact) electrodes tend to be small and therefore high atrial sensitivity is required for sensing

This system should not be used in patients with sick sinus syndrome (sinus bradycardia) or atrial chronotropic incompetence (abnormal response of atrial rate on exercise)

WHICH PACING MODE SHOULD BE CHOSEN? A DECISION TREE

START

Check carefully the ATRIAL RHYTHM

Any persistent or predominant atrial tachyarrhythmias present ?

Yes

No

Is the response to exercise chronotropic adequate ?

Yes

No

VVI ventricular demand pacing

VVIR rate-adaptive ventr. demand pacing

Is the present or anticipated AV conduction normal?

Yes

No

Is the response to exercise chronotropic adequate ?

Yes

No

AAI atrial demand pacing

AAIR rate-adaptive atrial demand pacing

Is the response to exercise chronotropic adequate ?

Yes

No

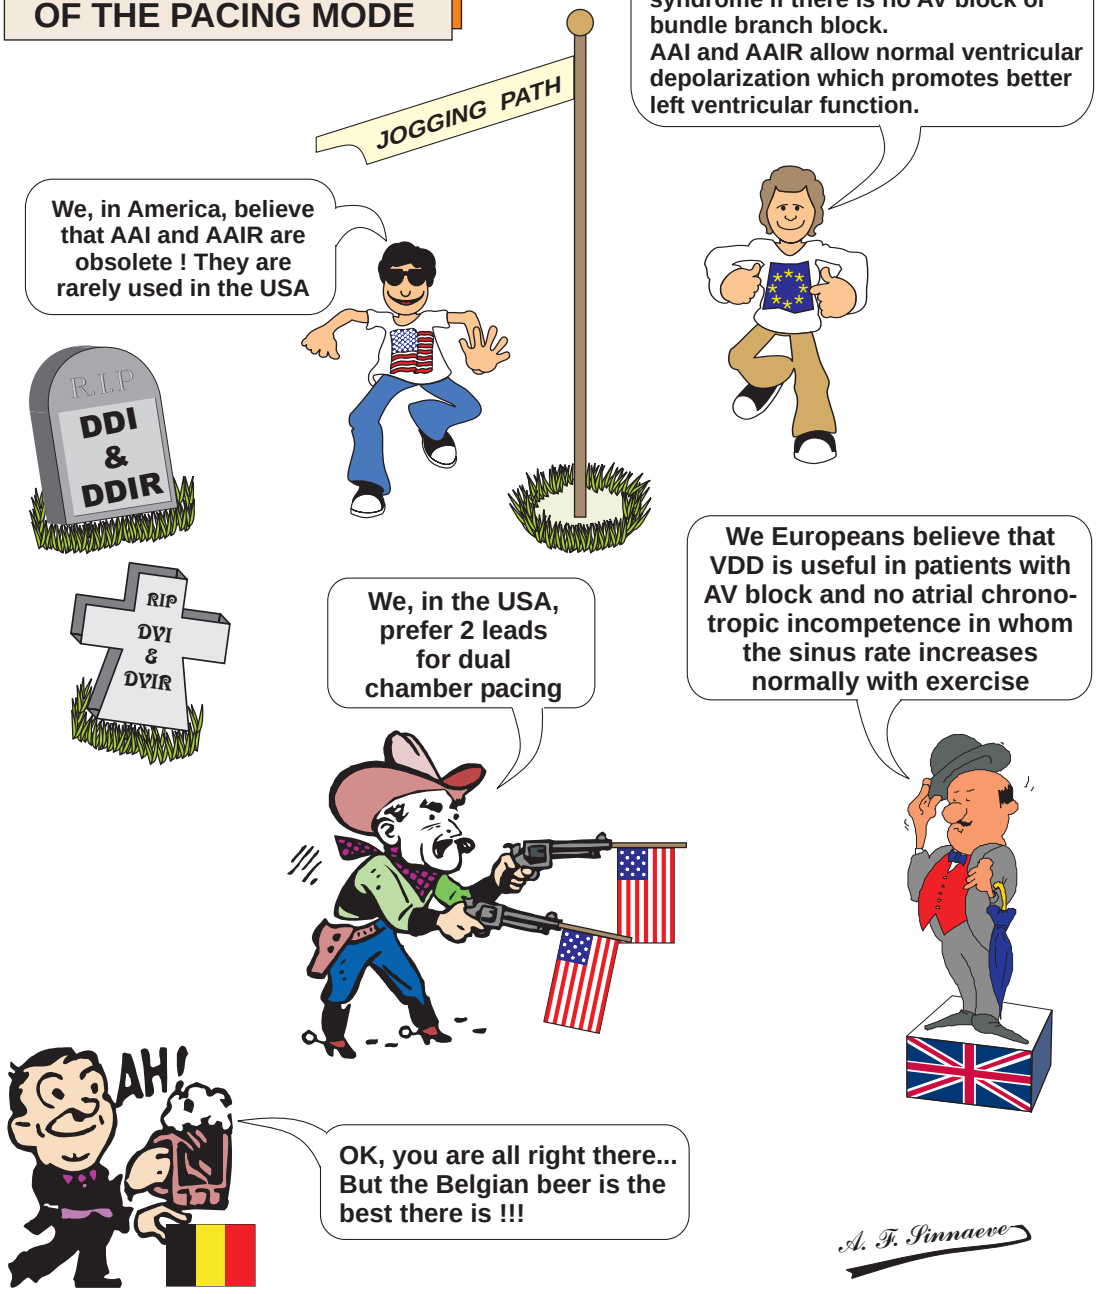
DDD dual chamber AV synchron. pacing

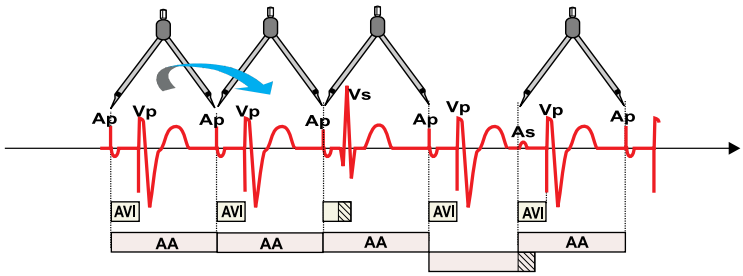
DDDR rate-adaptive dual chamber pacing

A. F. Simaeve

Note : VVIR, DDDR and AAIR are equal to VVI, DDD and AAI modes respectively with additional rate-adaptive function provided by an artificial sensor for rate increase on activity.

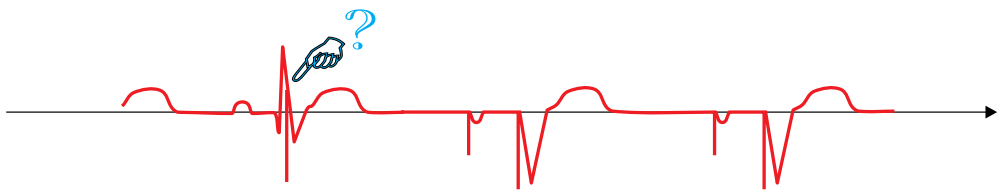
CONTROVERSIES IN THE SELECTION OF THE PACING MODE





TYPES OF LOWER RATE TIMING

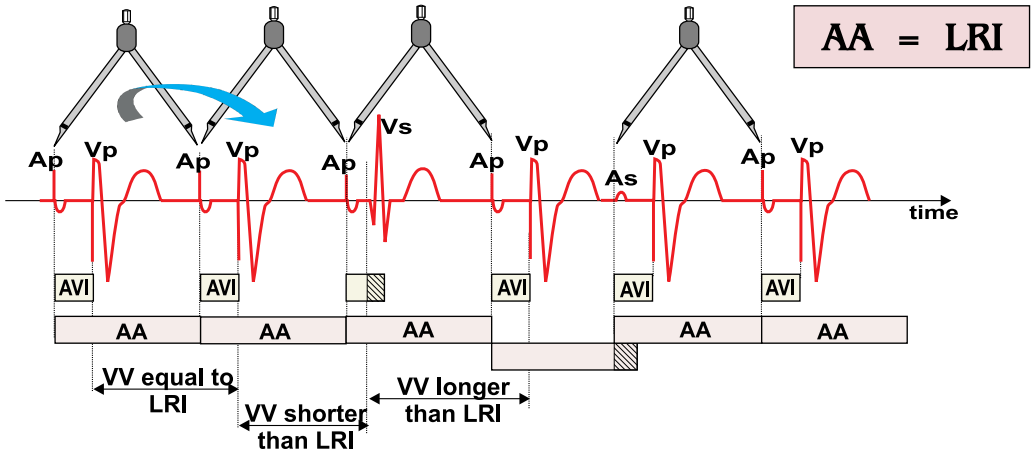
* Atrial-based lower rate timing - part 1.
* Atrial-based lower rate timing - part 2.
* Atrial-based lower rate timing - part 3 (AV delay).
* Faster atrial pacing rate with ventricular-based lower rate timing.
* What is the pacing mode during inhibition ?
* Spike in QRS complex.



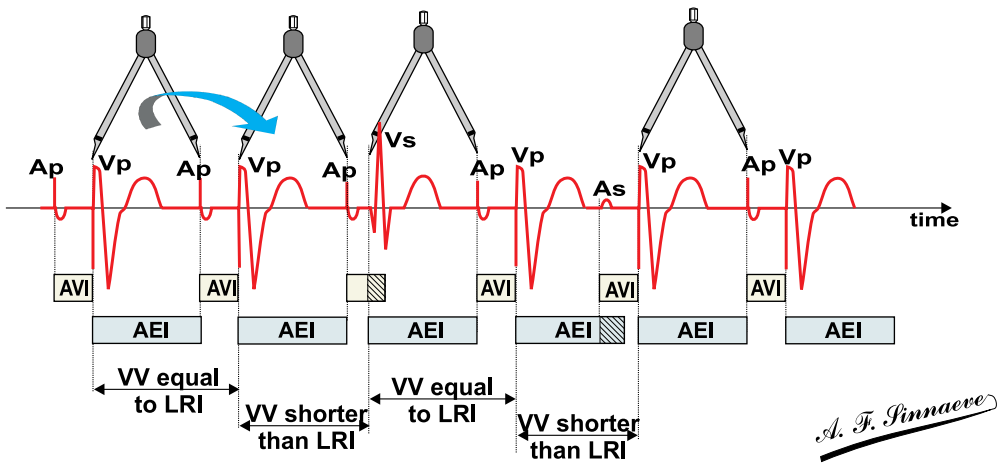
A. F. Sinnaeve

ATRIAL-BASED LOWER RATE TIMING - PART 1

With atrial-based lower rate timing, the AA interval (Ap-Ap or As-Ap) is constant and equal to the programmed LRI. The atrial escape interval (Vp-Ap or Vs-Ap) varies to maintain a constant AA interval as shown in this example where Vs-Ap > Vp-Ap .

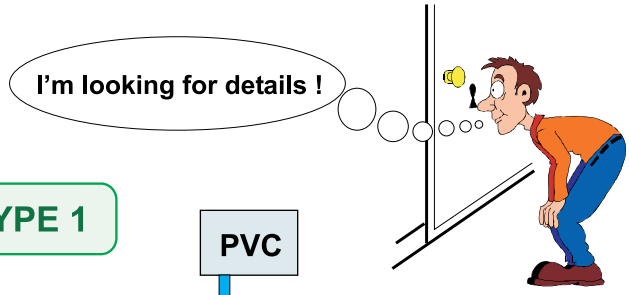


With ventricular-based lower rate timing the AEI or atrial escape interval (Vp-Ap or Vs-Ap) is constant

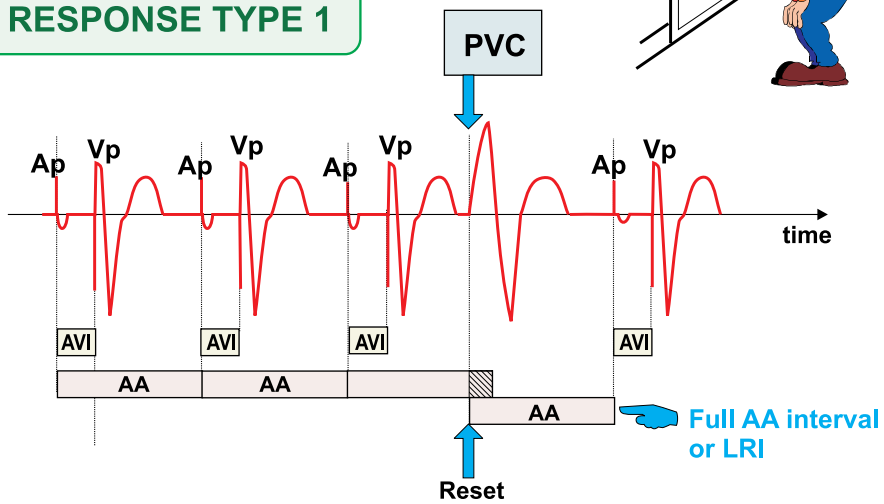


Abbreviations : Ap = atrial pace ; As = atrial sense ; AEI = atrial escape interval ; AVI = AV delay ; AA = programmed atrial lower rate interval = Ap-Ap or As-Ap ; LRI = lower rate interval ; VV = interval between two consecutive ventricular events

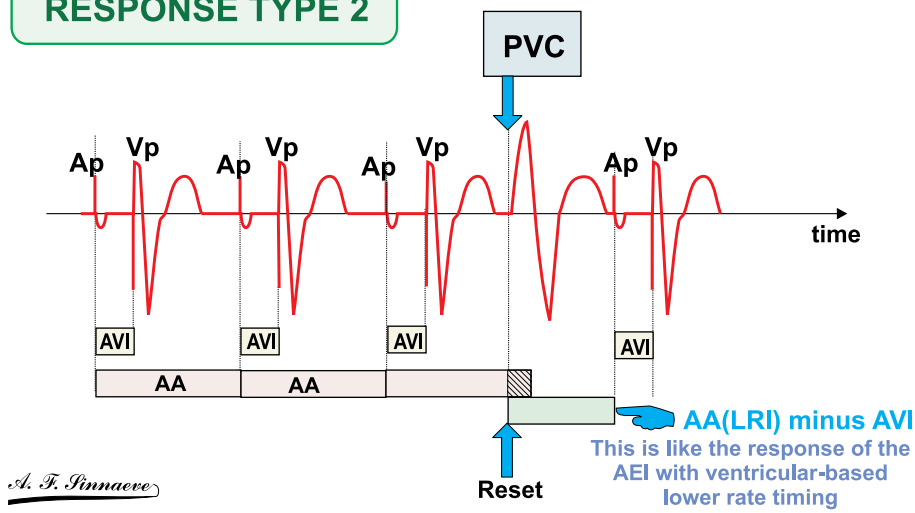
ATRIAL-BASED LOWER RATE TIMING - PART 2
Response after a premature ventricular complex (PVC)



RESPONSE TYPE 1



RESPONSE TYPE 2



A. F. Simmaeve

Abbreviations : Ap = atrial pace ; As = atrial sense ; AEI = atrial escape interval ; AVI = AV delay ;
AA = programmed atria-based lower rate interval = Ap-Ap or As-Ap interval ;
LRI = lower rate interval ; PVC = premature ventricular complex

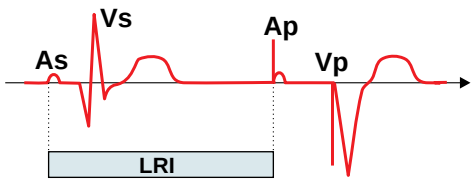
ATRIAL-BASED LOWER RATE TIMING - PART 3

This is a difficult subject !!!
Which circumstances involving the AV delay will activate atrial-based lower rate timing ??

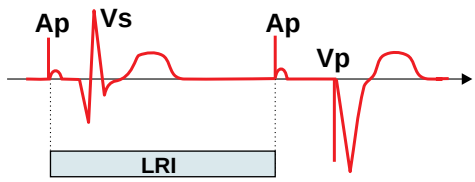
We know that circumstances causing an *AV delay longer than the programmed value* are always associated with ventricular-based lower rate timing

When the *AV delay is shorter than the programmed value* of Ap-Vp any number of the following combinations of AV delay can initiate atrial-based lower rate timing

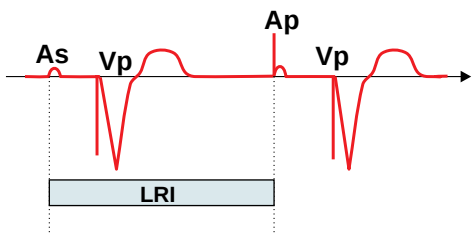
As-Vs
normal conduction



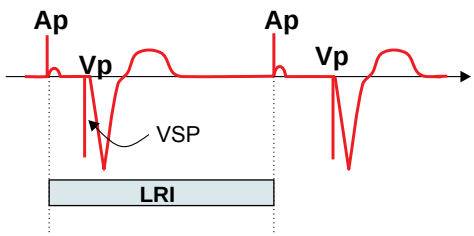
Ap-Vs
normal conduction



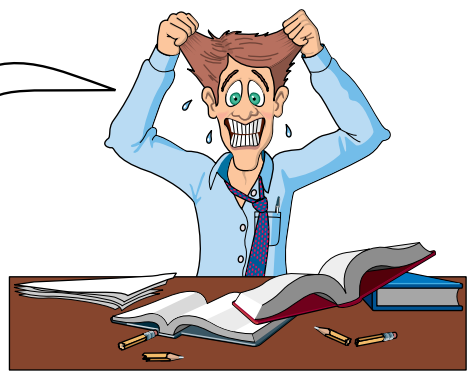
As-Vp < Ap-Vp
programmed shorter than Ap-Vp



Abbreviated Ap-Vp
(ventricular safety pacing due to crosstalk)



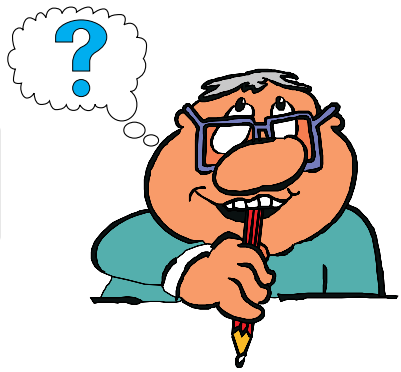
Any one of the combinations of AV delay (As-Vp, As-Vs, Ap-Vs, abbreviated Ap-Vp) can initiate atrial-based lower rate timing. Without knowledge of the type of lower rate timing according to circumstances, one cannot interpret the ECG !!!!

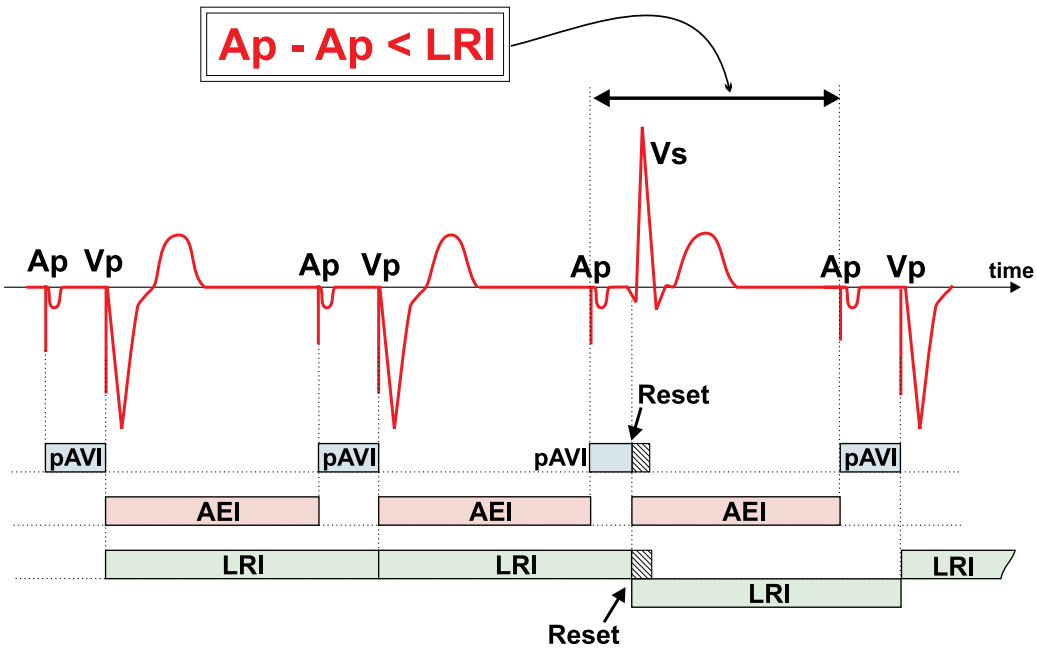


Abbreviations : AVI = AV delay ; AEI = atrial escape interval ; AVE = extension of AVI ; LRI = lower rate interval ; Ap = atrial pacing ; As = atrial sensing ; Vp = ventricular pacing ; Vs = ventricular sensing ; VSP = ventricular safety pacing

A. F. Sinnaeve

THE ATRIAL PACING RATE MAY BE FASTER THAN THE PROGRAMMED LOWER RATE





With ventricular-based lower rate timing, the atrial escape interval (AEI) and the lower rate interval (LRI) start from a sensed or paced ventricular event. The hallmark of ventricular-based lower rate timing is constancy of the AEI

Abbreviations : Ap = atrial pace ; Vp = ventricular pace ; Vs = ventricular sense ;
pAVI = AV delay after pacing ; AEI = atrial escape interval ;
LRI = lower rate interval

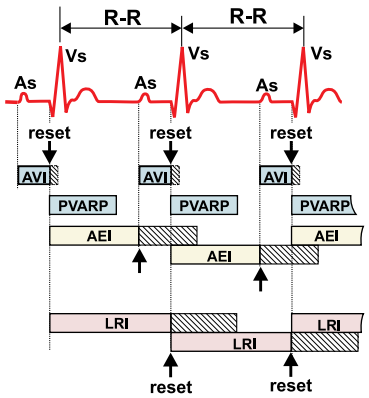
A. F. Sinnaeve

YOU MAY HAVE A QUESTION ABOUT THE PACING MODE IF THE R-R INTERVAL IS SHORTER THAN THE ATRIAL ESCAPE INTERVAL

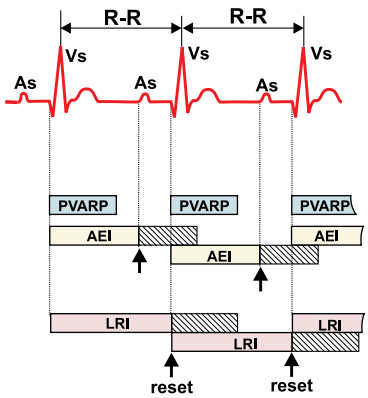
At relatively fast spontaneous rates and normal AV conduction, nobody can tell whether the mode is DDD or DDI or DVI by only looking at the ECG !!!

DDD, DDI or DVI modes with R-R or Vs-Vs interval < AEI

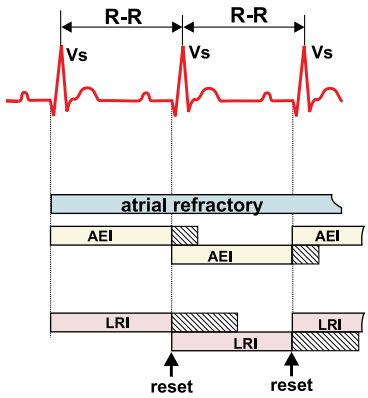
DDD MODE



DDI MODE



DVI MODE



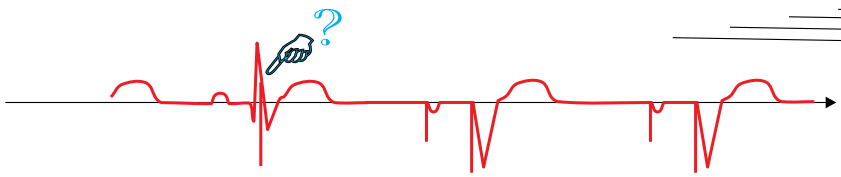
The same ECG may also represent the VDD mode if As-Vs < programmed As-Vp and the spontaneous atrial rate is faster than the programmed lower rate

A. F. Sinnaeve

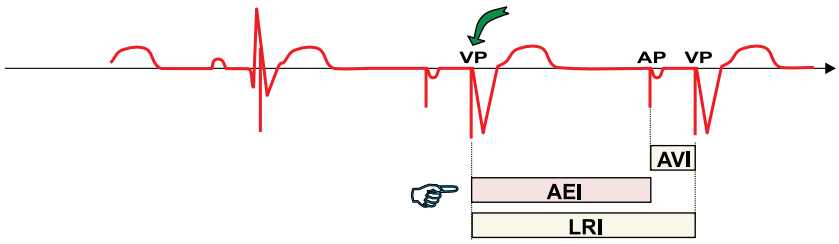
Abbreviations : As = atrial sense ; Vs = ventricular sense ; AVI = AV delay ; AEI = atrial escape interval ; LRI = lower rate interval ; PVARP = postventricular atrial refractory period

It took some time and a lot of exercise to become an expert in marching backwards, but at the end it isn't difficult at all.....

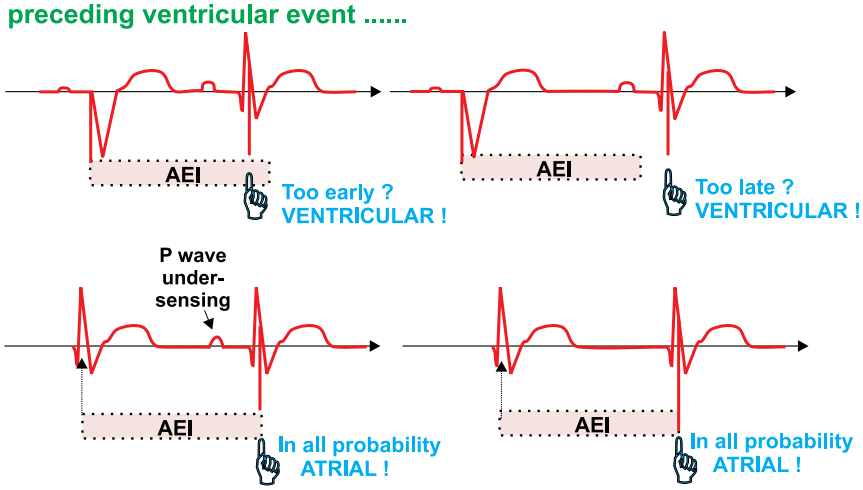
A SPIKE WITHIN A QRS COMPLEX ! IS IT AN ATRIAL OR A VENTRICULAR STIMULUS ?



① **Establish the duration of the AEI, starting with any VP**
(alternatively the duration of AEI can be determined from the onset of a sensed QRS complex to the succeeding atrial stimulus)



② **Measure the interval from the stimulus in question back to the preceding ventricular event .....**



This rule is only valid for DDD pacemakers with ventricular-based lower rate timing

A. F. Sinnaeve

Abbreviations : Ap = atrial pace; Vp = ventricular pace; AEI = atrial escape interval; AVI = AV delay; LRI = lower rate interval

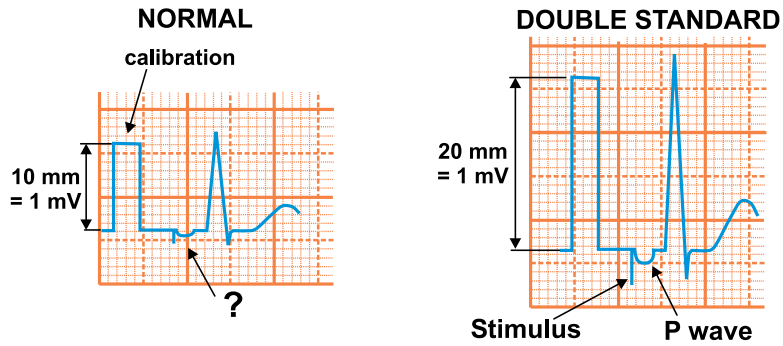
HOW TO TEST FOR ATRIAL CAPTURE - PART1

ONE

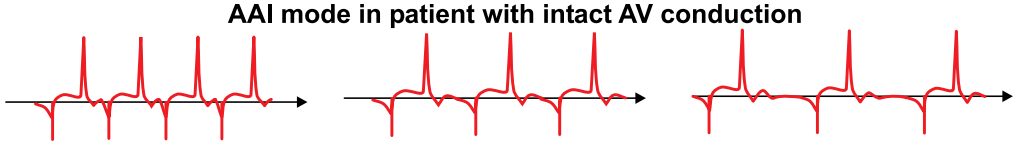
Take a 12-lead ECG recorded at double standardization to bring out paced P waves and/or tiny bipolar stimuli



TWO

Reprogram to the AAI or AOO mode (at several pacing rates)

AAI mode in patient with intact AV conduction



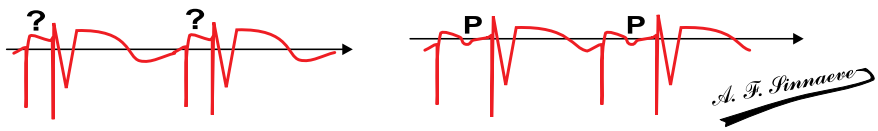
Atrial capture is present when the rate of the conducted QRS complexes (ventricular rate) always remains equal to the changing atrial pacing rates used during testing

AAI mode in patient with complete AV block and idioventricular rhythm

This maneuver can only be performed if there is an underlying ventricular rhythm during AAI pacing. A spontaneous ventricular rhythm is often present when the pacing rate in the VVI mode is slowly decreased to allow the emergence of a slow spontaneous idioventricular rhythm. If this rate is satisfactory, testing is done in the AAI mode.

THREE

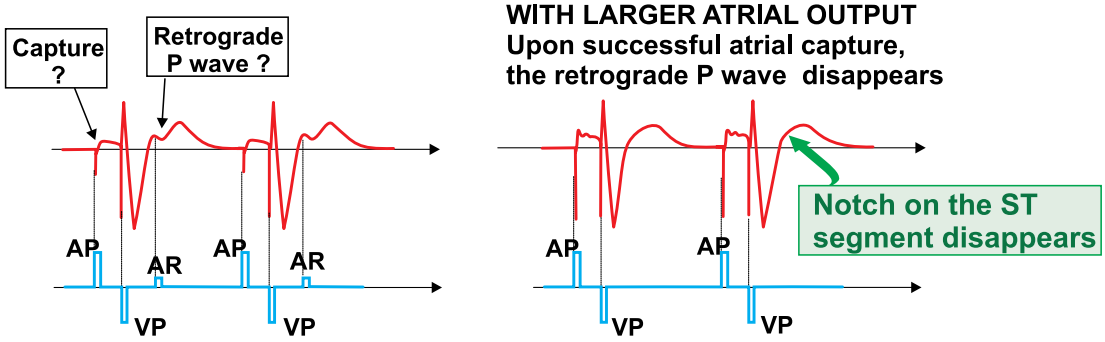
Unmask P waves by programming a long AV delay (250-300 ms) e.g. with latency or considerable delay in interatrial conduction



HOW TO TEST FOR ATRIAL CAPTURE - PART2

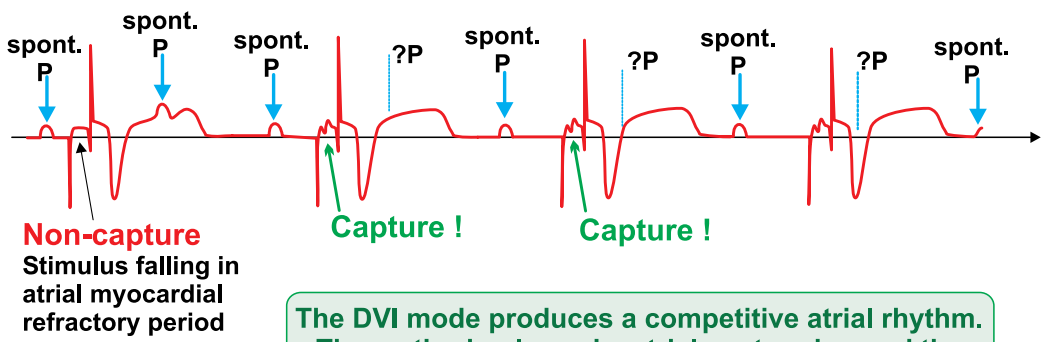
FOUR

Retrograde VA conduction suggests lack of capture by the preceding atrial stimulus. Verify retrograde conduction by event markers and eventually increase the atrial output to capture the atrium



FIVE

Program the DVI mode for patients with relatively fast sinus rhythm



The DVI mode produces a competitive atrial rhythm. The method only seeks atrial capture beyond the atrial myocardial refractory period

A. F. Sinnaeve

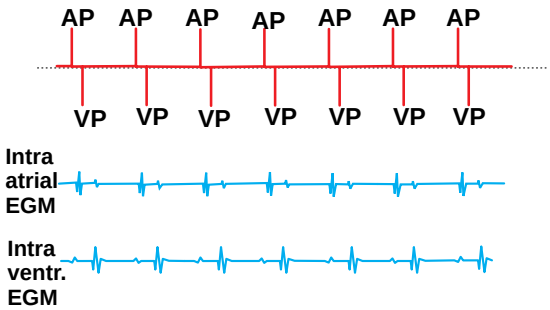
Abbreviations : AP = paced atrial event ; AR = atrial sensing in atrial refractory period ; VP = ventricular paced event ; VA = ventriculoatrial (from ventricle to atrium)

HOW TO TEST FOR ATRIAL CAPTURE - PART 3

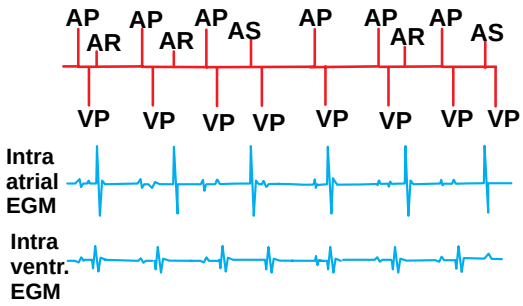
SIX

Using only the programmer, program the DDD mode and increase the atrial pacing rate above the spontaneous rate, then increase or decrease the atrial output and look at the markers

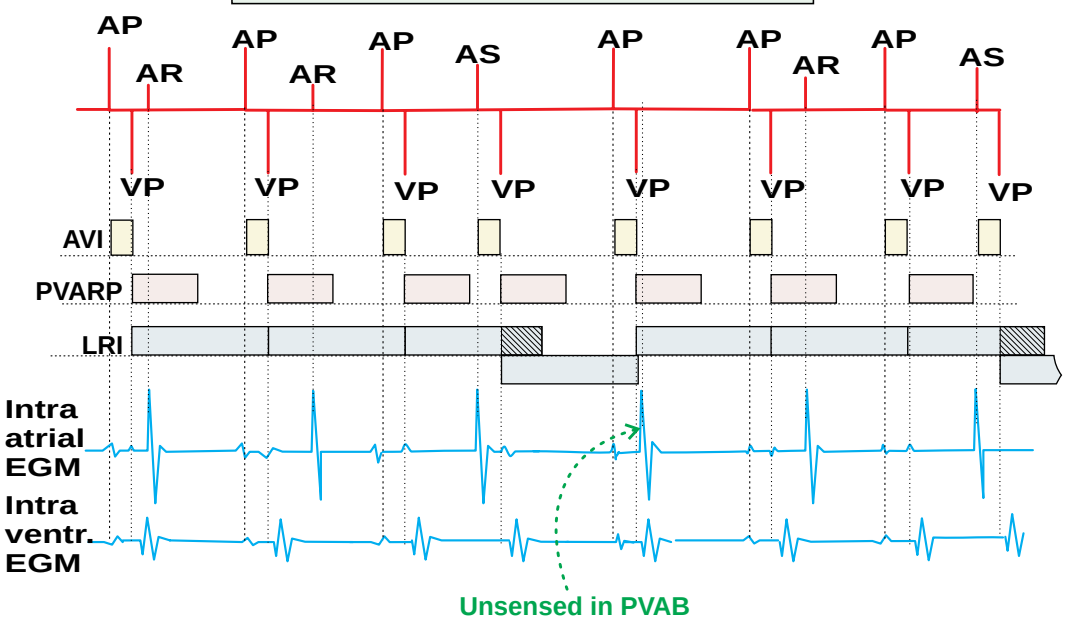
Atrial stimulus 1 V / 0.4 ms
CAPTURE !!!



Atrial stimulus O.5 V / 0.4 ms
NO CAPTURE !!!



CLARIFICATION OF THE MARKERS



Abbreviations : AVI = AV delay ; PVARP = postventricular atrial refractory period ; LRI = lower rate interval ; AP = atrial pacing ; AS = atrial sensing ; AR = atrial sensing during refractory period ; VP = ventricular pacing ; EGM = electrogram ; PVAB = postventricular atrial blanking period

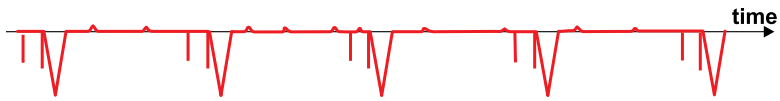
A. F. Pinnaeve

PITFALLS IN THE EVALUATION OF ATRIAL CAPTURE

1. **High threshold situation**
   Suspect hyperkalemia if the QRS is unduly wide. Hyperkalemia causes loss of atrial capture before ventricular capture.

2. **Isoelectric P waves : look at the 12 lead ECG at double standardization.**

3. **Atrial fibrillation**

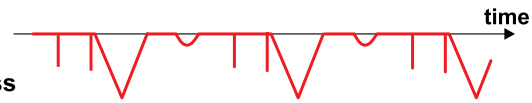


WARNING

The presence of underlying atrial fibrillation is often missed and the patient is denied anticoagulant therapy. The diagnosis is easily made on the ECG by programming the pacemaker to the VVI mode at a slow rate. Look at the telemetered atrial electrogram.

4. **Latency or delayed interatrial conduction.**
   The P wave moves towards and into the QRS. Program the maximum AV delay to bring out the P wave for diagnosis

5. **Repetitive nonreentrant VA synchrony.**
   The atrial output is supra-threshold and loss of atrial capture occurs because the atrial stimulus falls in the atrial myocardial refractory period of the preceding retrograde P wave



6. **Invisible unsensed atrial premature complex that precede the atrial stimulus which then falls in the atrial myocardial refractory period.**

THINK

The telemetered atrial electrogram helps in the diagnosis. However successful atrial capture cannot be determined from the atrial electrogram.

A. F. Sinnaeve

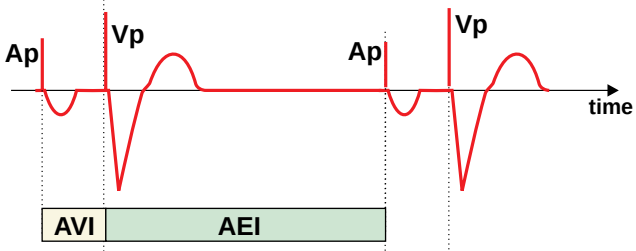
DISLODGMENT OF THE ATRIAL LEAD INTO THE RIGHT VENTRICLE

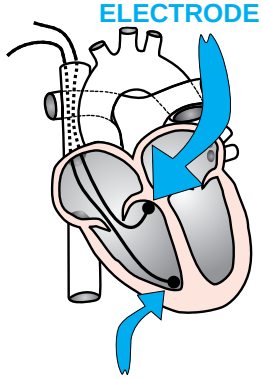
Forewarned is forearmed !!!

PART 1

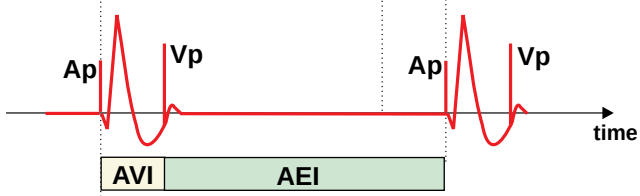
POSSIBLE PATTERNS ON ECG - LEAD II

1 **REFERENCE. Normal AV sequential pacing with programmed AVI and AEI**

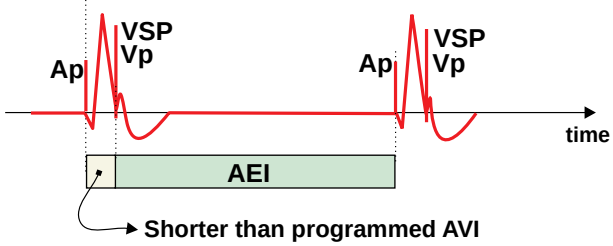




2 **When neither the atrial stimulus nor the paced QRS complex (generated by the atrial channel) is seen by the undisplaced ventricular electrode. Ap paces the RV**



3 **Crosstalk : if the atrial stimulus or the paced QRS complex generated by the displaced atrial electrode is sensed by the undisplaced ventricular electrode, ventricular safety pacing is activated whereupon the Ap-Vp interval shortens**



A. F. Sinnaeve

Abbreviations : Ap = atrial paced event; Vp = ventricular paced event;
AVI = programmed AV delay; AEI = atrial escape interval; VSP = ventricular safety pacing

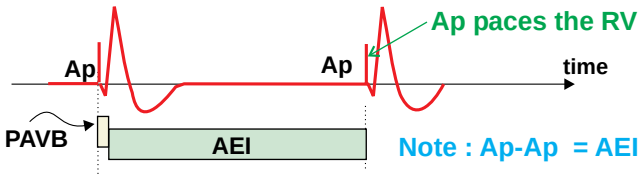
DISLODGMENT OF THE ATRIAL LEAD INTO THE RIGHT VENTRICLE

Forewarned, yes....
But still very tricky!!!

PART 2

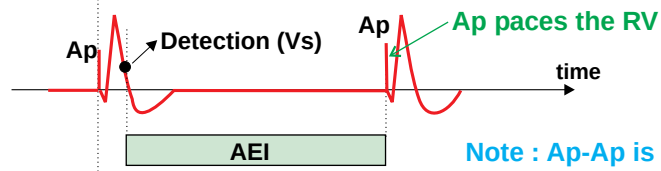
POSSIBLE PATTERNS ON ECG - LEAD II

4 **Crosstalk : if the stimulus from the displaced atrial electrode is sensed by the undisplaced ventricular electrode and the pacemaker has no VSP**



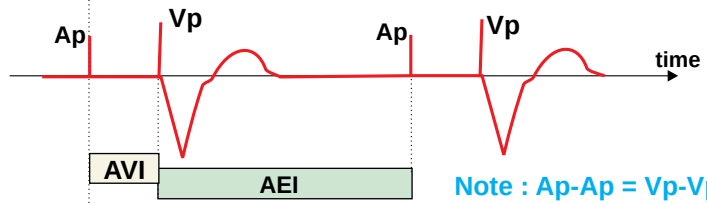
Note : Ap-Ap = AEI + PAVB = shorter than LRI

5 **The correctly positioned ventricular electrode senses a signal of the paced QRS complex induced by the dislodged atrial electrode.**
The pacemaker has no VSP or the detection (Vs) occurs after the VSP interval.



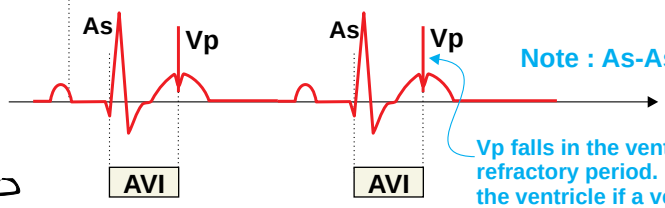
Note : Ap-Ap is still shorter than LRI

6 **Lack of capture of the displaced atrial lead (however programming the maximal atrial output may cause ventricular pacing by the atrial electrode)**



Note : Ap-Ap = Vp-Vp = AVI + AEI = LRI

7 **The atrial electrode senses the spontaneous QRS complex and delivers a ventricular stimulus after an AV delay**



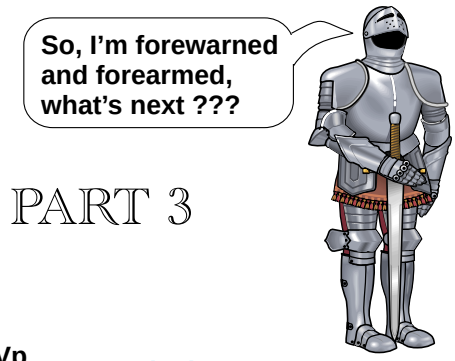
Note : As-As shorter than LRI

Vp falls in the ventricular myocardial refractory period. It may however capture the ventricle if a very long AVI is programmed

A. F. Sinnaeve

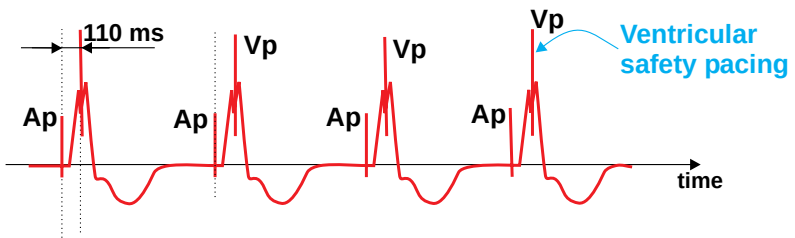
Abbreviations : Ap = atrial paced event; AEI = atrial escape interval; AVI = atrioventricular interval or AV delay; PAVB = postatrial ventricular blanking; Vp = ventricular paced event; Vs = ventricular sensed event; VSP = ventricular safety pacing; LRI = lower rate interval

DISLODGMENT OF THE ATRIAL LEAD INTO THE RIGHT VENTRICLE

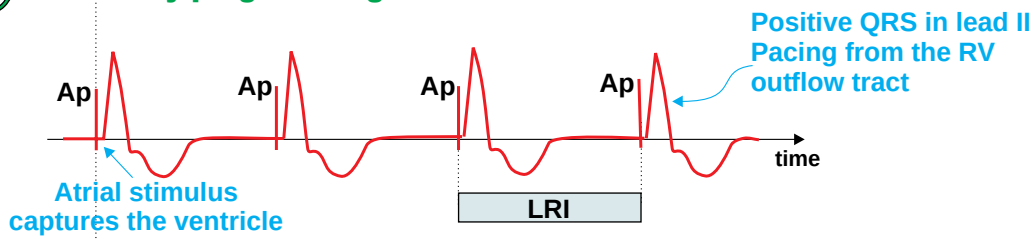


PART 3

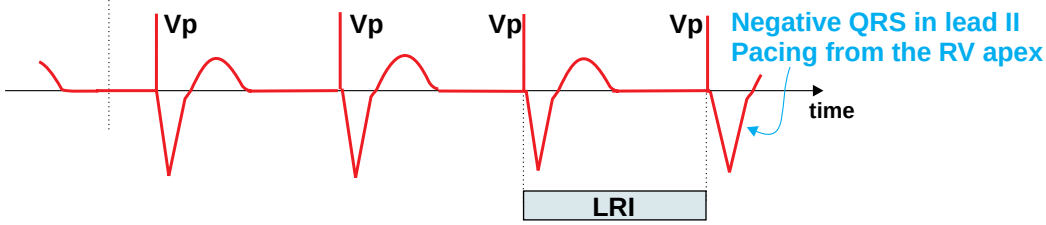
Representative ECG



① Confirm by programming to AAI mode



② and by programming to the VVI mode

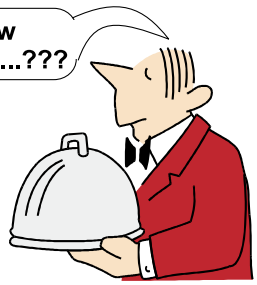


TAKE A CHEST X RAY FOR A DEFINITIVE CONFIRMATION

Abbreviations : Ap = atrial paced event; Vp = ventricular paced event; LRI = lower rate interval

A. F. Sinnaeve

DISLODGMENT OF THE ATRIAL LEAD INTO THE RIGHT VENTRICLE



PART 4

SOME IMPORTANT QUESTIONS :

1/ Does Ap capture the ventricle ?

2/ Does the ventricular-paced QRS configuration in the 12-lead ECG match the one recorded during VVI pacing ?

3/ What is being sensed by the displaced atrial electrode ?

4/ Does the pacemaker have a ventricular safety pacing (VSP) function ?

5/ Is the VSP function activated ?

A. F. Sinnaeve

They say I'm a real dummy, just because I've interchanged a couple of wires

REVERSED CONNECTION OF ATRIAL AND VENTRICULAR LEADS

AUTOMATIC MODE SWITCHING
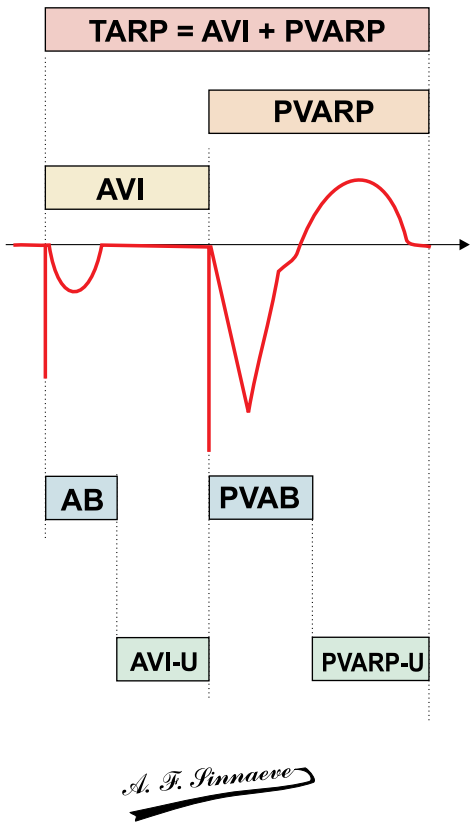
BLANKED and UNBLANKED PARTS of the ATRIAL REFRACTORY PERIODS



A. F. Sinnaeve

ATRIAL REFRACTORY INTERVALS

A signal falling in the refractory period can initiate neither an atrioventricular interval (AVI) nor a lower rate interval (LRI)

AVI = atrioventricular interval

PVARP = postventricular atrial refractory interval

TARP = total atrial refractory period

ATRIAL BLANKING INTERVALS

During these intervals the atrial channel is insensitive or blind to all signals.
By a special circuit, the electrogram can still be detected and displayed, but cannot influence the function of the pacemaker itself.

AB = atrial blanking period

PVAB = postventricular atrial blanking

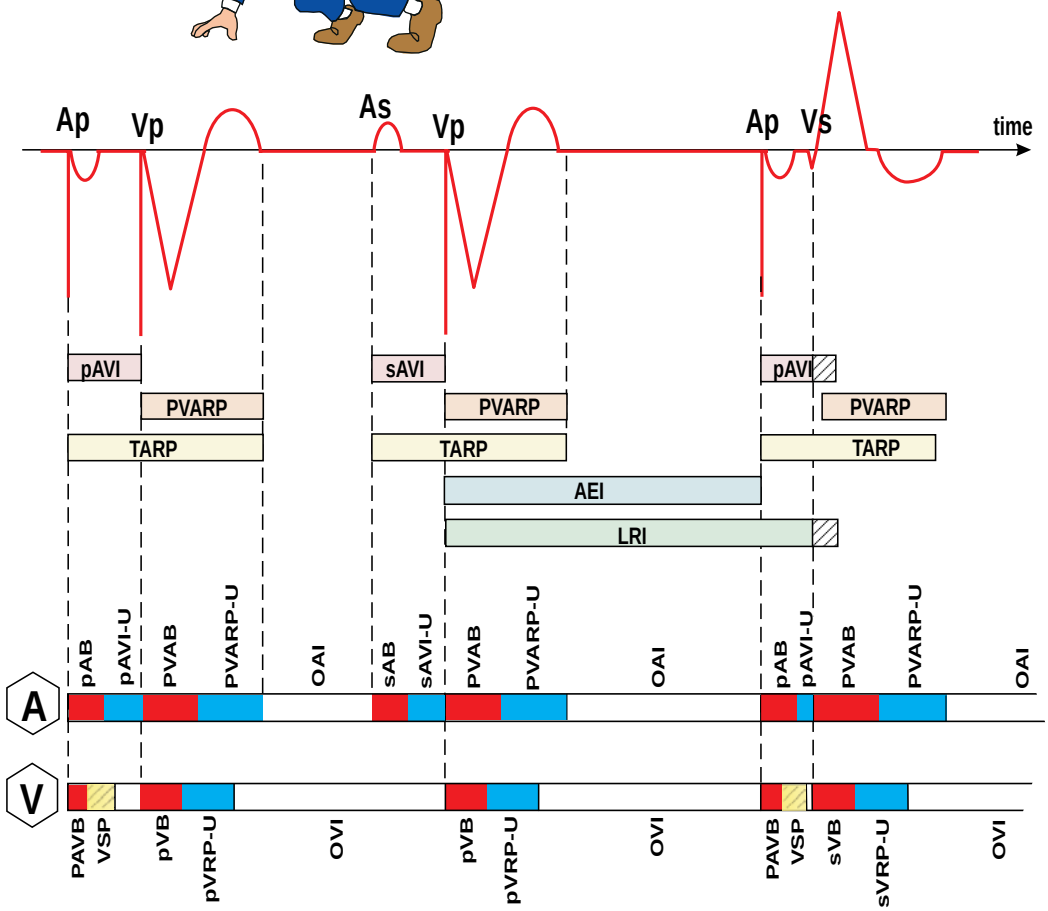
UNBLANKED ATRIAL REFRACTORY PERIODS

During these intervals signals can be sensed by the atrial channel and used to alter certain pacing timing cycles including the automatic mode switching (AMS), although they are unable to start an AVI or LRI.
Refractory sensed signals are depicted differently by the marker channel (Ar or AR).

AVI-U = unblanked atrioventricular interval

PVARP-U = unblanked postventricular atrial refractory interval

DIAGRAMMATIC REPRESENTATION OF TIMING CYCLES OF A DUAL CHAMBER PACEMAKER WITH AUTOMATIC MODE SWITCHING CAPABILITY



Abbreviations : Ap = atrial paced event; As = atrial sensed event; pAVI = paced atrioventricular interval; sAVI = sensed atrioventricular interval; AB = blanked first part of AVI; AVI-U = unblanked last part of AVI; PVAB = postventricular atrial blanking; PVARP = postventricular atrial refractory period; PVARP-U = unblanked second part of PVARP; TARP = total atrial refractory interval; AEI = atrial escape interval; OAI = open atrial interval;
Vp = ventricular paced event; Vs = ventricular sensed event; PAVB = postatrial ventricular blanking interval; VSP = ventricular safety pacing window ; VB = ventricular blanking period (p: after pacing - s: after sensing); VRP-U = unblanked ventricular refractory period; LRI = lower rate interval (ventricular timing); OVI = open ventricular interval

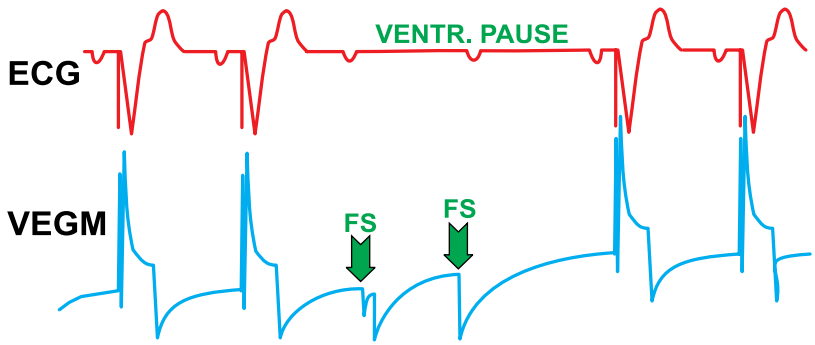
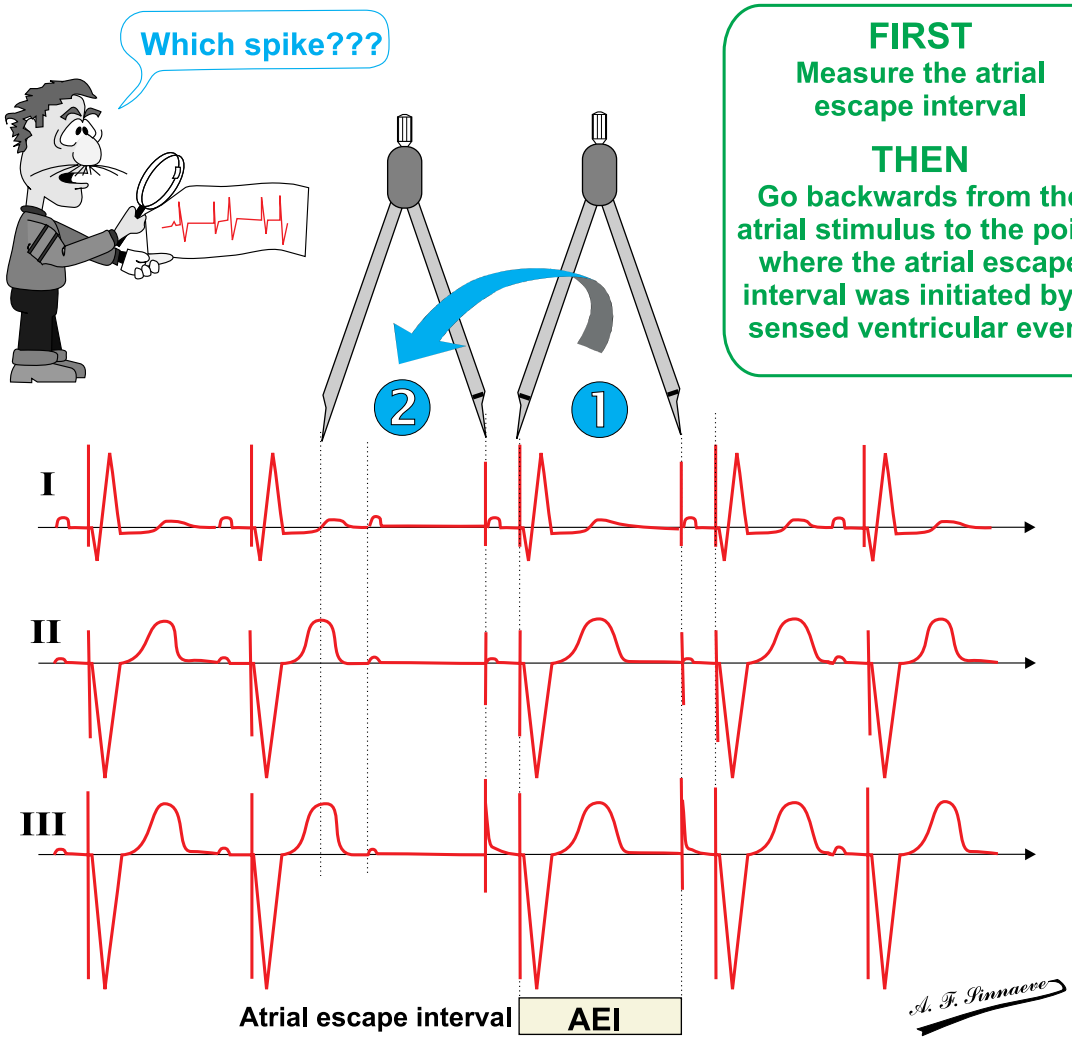
OVERSENSING

* What does the pacemaker sense ?
* False signals
* Mechanism of false signals
* Interaction of two leads with false signals



A. F. Sinnaeve

WHAT DOES THE VENTRICULAR CHANNEL OF THE PACEMAKER SENSE ?
T wave, afterpotential, false signal, … ?



FIRST
Measure the atrial escape interval

THEN
Go backwards from the atrial stimulus to the point where the atrial escape interval was initiated by a sensed ventricular event

* In ventricular-based sensing, the atrial escape interval (AEI) always remains constant.
* Measure backwards from an atrial stimulus to the preceding point of sensing because a ventricular event (paced or sensed) always initiates an AEI

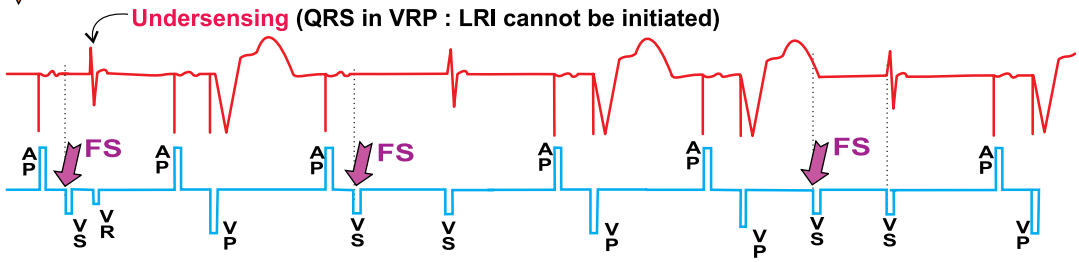
This method cannot be used in pacemakers with atrial-based lower rate timing

FALSE SIGNALS
FROM INTERMITTENT DERANGEMENT OF LEAD FUNCTION

Abrupt and large changes in resistance within a pacing system can cause corresponding voltage changes between the electrodes. These signals are called “false signals” or transients.

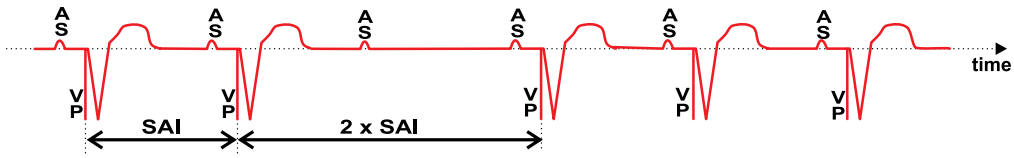
* These signals may be quite large but are almost always not seen on the surface ECG
* The usual causes are lead fractures and insulation defects
* False signals usually occur at random. Long rhythm strips will show the irregularirty of the abnormality with pauses of varying duration
* Oversensing of false signals is the great imitator of pacing

1 OVERSENSING OF FALSE SIGNALS CAN CAUSE UNDERSENSING



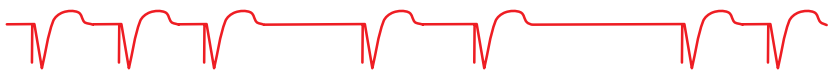
Erratic pacemaker behavior with pauses of varying duration and occasional undersensing strongly suggests a defective lead system creating false signals

2 THE PAUSES MAY BE EXACT MULTIPLES OF THE SINUS INTERVAL DURING SENSED SINUS RHYTHM



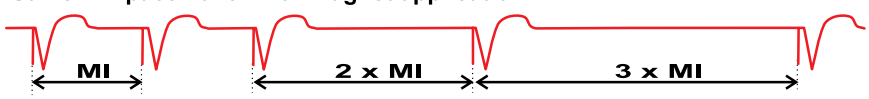
3 APPLICATION OF THE MAGNET CONVERTS IRREGULAR PAUSES TO A SITUATION WITH PAUSES OF REGULAR DURATION THAT ARE AN EXACT MULTIPLE OF THE MAGNET INTERVAL (DIAGNOSTIC OF LEAD FRACTURE)

VVI pacemaker without a magnet



A. T. Sinnaeve

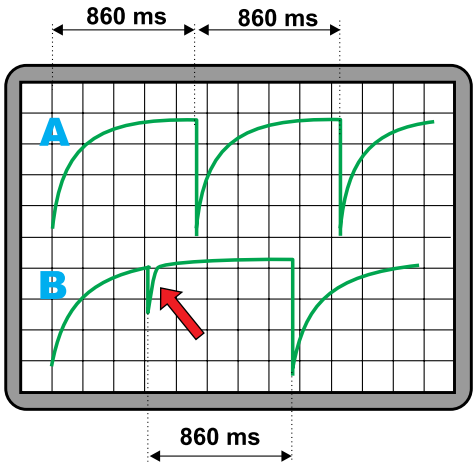
Same VVI pacemaker with magnet application



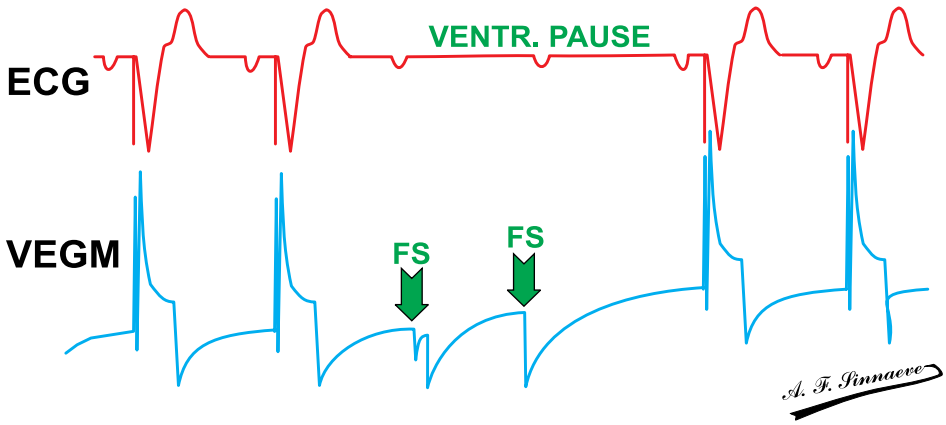
A lead problem can resemble T wave oversensing if mechanical systole creates false signals (making and breaking the circuit) only at a specific part of the cardiac cycle. Such an abnormality can be identical to T wave sensing even after application of the magnet. The diagnosis can be made by the configuration of the false signal in the telemetered EGM

Abbreviatons : AP = atrial pace; AS = atrial sense; FS = false signal; MI = magnet interval; SAI = spontaneous atrial interval; VP = ventricular pace; VS = ventricular sense; VR = ventricular sense in refractory period; LRI = lower rate interval

MECHANISM OF FALSE SIGNALS FROM INTERMITTENT CIRCUIT DISRUPTION



Voltage waveforms on an oscilloscope of a VVI pacemaker connected to a pacing lead in normal saline solution. The recording shows the mechanism of production of "false signals" from intermittent derangement of the pacemaker circuit. A shows an automatic interval of 860ms. In B, a false signal is deliberately created by manually breaking the connection between pacemaker and electrode for an instant. The disturbance causes a rapidly rising voltage of almost 200mV, well outside the refractory period of the pacemaker, which therefore senses it and recycles with an escape interval of 860ms. The reciprocal signal, caused by the return of voltage to the "baseline", because it occurs about 100ms after the initial signal, falls inside the refractory period of the pacemaker. Consequently it is not sensed.



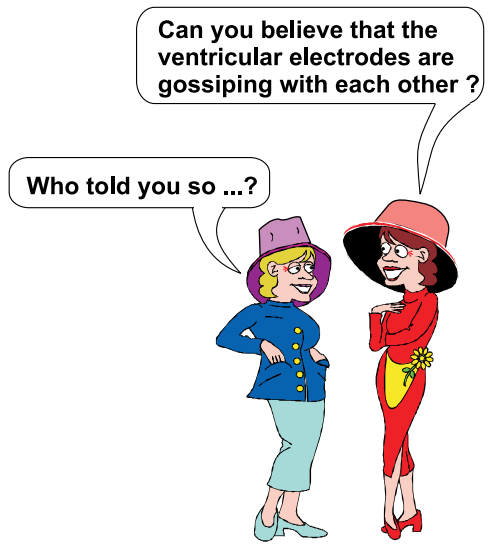
LEAD PROBLEMS CREATE FALSE SIGNALS

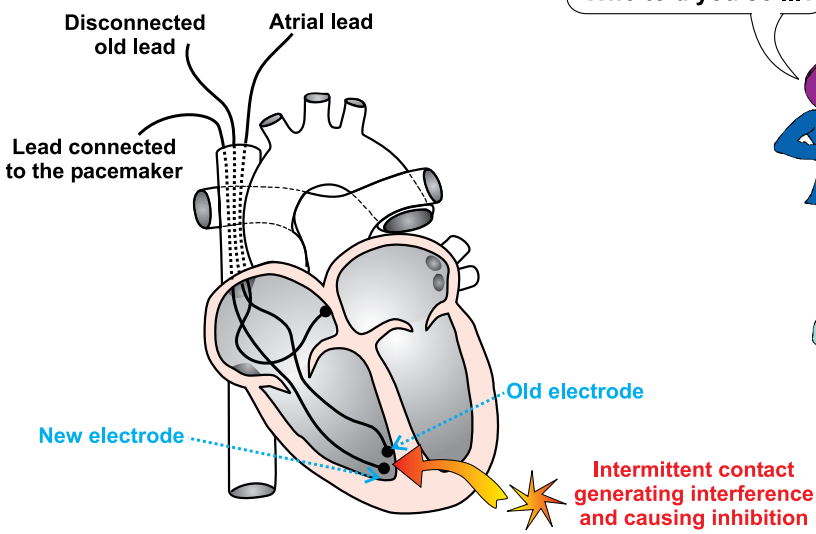
LEAD FRACTURE

INSULATION DEFECT

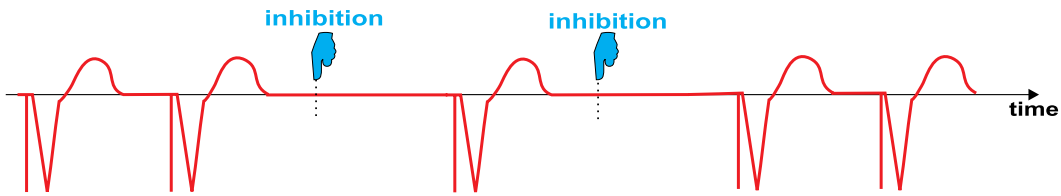
Abbreviations : ECG = surface electrocardiogram ; VEGM = ventricular electrogram ; FS = false signal

INTERACTION OF ACTIVE AND INACTIVE ELECTRODES LYING SIDE-BY-SIDE

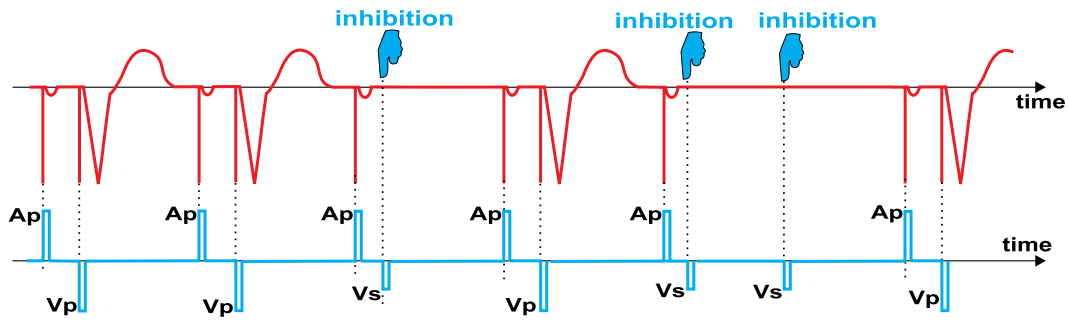




IN A VVI PACEMAKER

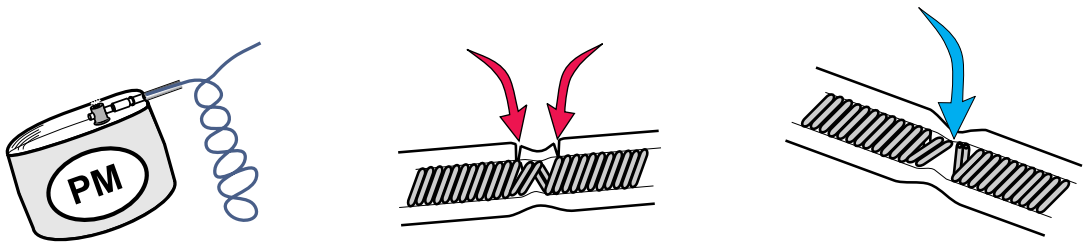


IN A DDD PACEMAKER



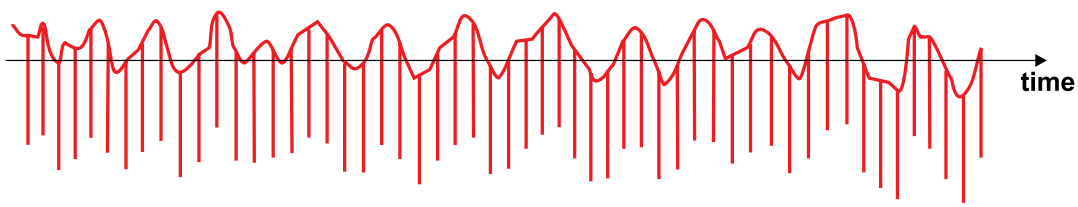
* Application of the magnet over the pacemaker eliminates the pauses related to oversensing and restores regular pacing at magnet rate.
* The false signals created by intermittent contact of the electrodes are invisible on the surface ECG. However, they can be seen in the intracardiac electrogram transmitted by telemetry.

A. F. Sinnaeve



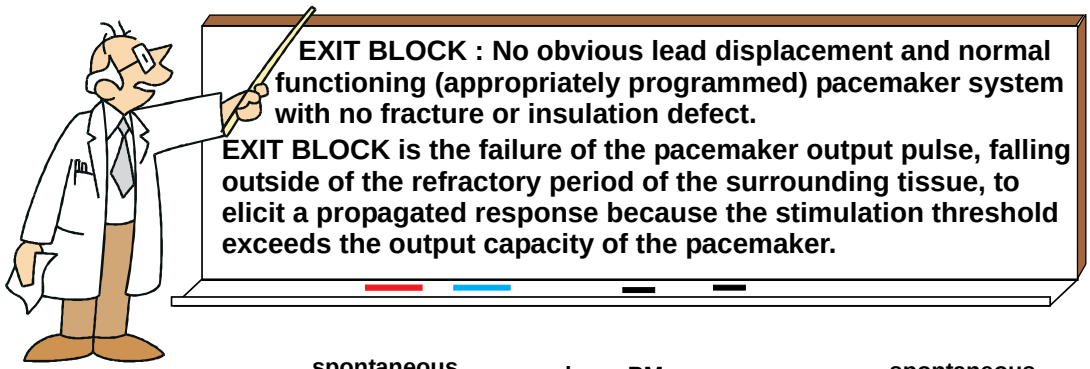
TROUBLESHOOTING

* High threshold - Exit block
* Loss of ventricular capture by visible pacemaker stimuli
* Missing stimuli during VVI pacing
* Lead insulation defect
* Lead fracture
* Analysis of lead problems
* Lead fracture - Conversion from bipolar to unipolar
* Subclavian crush syndrome
* Twiddler's syndrome
* Diaphragmatic stimulation
* Muscle stimulation
* Runaway pacemaker



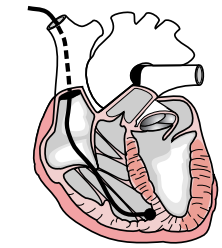
A. F. Sinnaeve

HIGH THRESHOLD - EXIT BLOCK

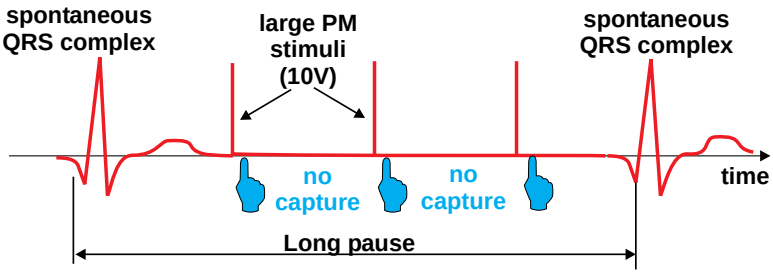


EXIT BLOCK : No obvious lead displacement and normal functioning (appropriately programmed) pacemaker system with no fracture or insulation defect.

EXIT BLOCK is the failure of the pacemaker output pulse, falling outside of the refractory period of the surrounding tissue, to elicit a propagated response because the stimulation threshold exceeds the output capacity of the pacemaker.



properly positioned electrode



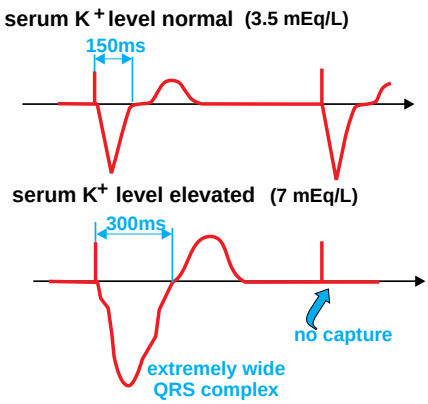
CAUSES :

* excessive tissue reaction around the lead tip
* various antiarrhythmic drugs (e.g. flecainide)
* electrolyte abnormality (e.g. hyperkalemia, acidosis and hypothyroidism)
* myocardial infarction & tissue damage from defibrillation, electrocautery and radiotherapy

HYPERKALEMIA

AN ELEVATED POTASSIUM LEVEL CAUSES :

* disappearance of P waves due to atrial asystole
* very wide QRS complexes (up to 3OOms)
* pacemaker exit block



A. F. Sinnaeve

LOSS OF VENTRICULAR CAPTURE BY VISIBLE PACEMAKER STIMULI

1 FUNCTIONAL

- ✓ Normal situation : stimuli in myocardial refractory period.

2 ELECTRODE-TISSUE INTERFACE

☞ LEAD DISPLACEMENT

- ✓ Early displacement or unstable position of pacing leads (commonest cause).
- ✓ Malposition into the coronary venous system.
- ✓ Twiddler's syndrome causing late displacement.
- ✓ Perforation of right ventricle by ventricular lead.

☞ NO APPARENT LEAD DISPLACEMENT

- ✓ Microdislodgment (a diagnosis of exclusion) causes a marked rise in capture threshold but displacement is not apparent on a chest x-ray.
- ✓ Elevated pacing threshold without obvious lead displacement (exit block) : Acute or chronic reaction at the electrode-tissue interface.
- ✓ Subcutaneous emphysema.
- ✓ Myocardial infarction or ischemia, hypoxia.
- ✓ Hypothyroidism.
- ✓ Elevation of pacing threshold after defibrillation or cardioversion. This is usually transient for a few minutes or less.
- ✓ Electrolyte abnormalities usually hyperkalemia, severe acidosis.
- ✓ Drug effect : Flecainide and propafenone can elevate the pacing threshold with therapeutic doses.

3 ELECTRODE

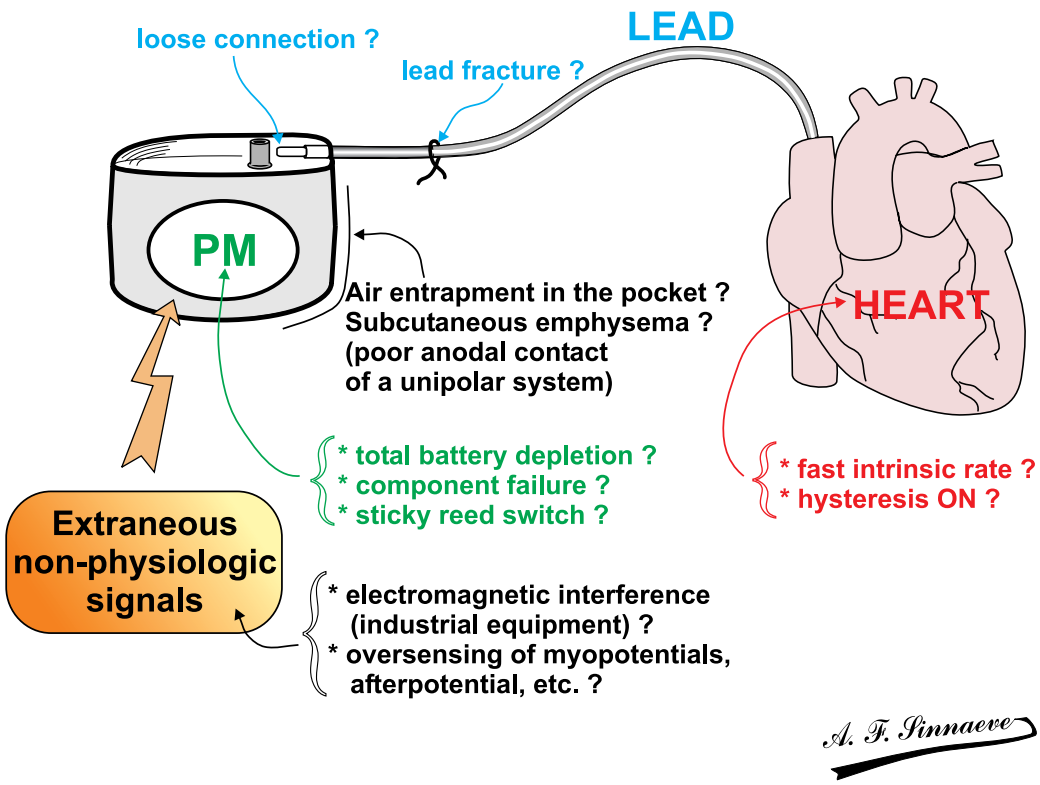
- ✓ Fracture, short circuit or insulation break.

4 PULSE GENERATOR

- ✓ Normal pacemaker with incorrect programming of parameters.
- ✓ Pacemaker failure from exhaustion or component failure.
- ✓ Iatrogenic causes : Component failure after defibrillation, electrocautery and therapeutic radiation.

A. F. Sinnaeve

CAUSES OF MISSING STIMULI DURING VVI PACING

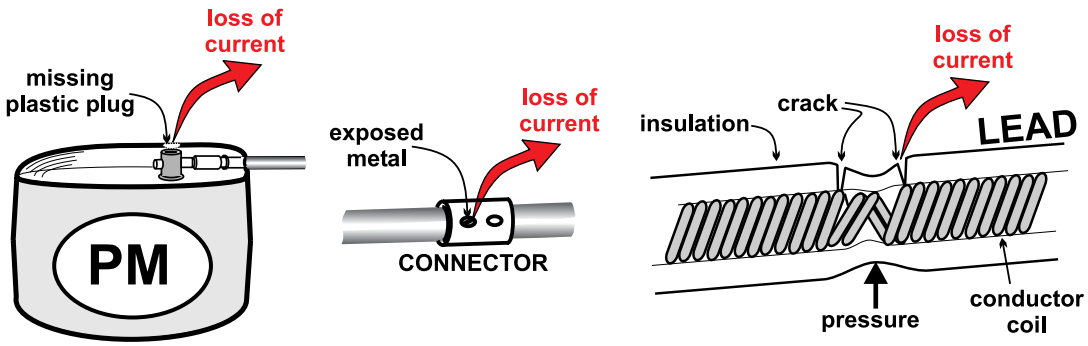


A. F. Sinnaeve

!!!

Pseudomalfunction : when overlooking the tiny bipolar pacemaker stimuli on the surface ECG

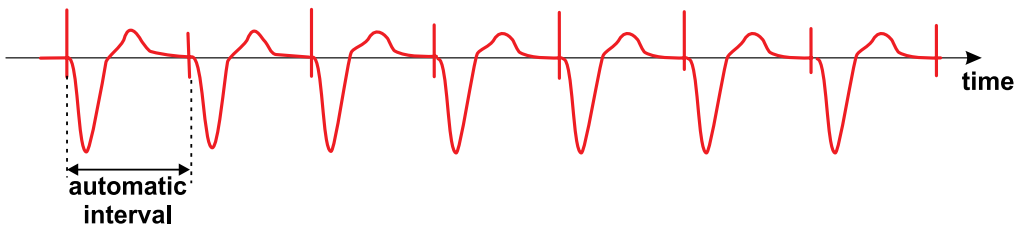
LEAD INSULATION DEFECTS



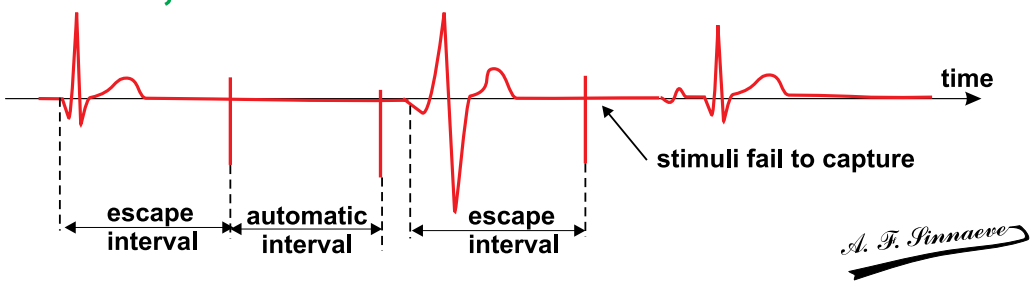
POSSIBLE CONSEQUENCES

* pacing may or may not be preserved
* stimuli are always present
* the pacing impedance is decreased
* excessive current loss leads to premature battery depletion

PACING IS PRESERVED

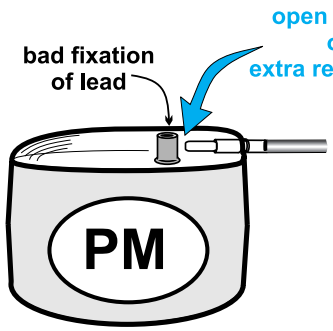


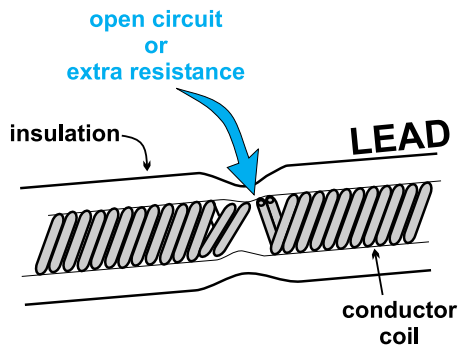
STIMULI, BUT FAIL TO CAPTURE



A. F. Sinnaeve

LEAD FRACTURE

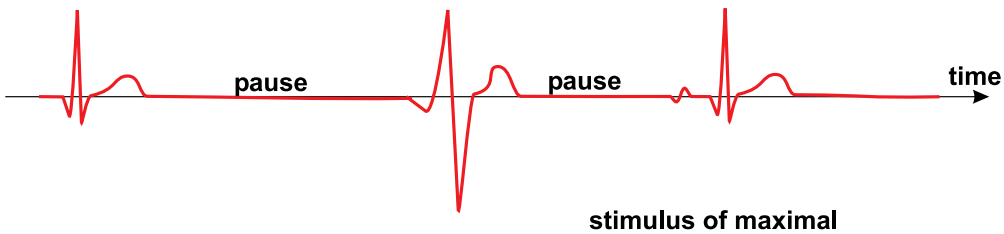




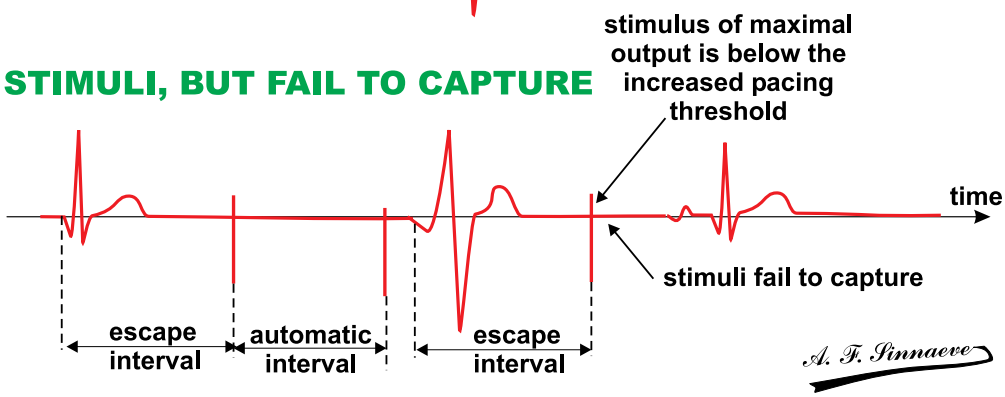
POSSIBLE CONSEQUENCES

* Stimuli may and may not be absent
* The voltage threshold is high
* The pacing impedance is increased

ALL STIMULI ABSENT



STIMULI, BUT FAIL TO CAPTURE



A. F. Sinnaeve

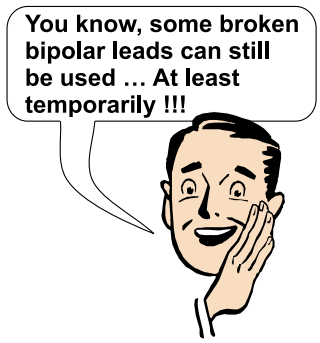
ANALYSIS OF LEAD PROBLEMS

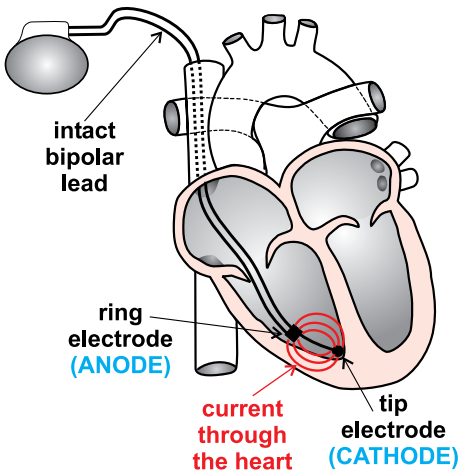
Be cunning as a fox ! You can get a lot of information about the leads, just by looking at the pacing impedance and the voltage threshold. The secret is to look at both !

	IMPEDANCE	VOLTAGE THRESHOLD
NORMAL LEAD PLACEMENT	NORMAL	NORMAL
LEAD DISPLACEMENT OR EXIT BLOCK	NORMAL	HIGH
LEAD FRACTURE	HIGH	HIGH
LEAD INSULATION DEFECT	LOW	MAY BE MODERATELY INCREASED

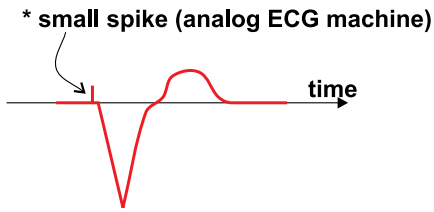
A. F. Sinnaeve

LEAD FRACTURE WITH CONVERSION FROM BIPOLAR TO UNIPOLAR MODE

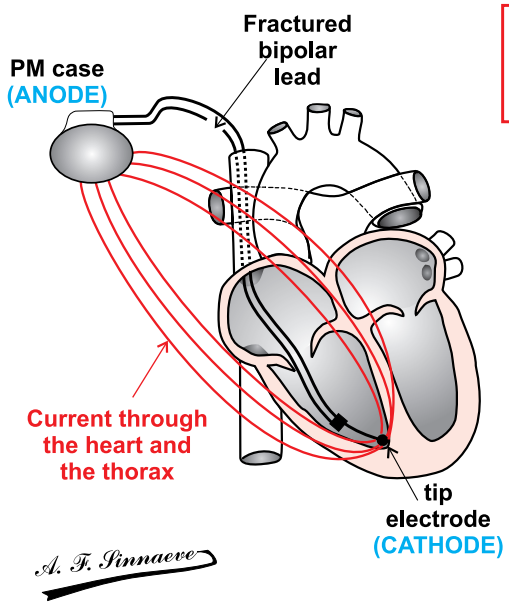




NORMAL BIPOLAR STIMULATION



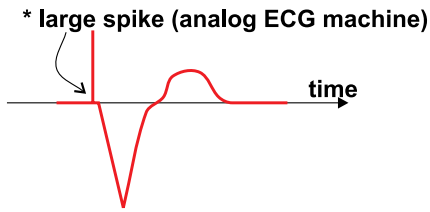
* normal pacing impedance
(Z = about 500 ohm)



A. F. Sinnaeve

If one of the conductors in the bipolar lead is fractured, the pacing impedance becomes high !!!

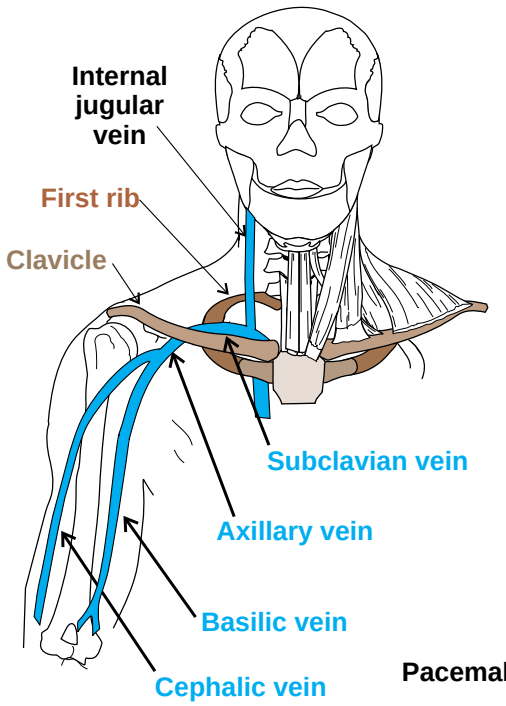
UNIPOLAR STIMULATION (via the distal tip electrode of a bipolar lead)

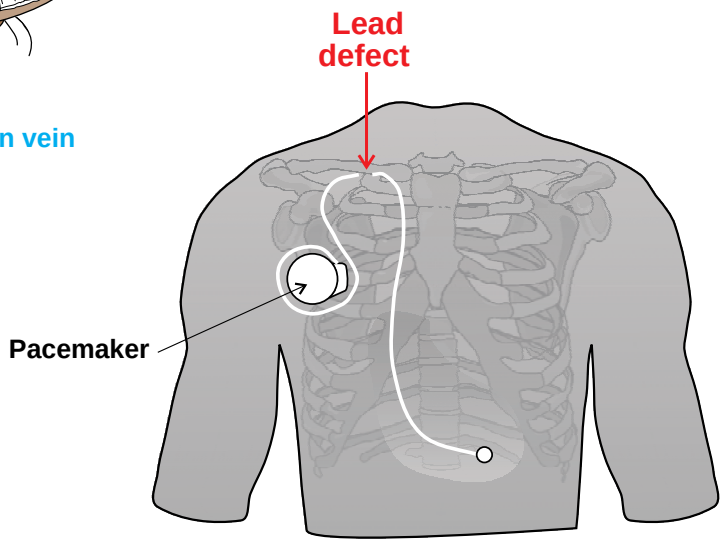


* normal pacing impedance
(Z = about 500 ohm)

Some contemporary pacemakers can measure lead impedance periodically and store the data which can be eventually retrieved by telemetry.
Some pacemakers are designed to detect the high impedance of an electrode fracture whereupon the device automatically converts its function from the bipolar to the unipolar mode of pacing and sensing (using the intact electrode as the cathode).
During follow-up, application of a magnet will temporarily restore bipolar function with resultant loss of capture.

SUBCLAVIAN CRUSH SYNDROME





DEFINITION :

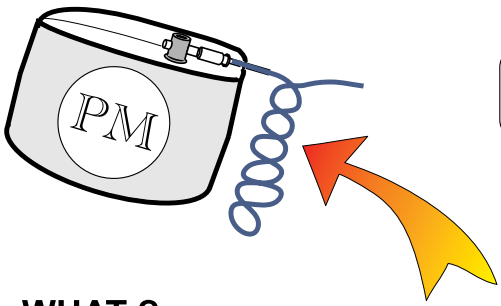
The subclavian crush syndrome is described with pacemaker leads implanted via subclavian puncture. This may occur when conductor fractures and insulation breaches develop by compression of a lead between the first rib and the clavicle.

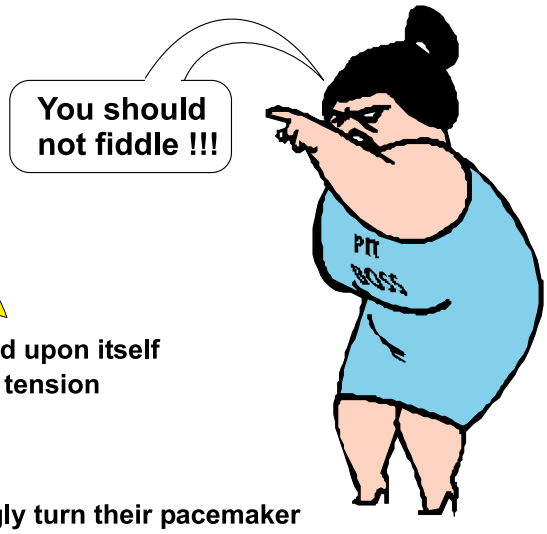
PREVENTION :

The subclavian crush syndrome occurs when the puncture is too medial and may be avoided by a more lateral subclavian puncture or by using the axillary vein or even the cephalic vein.

A. F. Sinnaeve

TWIDDLER'S SYNDROME





WHAT ? The lead is tightly twisted upon itself with the development of tension

CAUSES ?

* Elderly patients who unwittingly turn their pacemaker
* Obese patients with a loose pacemaker pocket
* Excessively large pacemaker pocket

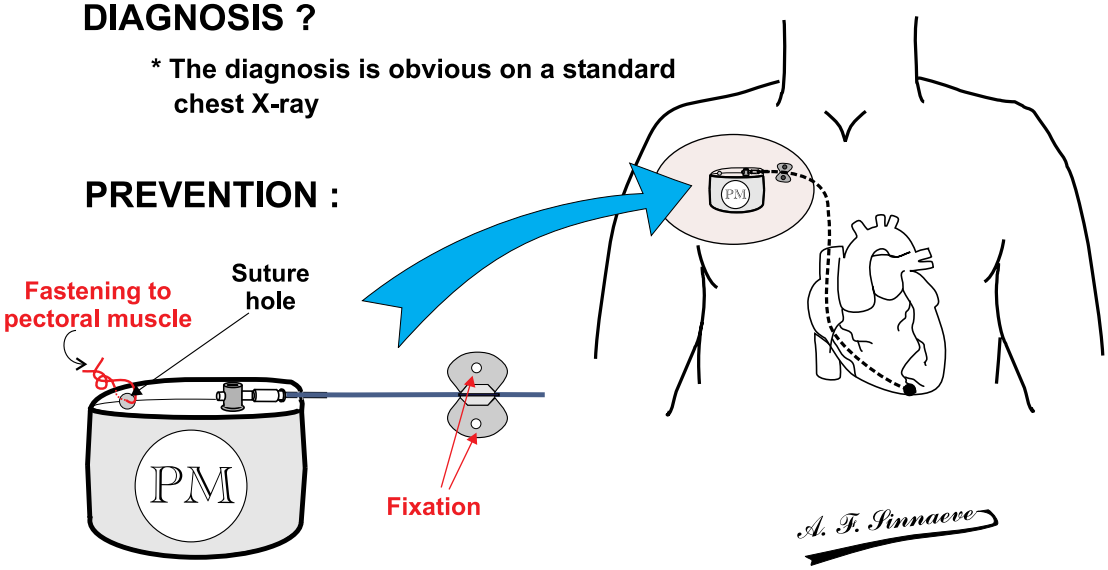
CONSEQUENCES ?

* Dislocation of the lead with failure to pace
* Lead fracture
* Insulation defect

DIAGNOSIS ?

* The diagnosis is obvious on a standard chest X-ray

PREVENTION :

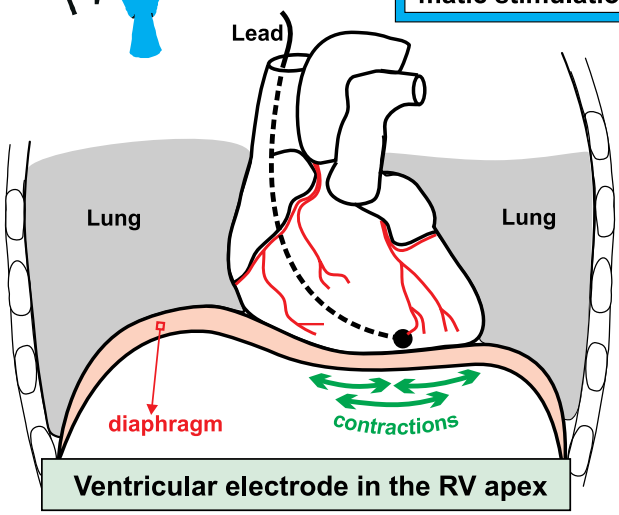


A. F. Sinnaeve

DIAPHRAGMATIC STIMULATION

WARNING

Always consider the possibility of RV lead perforation when left diaphragmatic stimulation is observed !



Ventricular electrode in the RV apex

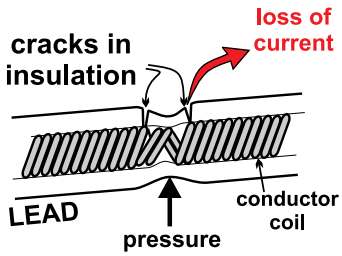
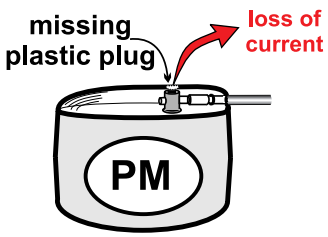
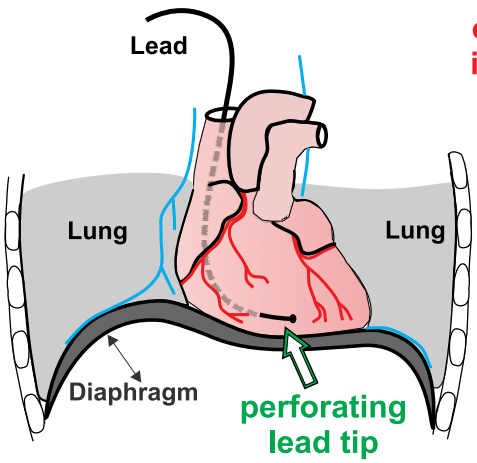
A. F. Sinnaeve

Abbreviations : RV = right ventricle ; LV = left ventricle

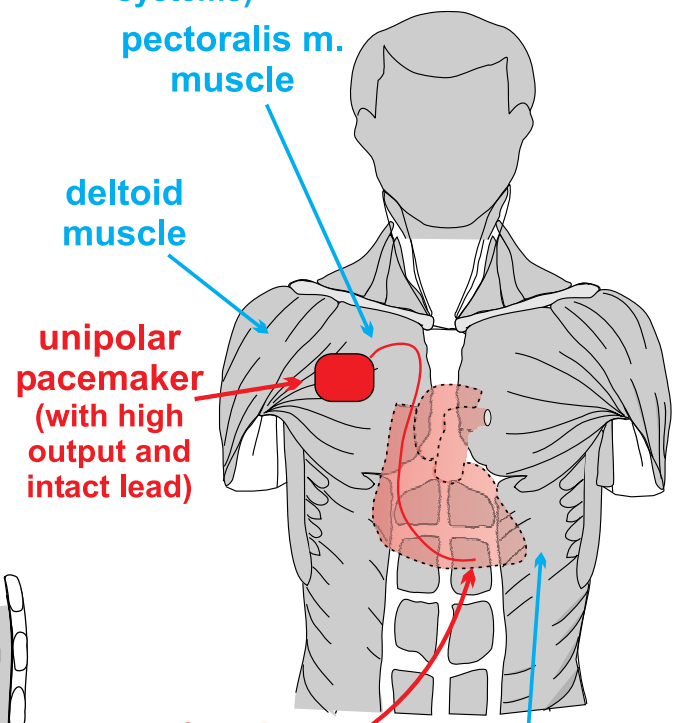
MUSCLE STIMULATION







(Extravascular lead insulation defect in unipolar or bipolar systems)

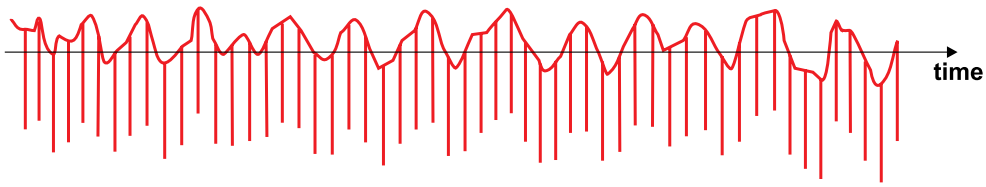


A. F. Sinnaeve

PACEMAKER RUNAWAY

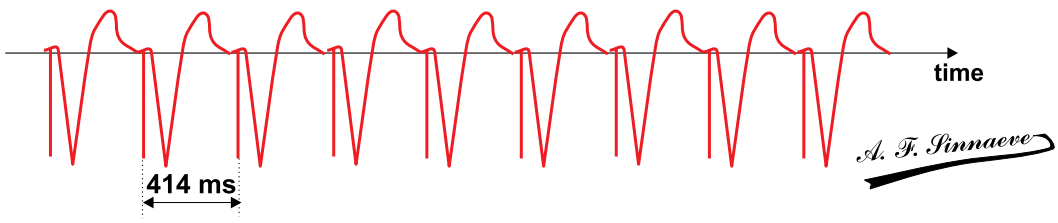
RUNAWAY OF AN OLD PACEMAKER AT 475 ppm

The VVI pacemaker emits stimuli at a rate of 475 ppm, too fast to cause 1:1 capture because of the ventricular myocardial refractory period. Such a situation may induce ventricular fibrillation. Emergency treatment consists of cutting the pacing lead.



RUNAWAY OF A RECENT VVI PACEMAKER

The pacemaker was programmed at 70 ppm and paced at 145 ppm.
(The patient presented with palpitations and dyspnea until the unit was removed)



Runaway is a serious component malfunction of pacemakers. It is now rare because of improved technology. All contemporary pacemakers are equipped with a "runaway protection circuit", usually limiting the maximum pacing rate to 150 - 180 bpm.

PACEMAKER HEMODYNAMICS & RATE-ADAPTIVE PACING

A. F. Sinnaeve

This is basic ! Everybody must know that !!!

HEMODYNAMICS OF THE NORMAL HEART

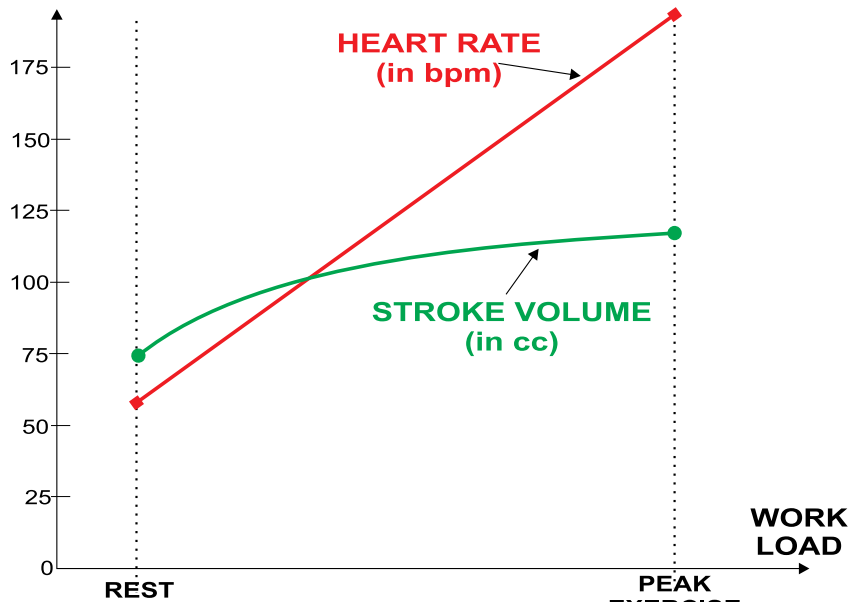
Heart Rate (HR) in bpm

Stroke Volume (SV) in liter per beat

Cardiac output (C.O.) in liter per minute

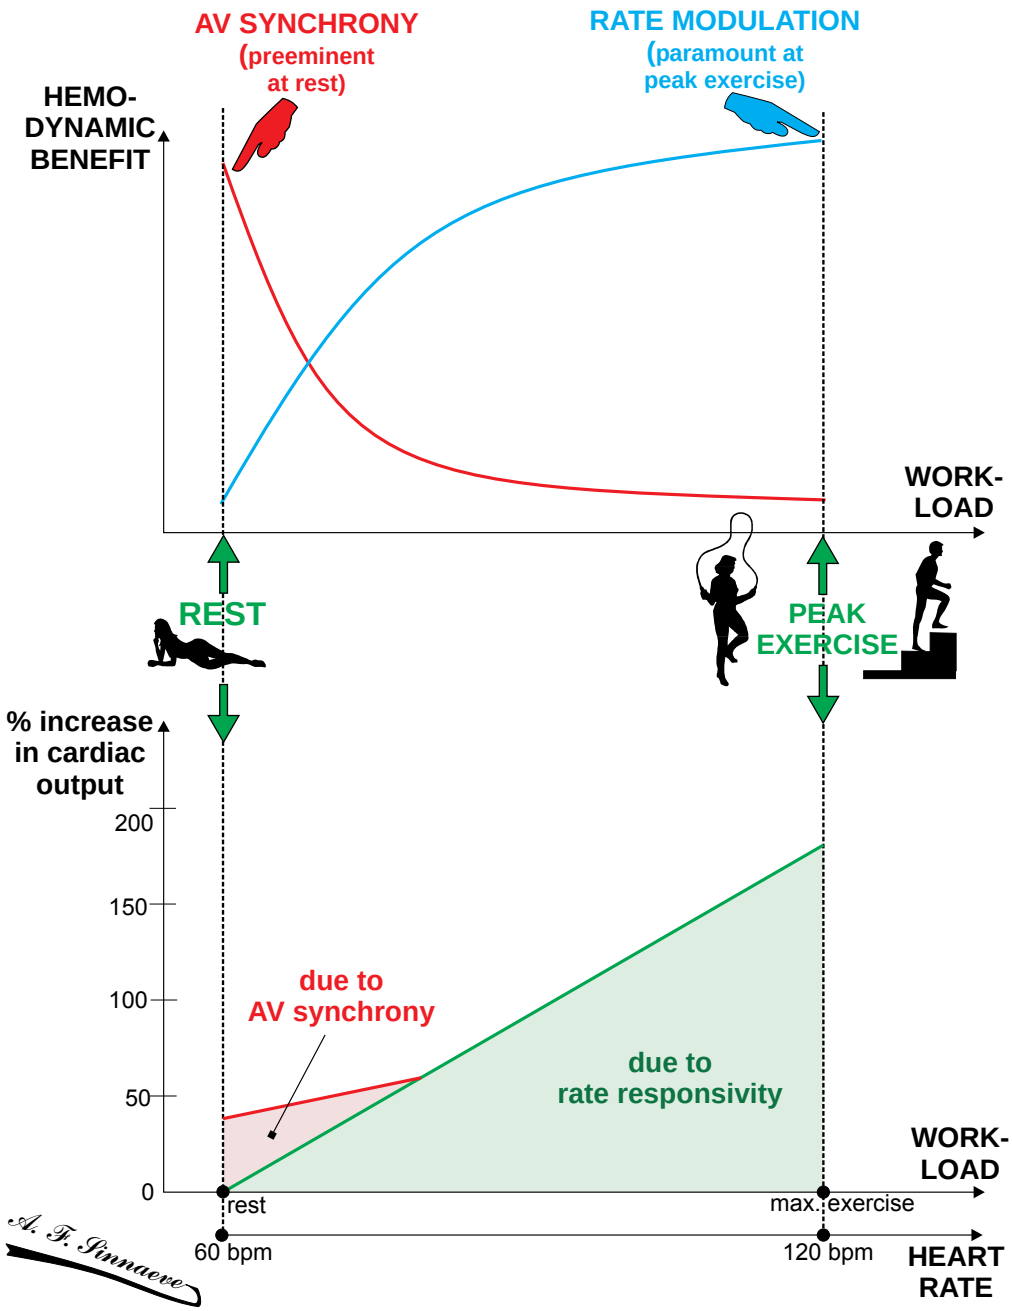
C.O. = HR x SV

$$\frac{\text{Liter}}{\text{Minute}} = \frac{\text{Beats}}{\text{Minute}} \times \frac{\text{Liter}}{\text{Beat}}$$

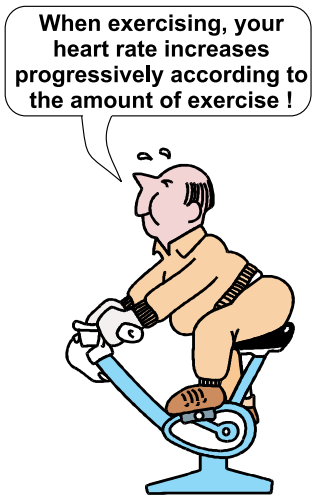


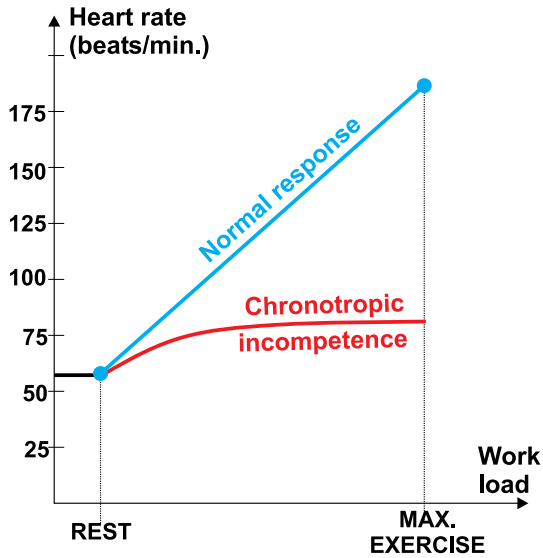
A. F. Sinnaeve

THE HEMODYNAMIC BENEFIT
AV SYNCHRONY VERSUS RATE MODULATION

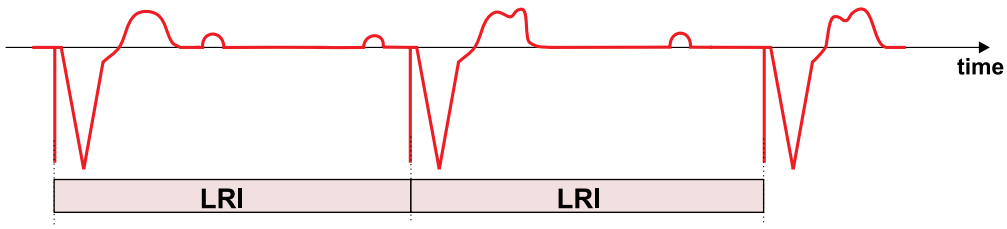


RATE - ADAPTIVE PACING AND CHRONOTROPIC INCOMPETENCE

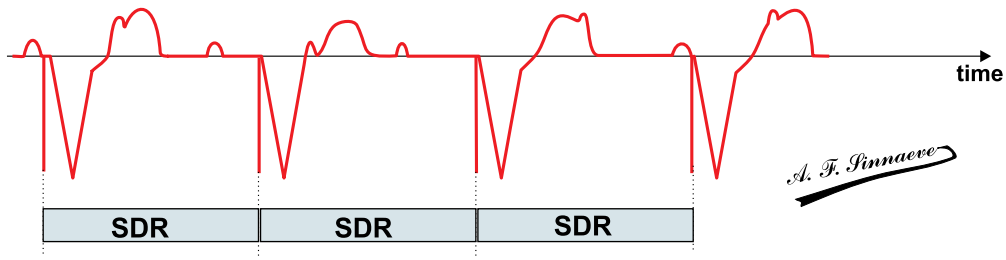




With a VVI pacemaker the ventricular pacing rate remains constant



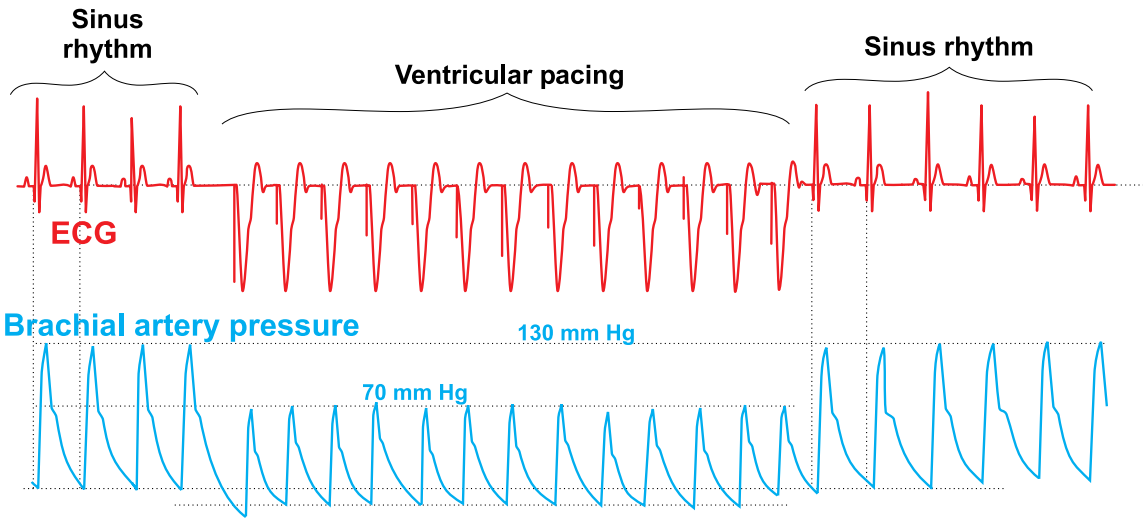
With a VVIR pacemaker the ventricular pacing rate increases when the workload increases



A. F. Sinnaeve

Abbreviations : LRI = lower rate interval ; SDR = sensor-driven interval

VVI PACING AND THE PACEMAKER SYNDROME



Blood pressure	=	Cardiac output	X	Peripheral resistance

or

BP = CO x PR

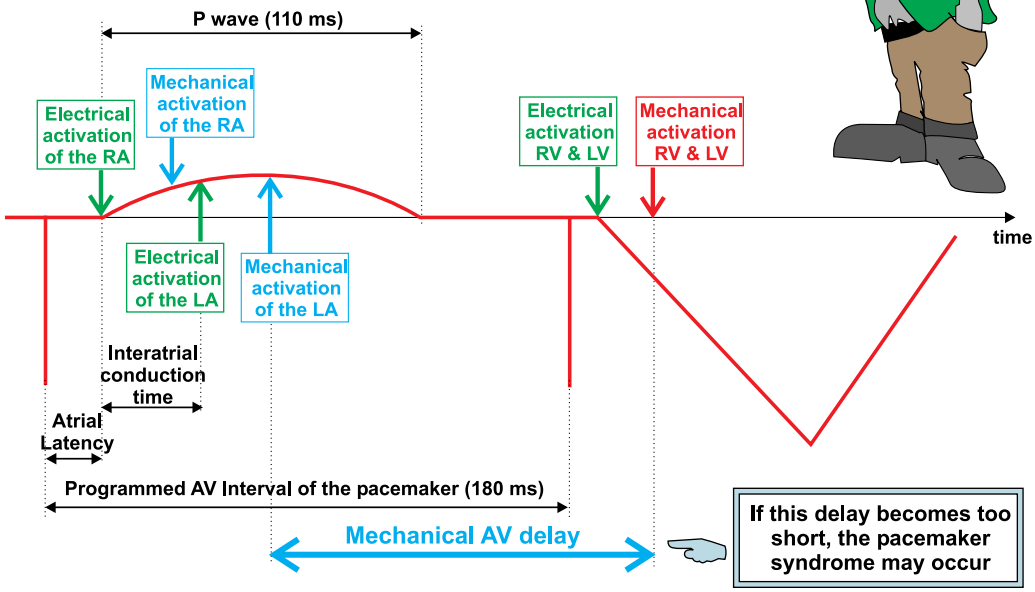
Normal : if CO↓↓↓ then PR↑↑↑ and BP ≅ constant

With pacemaker syndrome :
If CO↓↓↓ then PR↑↑ and BP↓

A. F. Sinnaeve

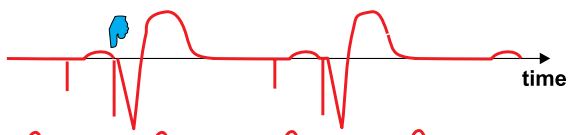
PACEMAKER SYNDROME WITH DUAL CHAMBER PACEMAKERS

The pacemaker syndrome refers to symptoms and signs present in the pacemaker patient which are caused by inadequate timing of atrial and ventricular contractions.

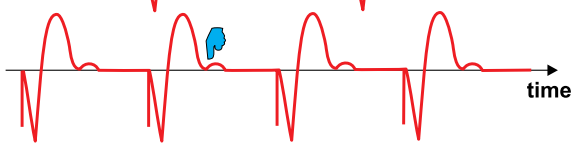


PM syndrome in atrial tracking pacemakers

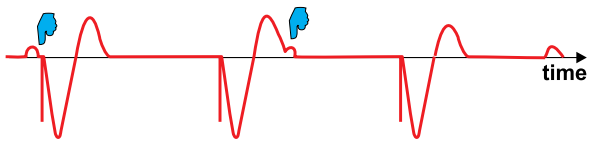
Marked delay of left atrial activation at rest and/or exercise



Sinus tachycardia with long programmed AV delay which does not shorten on exercise



VDD mode : sinus bradycardia at rest at a rate slower than the programmed lower rate



Repetitive nonreentrant VA synchrony

A. F. Sinnaeve

MAINTENANCE OF NORMAL VENTRICULAR DEPOLARIZATION

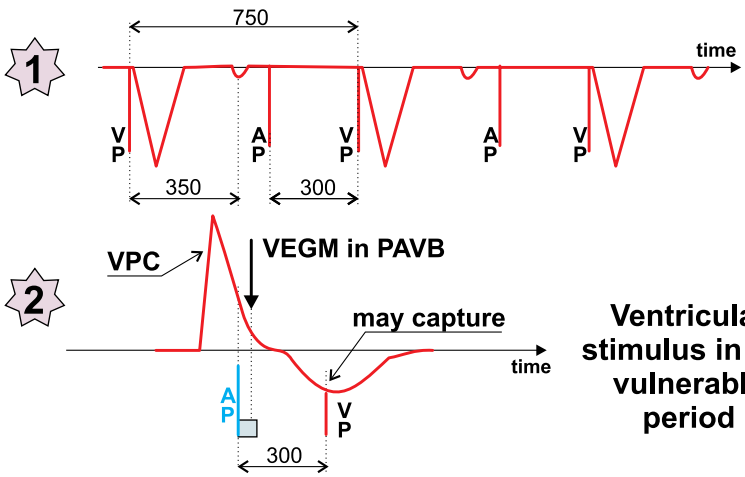
Ventricular depolarization via the normal pathway is hemodynamically superior to pacemaker induced depolarization on a short-term as well as on a long-term basis

Attempt to promote normal ventricular depolarization
if possible in specific circumstances, provided the PR interval remains shorter than 260 - 280 ms.

* AAI(R) mode . Risk of AV block !
* DDI(R) mode with long AV delay.
* DDD(R) mode with long AV delay.
* DDD(R) mode with AV search hysteresis or device with automatic switching to AAI(R) mode as required.

A long AV delay cannot always prevent pacemaker-induced ventricular depolarization in patients with normal AV conduction because of fusion and pseudo-fusion beats and other circumstances.

Risks of a long AV delay !!!

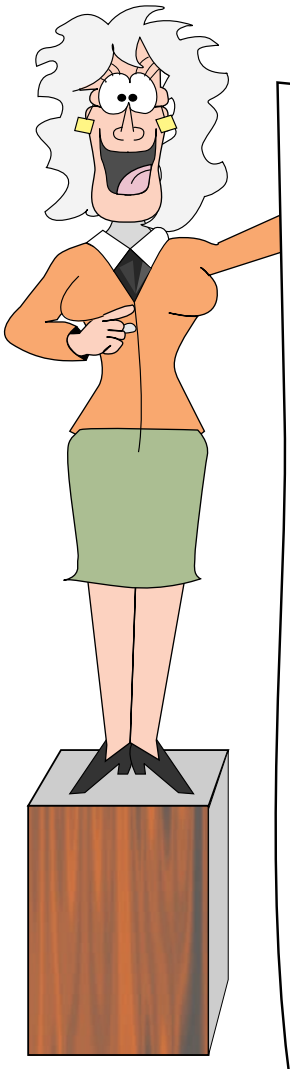


Repetitive nonreentrant VA synchrony (RNRVAS)

Ventricular stimulus in the vulnerable period

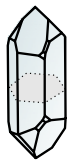
A. F. Sinnaeve

Abbreviations : AP = atrial pace; VP = ventricular pace; VPC = ventricular premature complex; VEGM = ventricular electrogram ; PAVB = postatrial ventricular blanking



INDICATORS FOR RATE-ADAPTIVE PACING

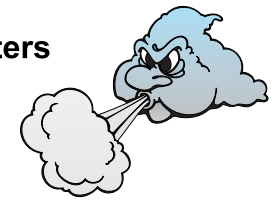
1. NON - PHYSIOLOGIC



* Vibration (Activity)
* Acceleration

2. PHYSIOLOGIC

A/ Non-cardiac parameters
Indirect metabolic



* Minute ventilation

B/ Cardiac parameters

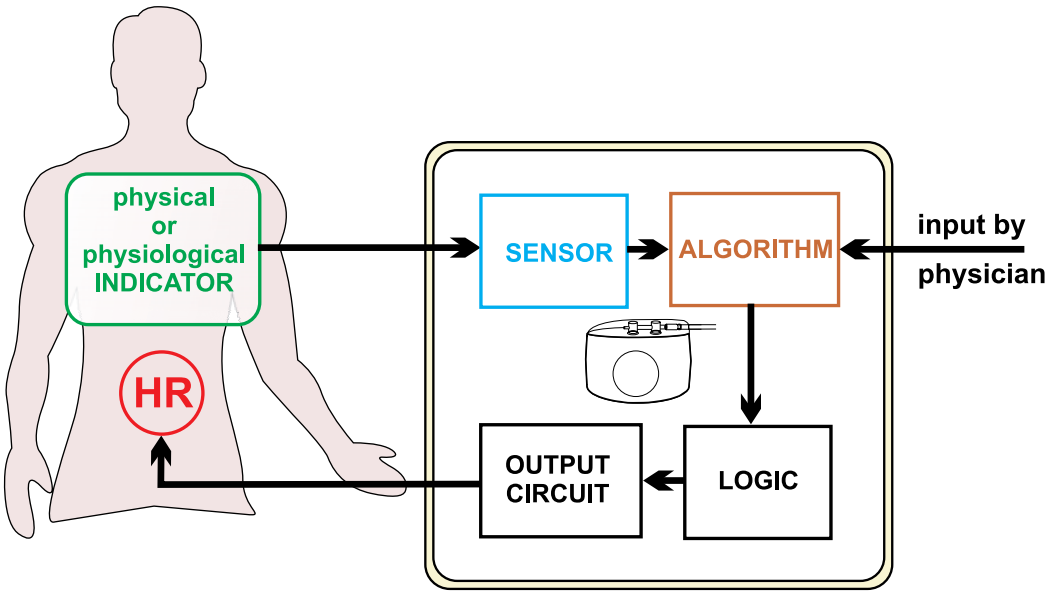
A. F. Sinnaeve

OPEN LOOP RATE - ADAPTIVE PM SYSTEM



HEART RATE (HR) :
The heart rate should be adapted to the need of the body

INDICATOR :
An indicator is a physical or physiological parameter, changing according to the metabolic needs of the body

SENSOR :
A sensor is a device that converts non-electrical data (i.e. an indicator) into electrical signals. The response of the indicator to the body function determines the magnitude and frequency of the electrical signals

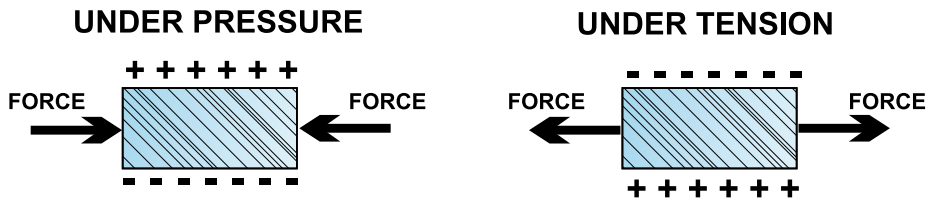
ALGORITHM :
The algorithm is the software function of the pacemaker that converts the electrical signals from the sensor into an appropriate pacing response by the device

A. F. Sinnaeve

SENSORS OF BODY MOTION

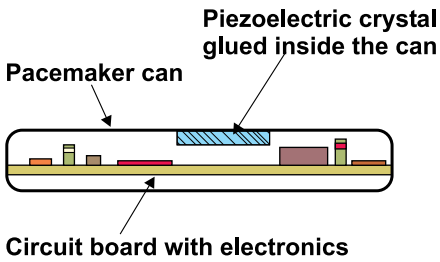
① THE PIEZOELECTRIC EFFECT

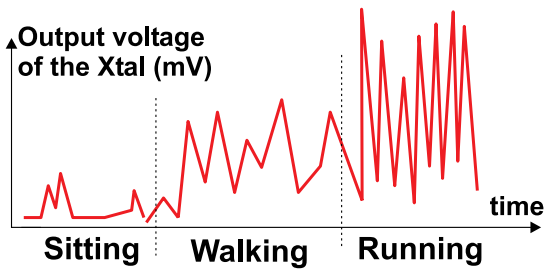
Some crystals (e.g. quartz) generate an electric voltage when they are subjected to mechanical stress.



② THE ACTIVITY SENSOR

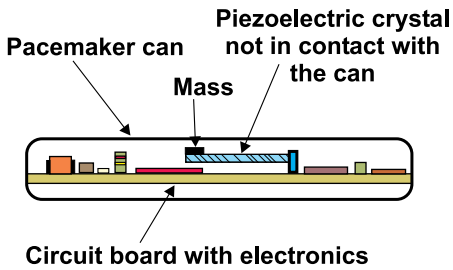
Responds to body vibrations.
Reacts to external stimuli that should not increase the pacing rate e.g. pressure on the device.





③ THE ACCELEROMETER

A very small mass in the pacemaker reacts upon acceleration and deforms the crystal which generates a voltage. This system has greater specificity than the activity sensor above, i.e. less false positive responses.

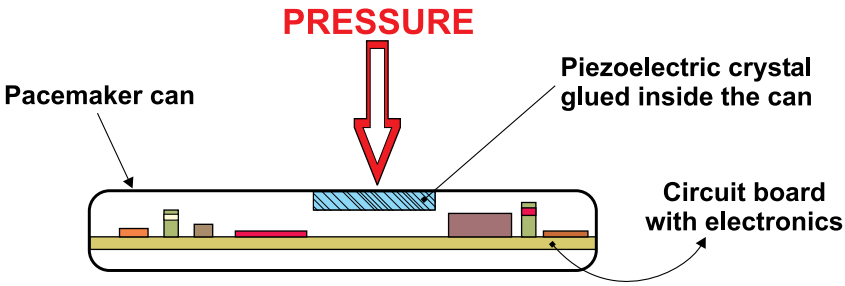


Both the activity sensor and the accelerometer react very fast upon the onset of any movement. The capability of early exercise detection makes the activity sensor a good component of dual sensor systems : e.g. activity + minute ventilation or activity + QT sensing

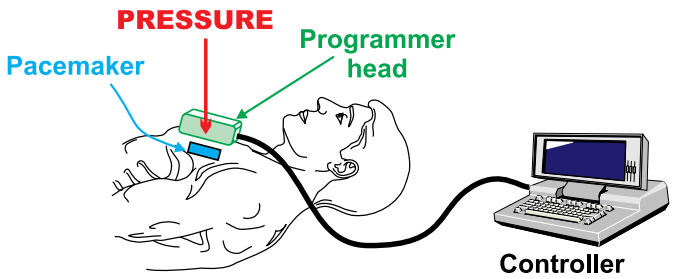
A. F. Sinnaeve

Abbreviations : mV = millivolt ; Xtal = crystal

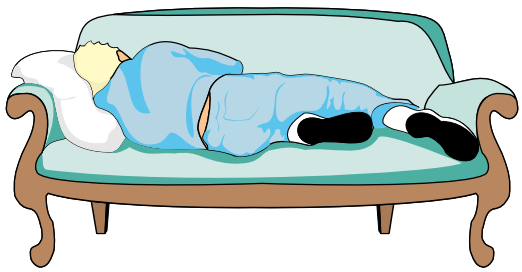
PRESSURE ON DEVICES EQUIPPED WITH AN ACTIVITY SENSOR



Since the crystal is in contact with the pacemaker can, pressure on the device may increase the heart rate without any exercise of the patient !!!



To avoid an increased rate, devices with an activity sensor should be reprogrammed temporarily to the DDD mode before testing the function of the pacemaker other than its rate-adaptive function.



Sleeping on one's abdomen may create pressure upon the pacemaker and increase the heart rate.
Even when the patient moves in bed, the pacing rate may go up.

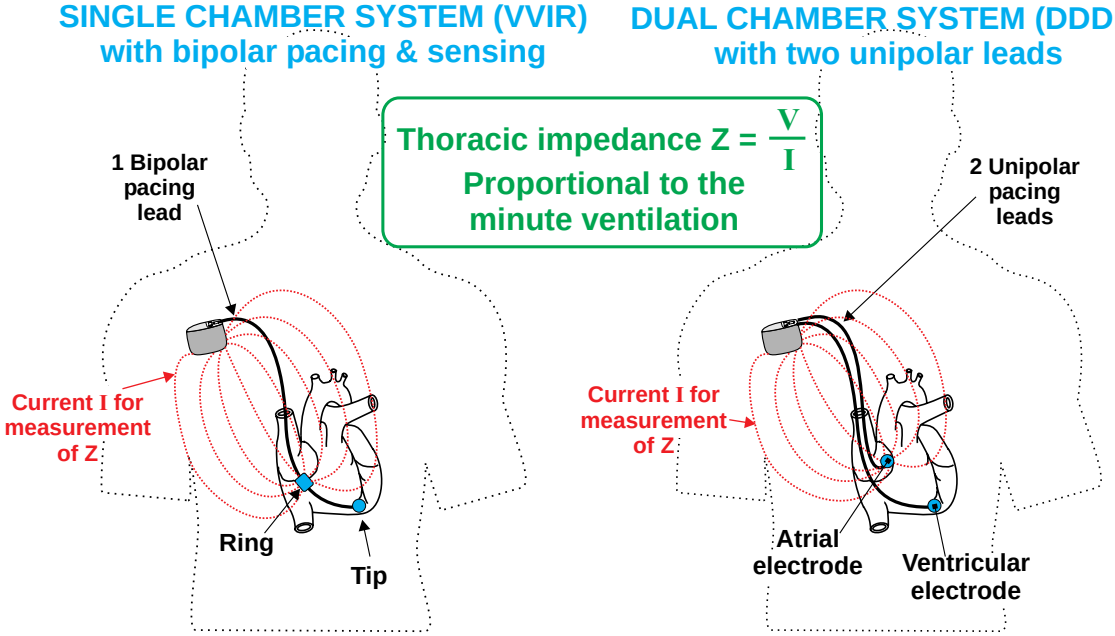
A. F. Sinnaeve

ARRANGEMENT OF MINUTE VENTILATION SENSORS

SINGLE CHAMBER SYSTEM (VVIR) with bipolar pacing & sensing

DUAL CHAMBER SYSTEM (DDDR) with two unipolar leads

Thoracic impedance Z = $\frac{V}{I}$
Proportional to the minute ventilation

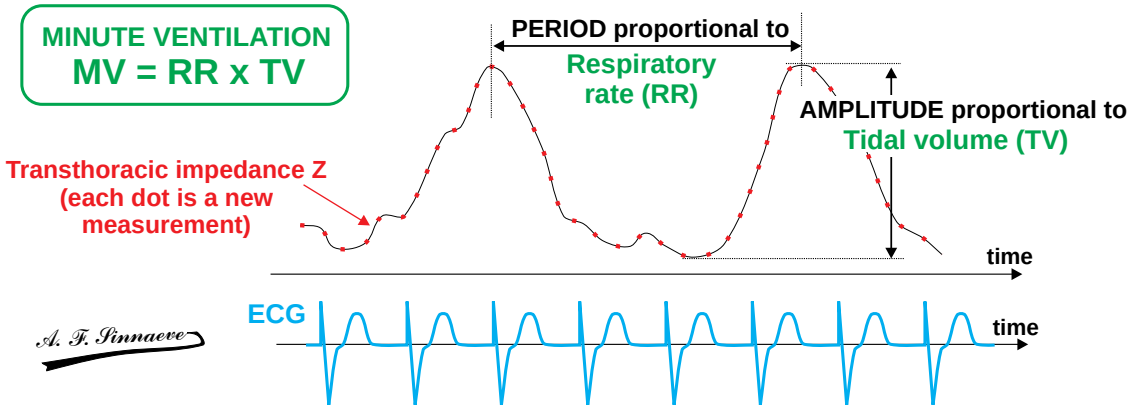


Current injection(I) between PM can and ring electrode
Voltage measurement (V) between PM can and tip electrode

Current injection(I) between PM can and atrial electrode
Voltage measurement (V) between PM can and ventricular electrode

* the current pulses I for impedance measurement are subthreshold, they have a low amplitude and are very short (pulse duration 5 to 15 μs)
* the measurement is frequently repeated (480 to 1200 times per minute)

MINUTE VENTILATION
MV = RR x TV



A. F. Sinnaeve

MINUTE VENTILATION SENSOR

Minute ventilation (liter/minute) = **Tidal volume (liter)** X **Respiratory rate (breaths/minute)**

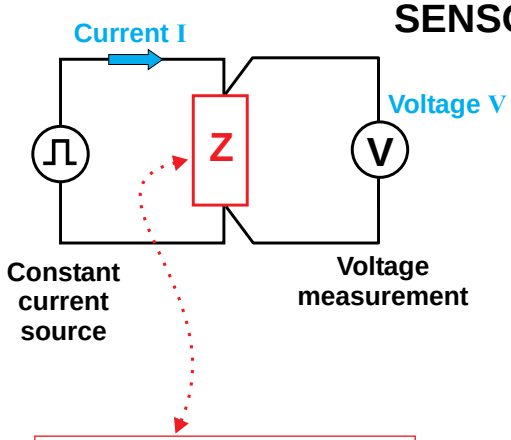
Tidal volume (liter) → **Amplitude of transthoracic impedance Z signal**

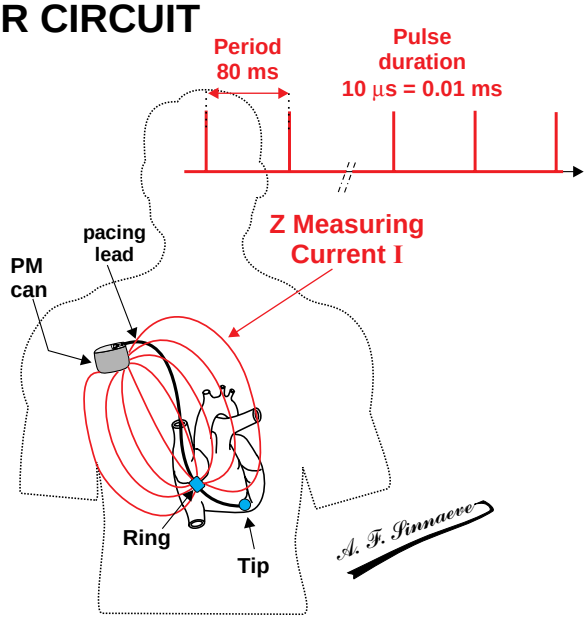
Respiratory rate (breaths/minute) → **Frequency of transthoracic impedance Z signal**

Amplitude of transthoracic impedance Z signal X **Frequency of transthoracic impedance Z signal** → **ALGORITHM (ampl. x freq.)**

A special circuit inside the pacemaker sends very short subthreshold current pulses I of known amplitude through the thorax. The device measures the voltage V between 2 thoracic sites as shown in the diagram below. This voltage is proporional to the transthoracic impedance Z

SENSOR CIRCUIT





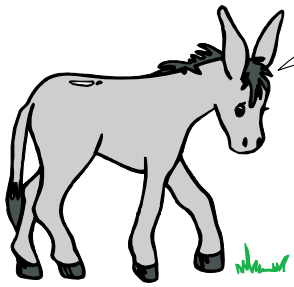
Thoracic impedance = $\frac{V}{I}$ = Z

FOR SENSOR FUNCTION

* Current I between can and ring electrode
* Voltage V between can and tip electrode

Movement of the arm may cause impedance changes and a faster pacing rate

MINUTE VENTILATION SENSOR - PART 2

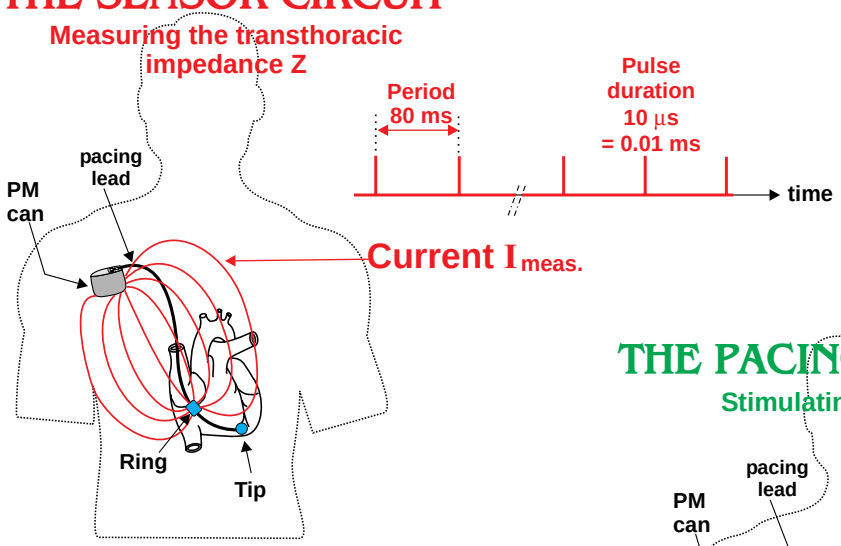


According to the engineers it's a piece of cake... and I don't even understand what they are talking about !!!
But I am only a little donkey...

NOTE THE DIFFERENCE !!!
THERE ARE 2 SEPARATE ELECTRIC CIRCUITS INVOLVED

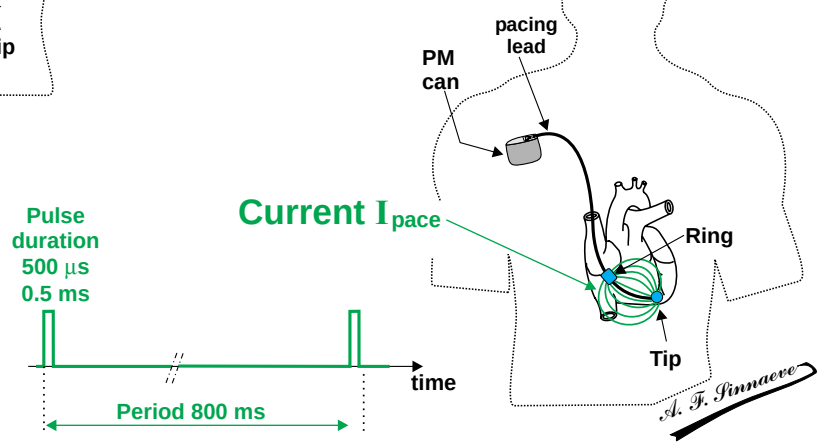
THE SENSOR CIRCUIT

Measuring the transthoracic impedance Z



THE PACING CIRCUIT

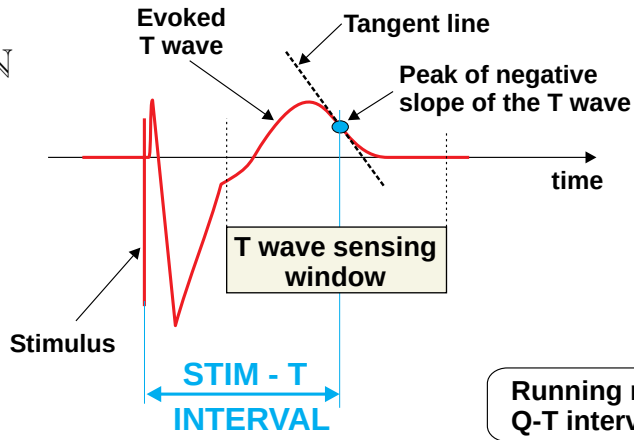
Stimulating the heart



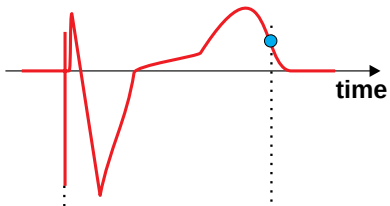
A. F. Sinnaeve

SENSING the QT or STIMULUS - T INTERVAL

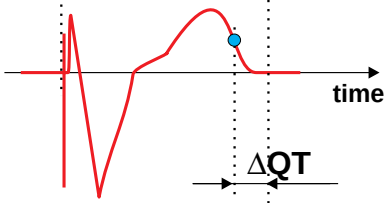
DEFINITION
of
STIMULUS - T INTERVAL
or
EVOKED Q-T INTERVAL

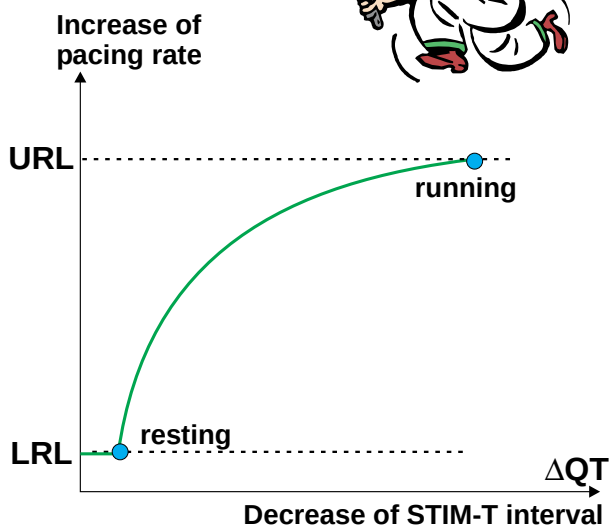


RESTING : LARGER
STIM-T INTERVAL



RUNNING : SHORTER
STIM-T INTERVAL

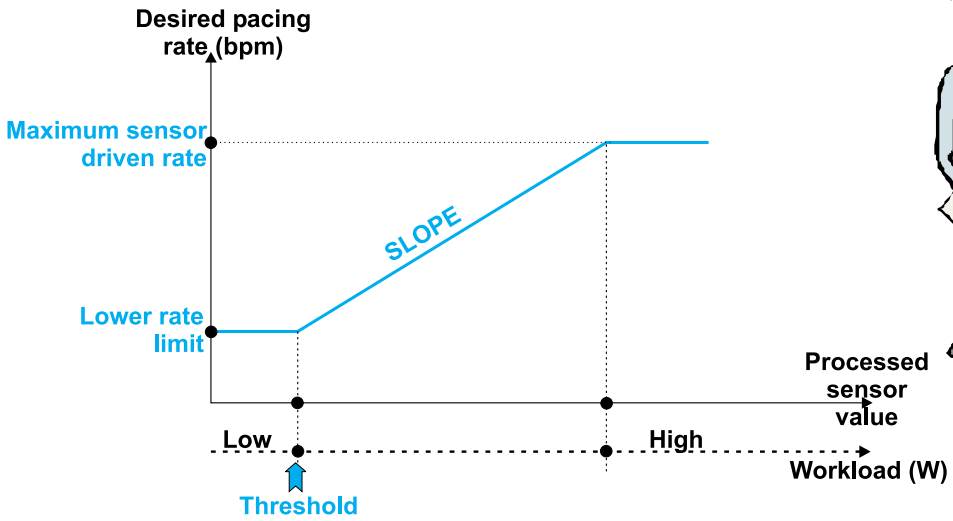




Abbreviations : URL = upper rate limit ; LRL = lower rate limit

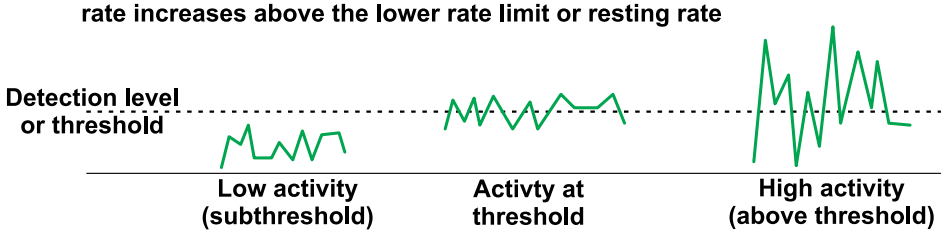
A. F. Sinnaeve

RATE-ADAPTIVE PACING DEFINITIONS

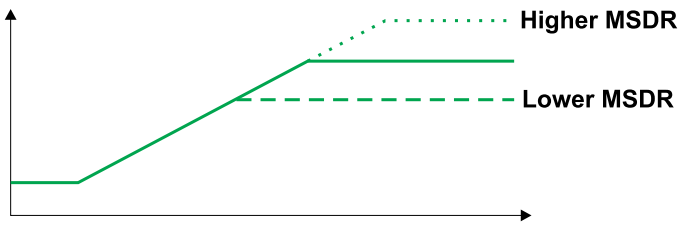


LOWER RATE LIMIT : the minimum desired resting heart rate of the patient (average 65 bpm)

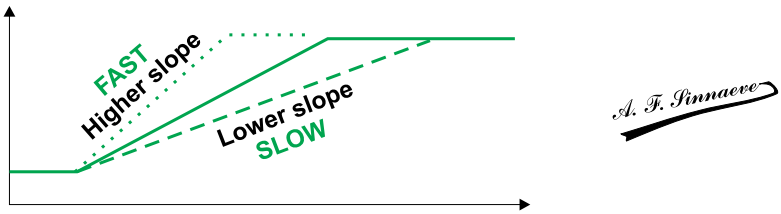
THRESHOLD : minimum workload (or minimum activity) at which the sensor driven pacing rate increases above the lower rate limit or resting rate



MAXIMUM SENSOR DRIVEN RATE : maximum pacing rate induced by the sensor



SLOPE : how fast the sensor driven pacing rate increases in response to the increasing workload (or increasing sensor output signal)



A. F. Sinnaeve

ALGORITHMS FOR RATE-ADAPTIVE PACING

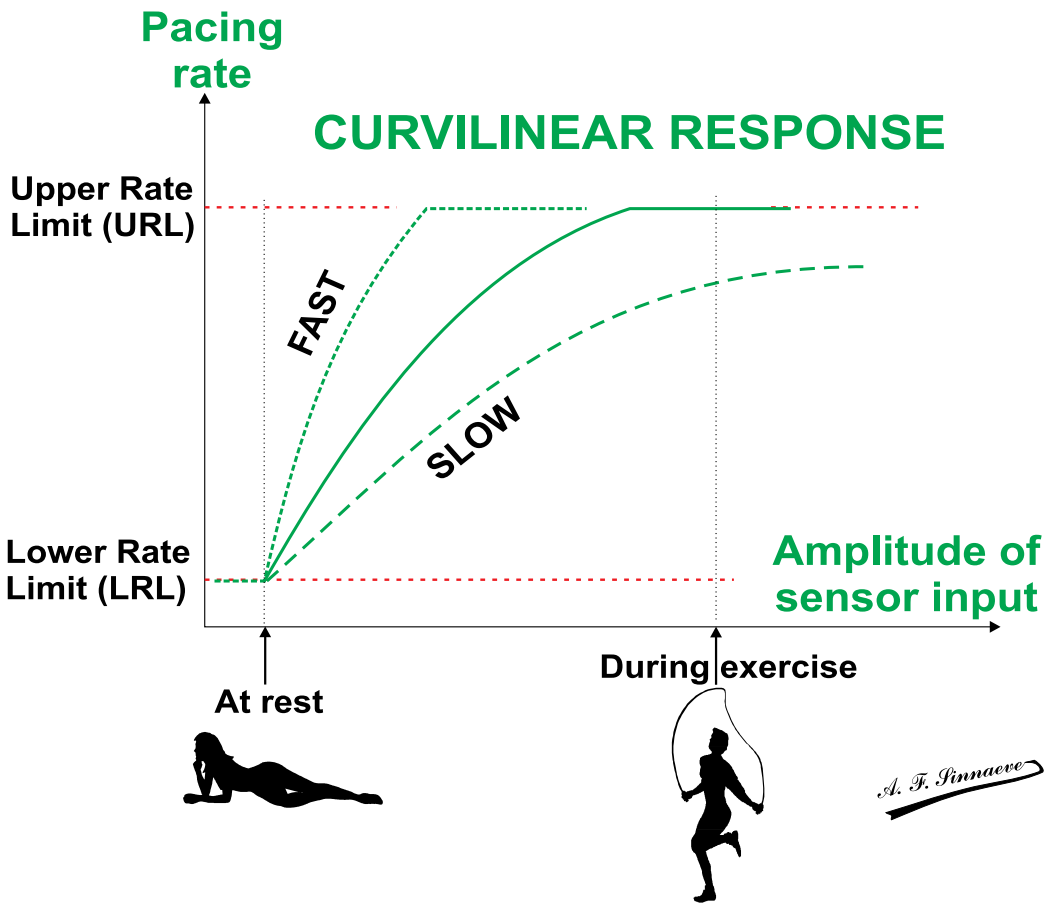
PARAMETERS PROGRAMMED BY THE OPERATOR

THE RANGE OF POSSIBLE PACING RATES

The lower rate limit (LRL) and the upper rate limit (URL) or maximal sensor-driven rate (MSDR) must be programmed

THE RATE RESPONSE SLOPE

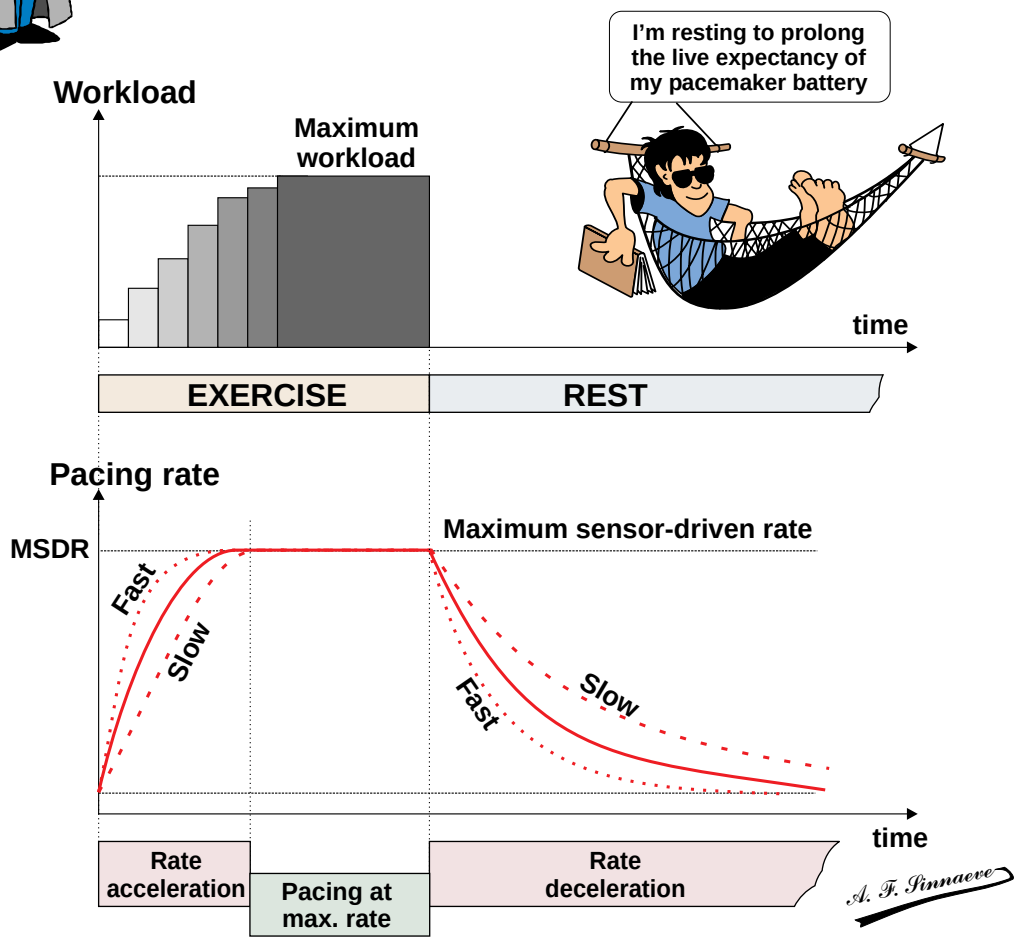
The response of the pacing rate to the signal of the sensor (detected activity, minute ventilation or Q-T time) may be programmed from fast (F) to slow (S) with many different settings



ALGORITHMS FOR RATE-ADAPTIVE PACING

PARAMETERS PROGRAMMED BY THE OPERATOR - PART 2

Many rate adaptive pacemakers use different sets of curves for the post-exercise recovery. The slope of these deceleration curves may be programmed by the operator.

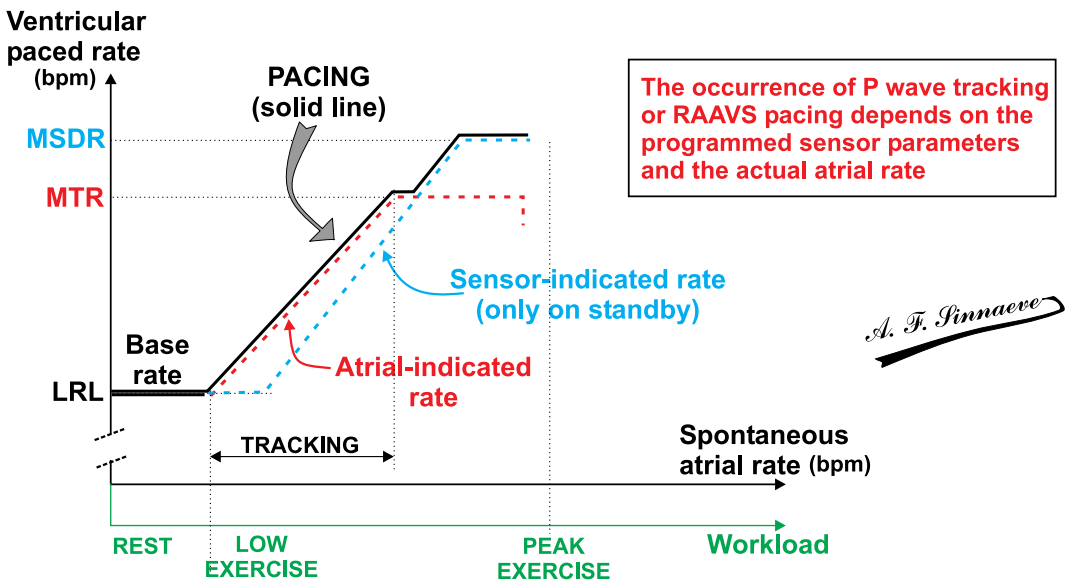


PAY ATTENTION !!! NOTE THE DIFFERENCE BETWEEN ATRIAL-DRIVEN RATE AND SENSOR-DRIVEN RATE

DUE TO INTRINSIC ATRIAL ACTIVITY (e.g. Sinus Node)	DUE TO THE SIGNAL OF THE SENSOR (e.g. Minute Ventilation)
Spontaneous Atrial Interval (SAI)	Sensor-driven Interval (SDI)
Spontaneous Atrial Rate (SAR)	Sensor-driven Rate (SDR)
$\text{SAR (bpm)} = \frac{60\,000}{\text{SAI (ms)}}$	$\text{SDR (bpm)} = \frac{60\,000}{\text{SDI (ms)}}$
Atrial-Driven Upper Rate = Maximum Tracking Rate (MTR)	Sensor-Driven Upper Rate = Maximum Sensor-Driven Rate (MSDR)

Theoretically, there are three possible settings :

* *MSDR > MTR* generally used in patients with atrial chronotropic incompetence
* *MSDR = MTR* useful for rate smoothing to prevent sudden pauses at high atrial rates
* *MSDR < MTR* limited usefulness e. g. when the sinus rate may suddenly drop during exercise (sick sinus syndrome) and in certain patients with activity sensors who are obligatorily exposed to vibrations (Parkinson's disease, truck drivers, etc.)



The occurrence of P wave tracking or RAAVS pacing depends on the programmed sensor parameters and the actual atrial rate

A. F. Sinnaeve

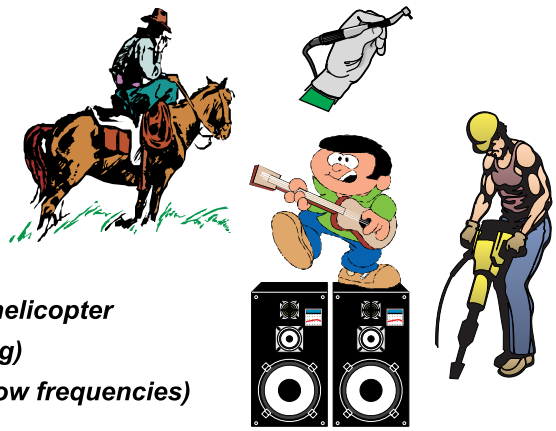
Abbreviations : LRL = lower rate limit; MSDR = maximum sensor-driven rate; MTR = maximum tracking rate; RAAVS = rate-adaptive AV sequential pacing; SAI = spontaneous atrial interval; SAR = spontaneous atrial rate; SDI = sensor-driven interval; SDR = sensor-driven rate.

UNWANTED RESPONSES OF SENSORS - PART 1

1 SENSORS OF BODY MOTION

The pacing rate of devices with an activity sensor or an accelerometer depends on the type of activity and does not correlate well with the level of exertion or the amount of work, i.e. body vibration is not proportional to the level of energy expenditure

1/ Environmental interference may cause an unwanted increase in pacing rate (less pronounced for devices equipped with an accelerometer) :

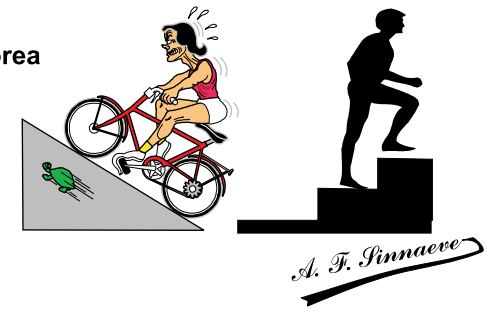


- ***riding on horseback***
- ***driving in a car on rough terrain***
- ***riding on a motorcycle on a bad road***
- ***flying in a small-engine aircraft or in a helicopter***
- ***the use of drills (including dental drilling)***
- ***very loud rock music (especially ultra-low frequencies)***

2/ Postoperative shivering and anxiety-provoked shivering may cause a persistent pacemaker tachycardia

3/ Epileptic seizures and myotonic jerking with chorea can increase the pacing rate

4/ When bicycling the condition of the road influences the rate response excessively, while walking downstairs may cause a larger rate increase than walking upstairs

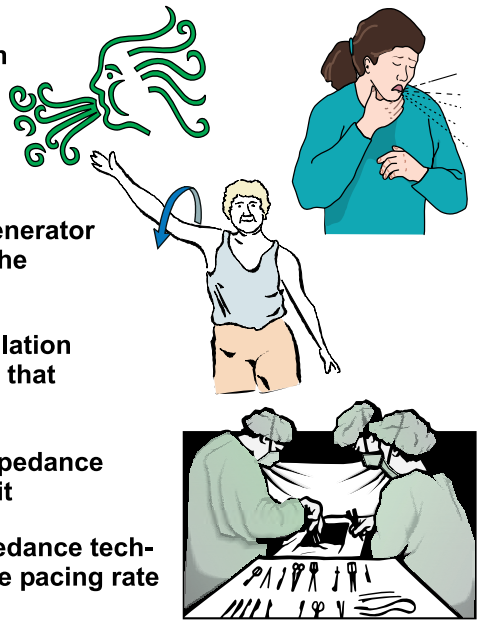


A. P. Sinnaeve

UNWANTED RESPONSES OF SENSORS - PART 2

2 SENSORS OF MINUTE VENTILATION

Systems with a minute ventilation sensor are highly physiologic and therefore highly specific. Occasionally the reaction to the onset of exercise may be delayed and the rate may be too fast after the end of exercise



1/ Hyperventilation, coughing and tachypnea from chest infection or congestive heart failure can increase the pacing rate
(contraindicated in patients with chronic obstructive pulmonary disease)

2/ Swinging of the arm on the side of the pulse generator and rotating shoulder movements may increase the pacing rate

3/ During general anesthesia, an increase in ventilation can produce a substantial increase in pacing rate that may cause hypotension

4/ Electrocautery may provoke changes of the impedance and thus increase the pacing rate to its upper limit

5/ Some systems in the CCU that use similar impedance technology to monitor respiration, can also disturb the pacing rate

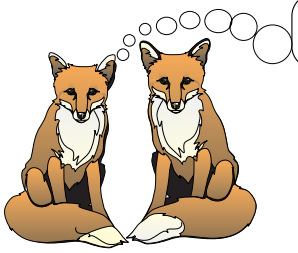
3 Q-T SENSOR

The Stim-T interval not only responds to exercise, but also to emotion. However, the QT interval reacts rather slowly.

1/ T wave detection may be hampered by frequent ventricular ectopy, by ventricular fusion beats and by substantial lead polarization

2/ The Q-T interval may be affected by electrolyte disturbances, some medications and coronary artery disease with myocardial ischemia or infarction

A. F. Sinnaeve

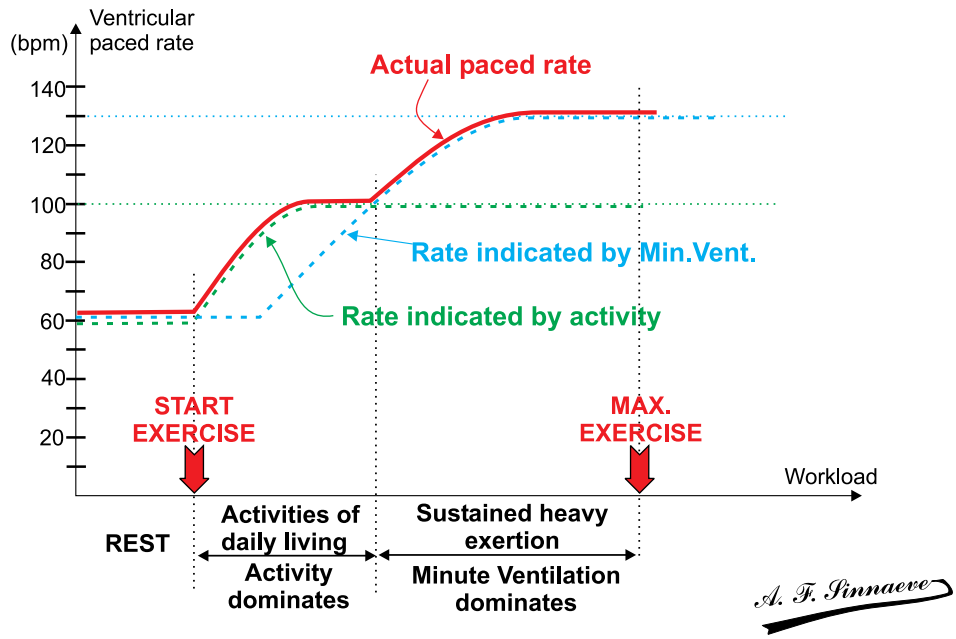


DUAL SENSORS & SENSOR BLENDING PART 1

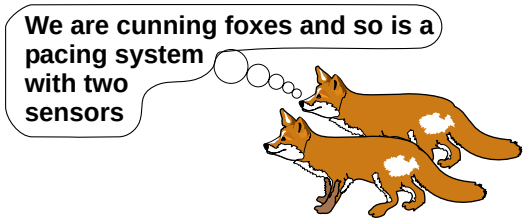
A combination of two sensors is used to improve the correlation to workload for various forms of exercise and to minimize paradoxical responses

NON-PHYSIOLOGIC OR MECHANICAL INDICATORS	PHYSIOLOGIC OR METABOLIC INDICATORS
SENSORS : Activity sensors Accelerometers	*SENSORS* : Minute Ventilation QT- interval
PRO : fast responding	*CONTRA* : slow responding
CONTRA : low specificity i.e. Increased incidence of false positive responses unrelated to actual exercise	*PRO* : high specificity i.e. Lesser incidence of false positive responses unrelated to actual exercise

The combination of a physiologic and a non-physiologic sensor results in a rate response that mimics normal sinus node response closely and that to a great extent ignores false positive sensor information

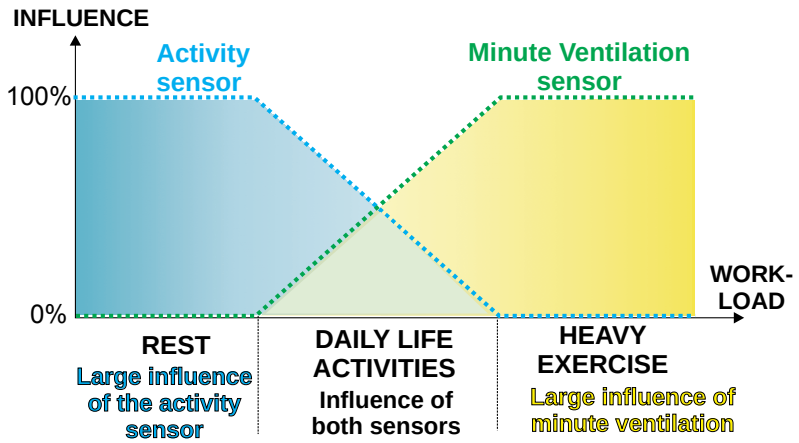


DUAL SENSOR PACING PART 2



SENSOR BLENDING determines the relative influence of each sensor upon the pacing rate.

Depending upon the sophistication of the algorithm, the blending may be programmed in fixed steps (0/100 - 30/70 - 50/50 - 70/30 - 100/0) or the relative contribution of each sensor may vary automatically across the rate response range



SENSOR CROSS-CHECKING reduces false responses

ONE — The activity sensor indicates a higher rate, while the minute ventilation sensor indicates a constant low rate (e.g. nonphysiologic vibrations) : only a limited increase of stimulation rate will occur during a short period of time

TWO — The activity sensor denotes a constant low rate while the minute ventilation sensor is asking for a higher rate (e.g. due to fever or to hyperventilation) : the simulation rate will only slightly increase

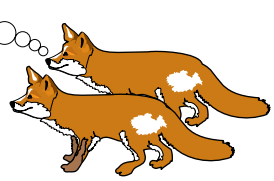
THREE — Both the activity sensor and the minute ventilation sensor are indicating a higher rate : the stimulation rate will augment in the correct way

FOUR — Both the activity sensor and the minute ventilation sensor are pointing towards a lower rate : the stimulation rate will decrease appropriately

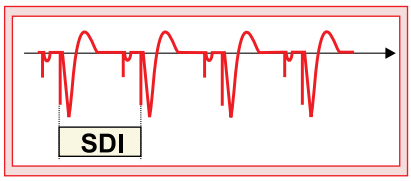
A. F. Sinnaeve

DUAL SENSOR PACING
PART 3 : SENSOR CROSS-CHECKING

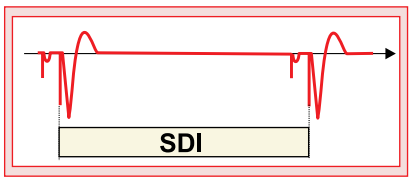
We are cunning foxes and so is a pacing system with two sensors



I had a pacemaker with an activity sensor. Every time I drove on this bumpy road, my heart rate went up a lot … !!!



Now I have a pacemaker with two sensors, activity and QT.
Even driving faster on the same bumpy road, my heart rate goes up only slightly!!!

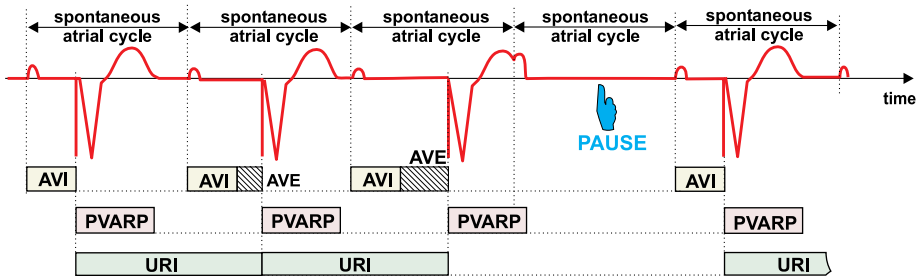


A. F. Sinnaeve

Abbreviations : SDI = sensor driven interval

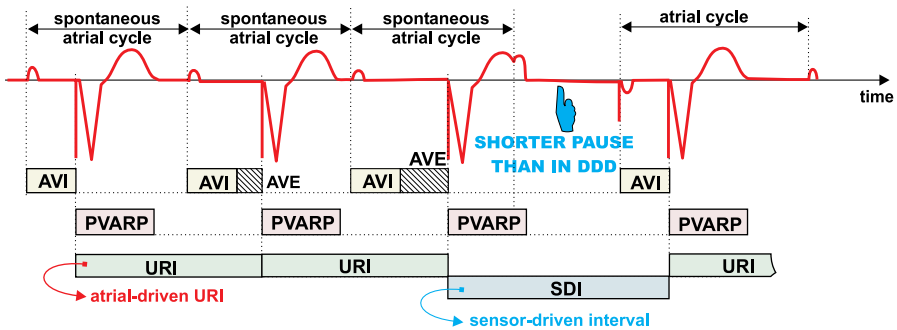
WENCKEBACH UPPER RATE BEHAVIOR DURING RATE - ADAPTIVE PACING

1. DDD pacing (ventricular-based timing)

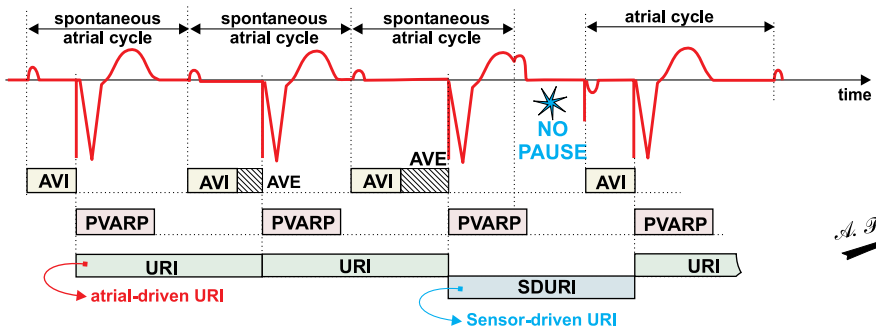


2. Sensor-driven rate smoothing (DDDR ventricular-based timing)

When the sensor-driven interval is longer than the atrial-driven upper rate interval



When the sensor-driven interval (equal to the sensor-driven upper rate interval SDURI) is equal to the atrial-driven upper rate interval

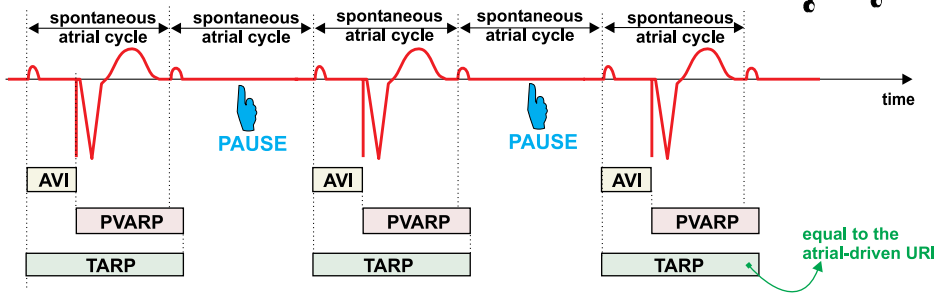


A. F. Pinnaeve

Abbreviations : AVI = programmed AV delay ; AVE = AV extension ; PVARP = postventricular atrial refractory period ; URI = atrial-driven upper rate interval ; SDI = sensor driven interval ; SDURI = sensor-driven upper rate interval

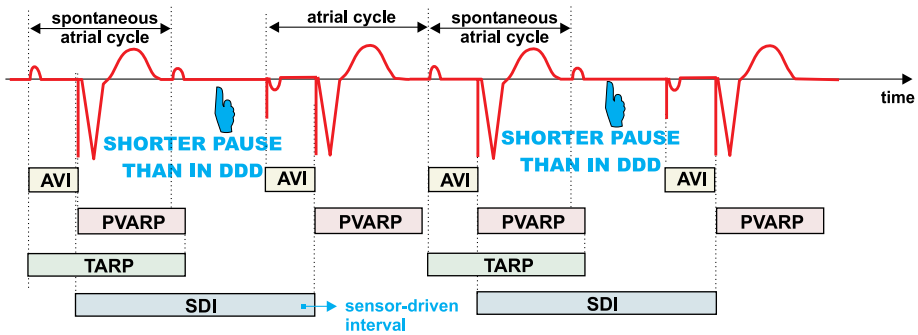
2 :1 BLOCK UPPER RATE BEHAVIOR DURING RATE - ADAPTIVE PACING

1. DDD pacing (ventricular-based timing)

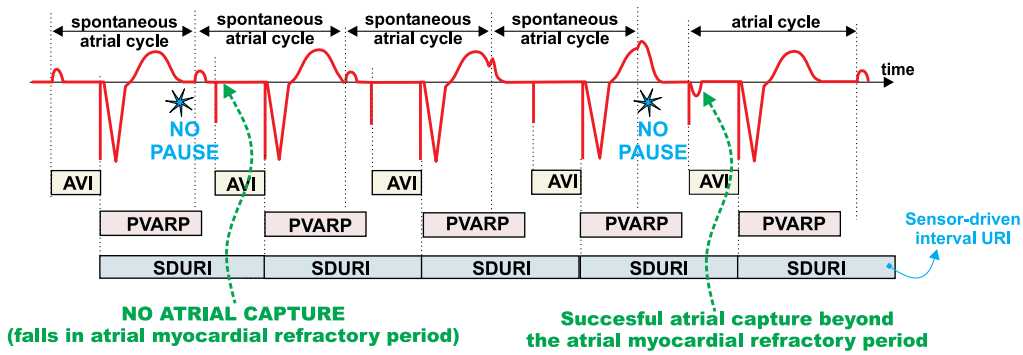


2. Sensor-driven rate-smoothing (DDDR ventricular-based timing)

When the sensor-driven interval is longer than the atrial-driven upper rate interval



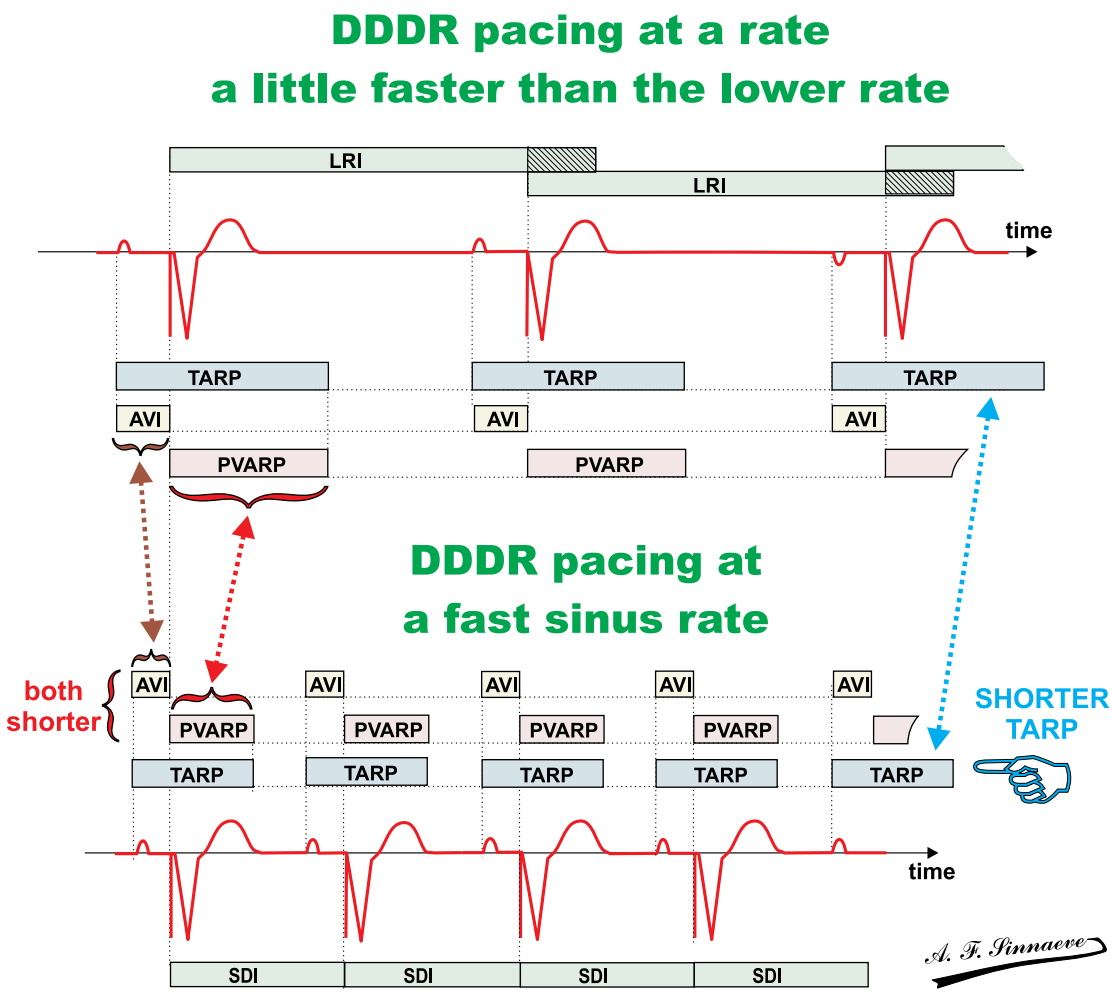
When the sensor-driven interval (equal to the sensor-driven upper rate interval SDURI) is equal to the atrial-driven upper rate interval



Abbreviations : AVI = programmed AV delay ; AVE = AV extension ; PVARP = postventricular atrial refractory period ; URI = atrial-driven upper rate interval ; SDI = sensor driven interval ; SDURI = sensor-driven upper rate interval ; TARP = total atrial refractory interval

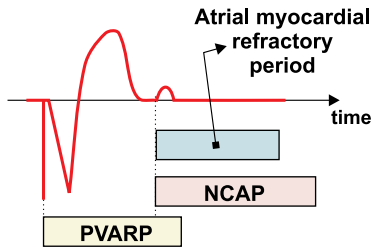
RATE-ADAPTIVE PVARP

- At low rates, the PVARP is longer. A long PVARP enhances protection against sensing of retrograde P waves and induction of endless loop tachycardia.
- At high sensor-indicated rates, PVARP shortening (in conjunction with a shorter rate adaptive sAVI) shortens the TARP thus providing for a higher 2:1 block rate and tracking faster atrial rates on a 1:1 basis than otherwise possible

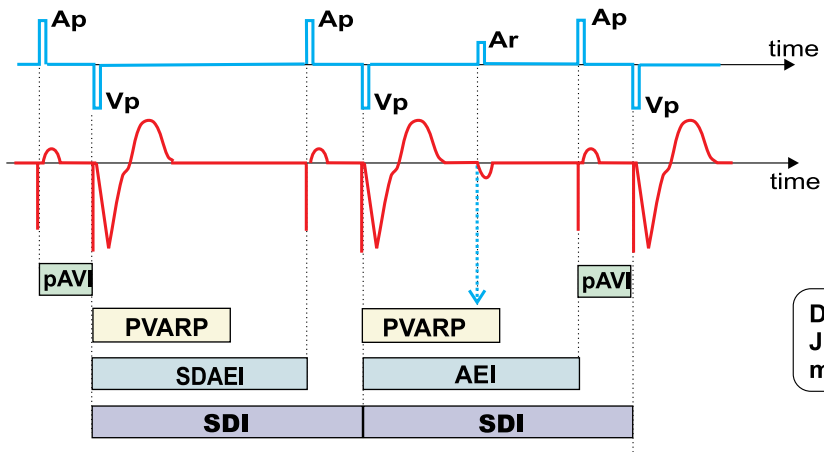


Abbreviations : AVI = programmed AV delay; PVARP = postventricular atrial refractory period; SDI = sensor-driven interval; LRI = lower rate interval; TARP = total atrial refractory period

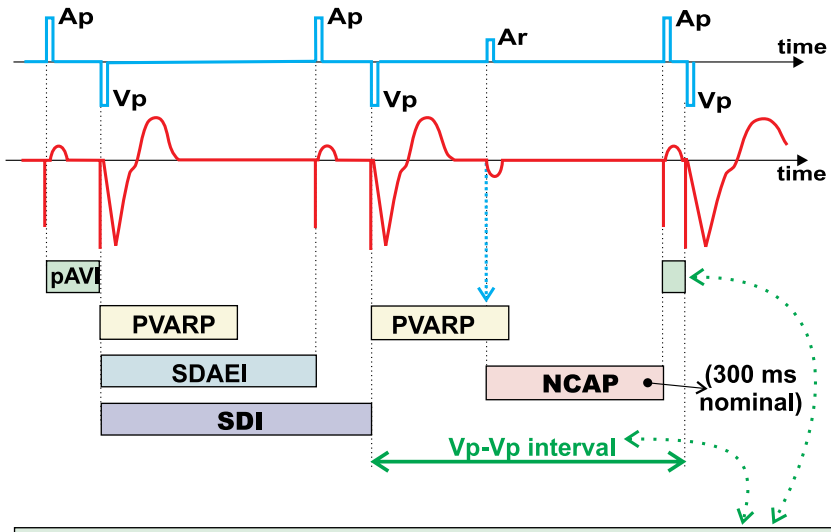
NON-COMPETITIVE ATRIAL PACING (NCAP)



The NCAP interval is a period of time when the pacemaker is prevented from delivering an atrial stimulus. This function was designed to prevent the induction of atrial tachyarrhythmias by an atrial pacing stimulus falling into the atrial relative refractory period and the vulnerable period of the atrium.



WITHOUT NCAP

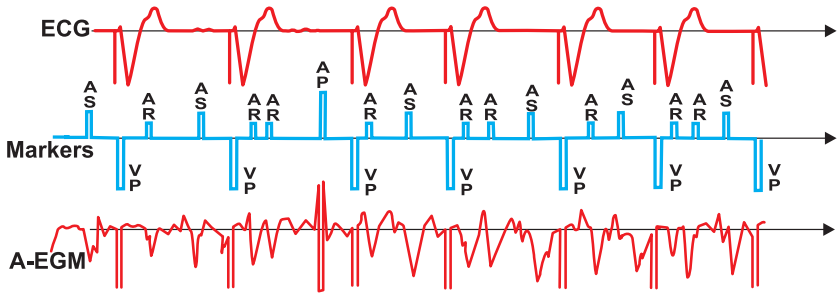


WITH NCAP

The pacemaker tries to maintain the sensor-driven ventricular cycle at the expense of the AV delay which may shorten for this adaption

A. F. Sinnaeve

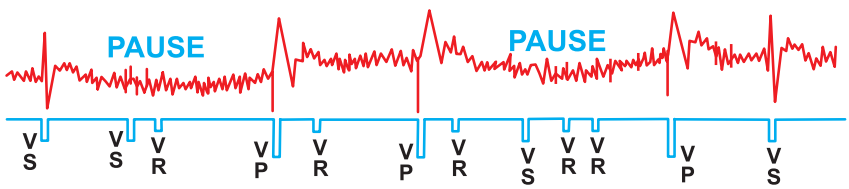
Abbreviations : Ap = atrial paced event; Ar = atrial refractory sensed event; Vp = ventricular paced event; pAVI = paced atrioventricular interval; PVARP = postventricular atrial refractory period; SDAEI = sensor driven atrial escape interval; SDI = sensor driven interval; NCAP = non-competitive atrial pacing period.



PACEMAKER TACHYCARDIAS - PART 1

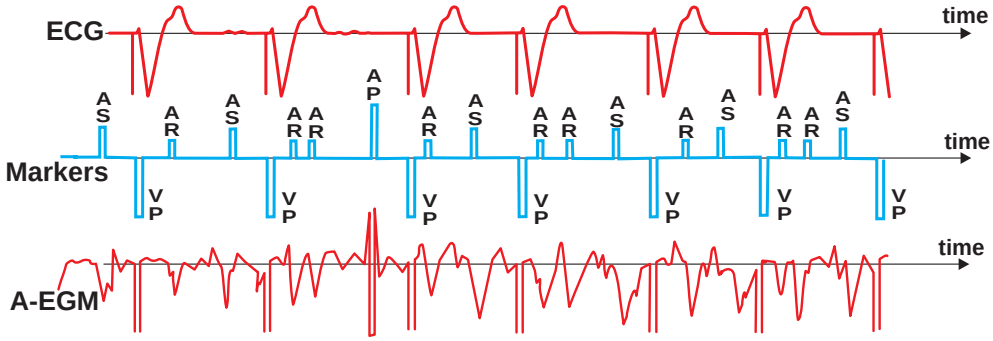
* Atrial fibrillation - part 1
* Atrial fibrillation - part 2
* Myopotential oversensing - part 1
* Myopotential oversensing - part 2
* Maneuvers to demonstrate myopotentials

A. F. Sinnaeve



DDD PACEMAKERS AND ATRIAL FIBRILLATION - Part 1

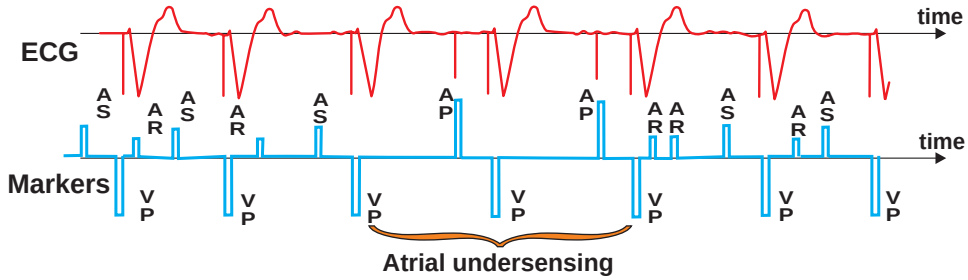
1 A FIB may provoke a fast ventricular response (regular or irregular)



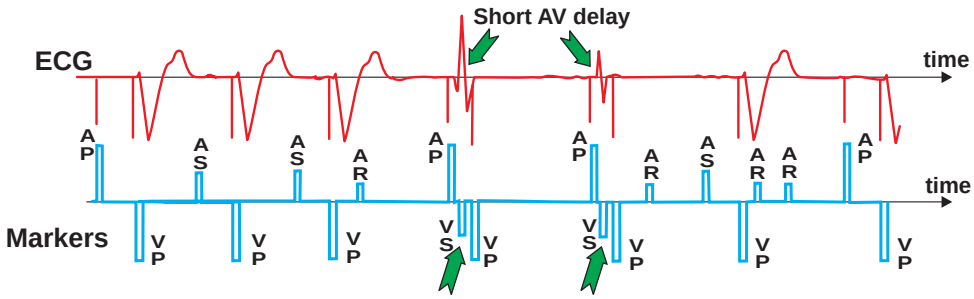
CAUTION
ELIMINATE DOUBT...LOCK IT OUT

A fast and irregular pacemaker tachycardia is almost always due to atrial fibrillation !!!

2 Intermittent sensing of f waves ; mixed response



3 Ventricular safety pacing when f waves are unsensed (VSP occurs with a spontaneous QRS complex or an EMI signal that comes after AP but before the expected VP)

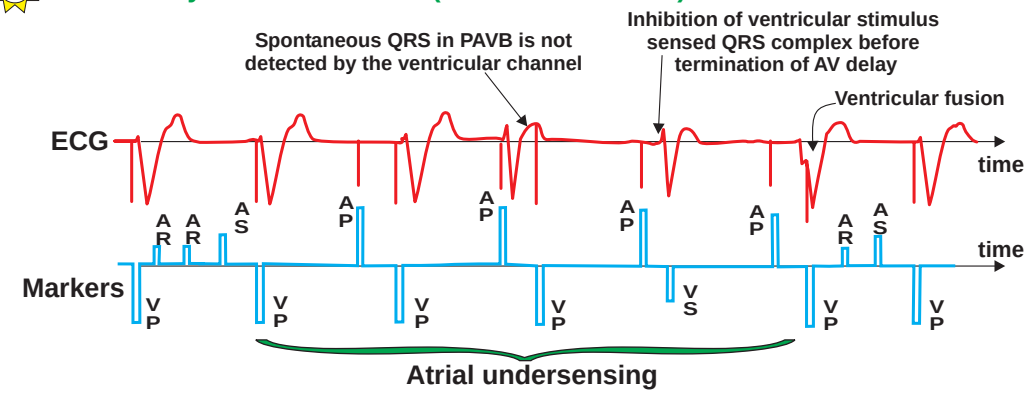


Abbreviations : AS = sensed atrial event; AR = atrial sense in refractory period; AP = atrial pace; VP = ventricular pace; VS = ventricular sense; SDI = sensor-driven interval; A FIB = atrial fibrillation; AMS = automatic mode switching; PAVB = postatrial ventricular blanking; VSP = ventricular safety pacing; EMI = electromagnetic interference

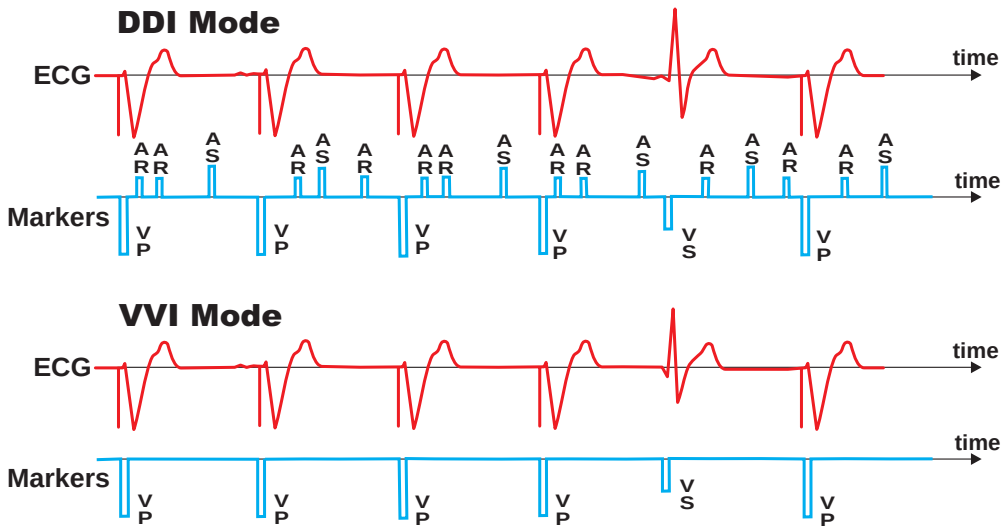
A. F. Pinnaeve

DDD PACEMAKERS AND ATRIAL FIBRILLATION - Part 2

4 A FIB may create confusion (VSP switched OFF)



5 A FIB and Automatic Mode Switching (AMS)

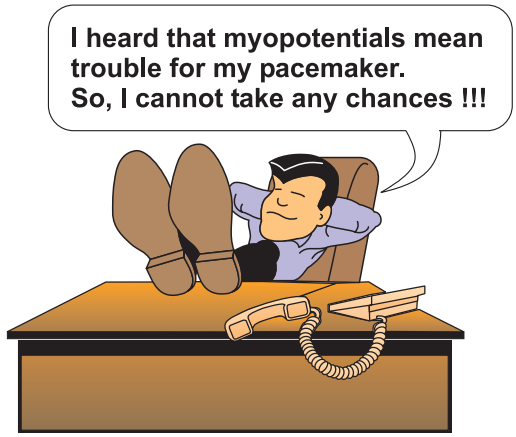


* **AMS protects the patient from tracking rapid atrial rates by switching to a non-atrial tracking mode**
* **According to programmability, AMS can switch from DDD or DDD(R) to VVI, VVI(R), DDI or DDI(R)**
* **The DDI mode is functionally identical to the VVI mode**

Abbreviations : AS = sensed atrial event; AR = atrial sense in refractory period; AP = atrial pace; VP = ventricular pace; VS = ventricular sense; SDI = sensor-driven interval; A FIB = atrial fibrillation; AMS = automatic mode switching; PAVB = postatrial ventricular blanking; VSP = ventricular safety pacing

A. F. Sinnaeve

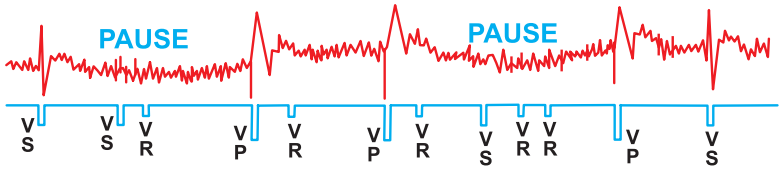
MYOPOTENTIAL SENSING DURING UNIPOLAR DDD PACING - Part 1



Baseline interference of the surface ECG is characteristic of myopotential oversensing

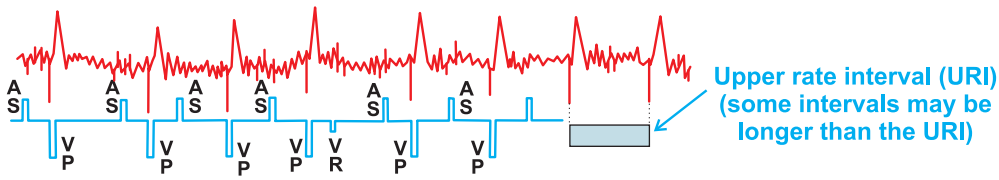
1 INHIBITION OF THE VENTRICULAR CHANNEL

(VVI Mode)

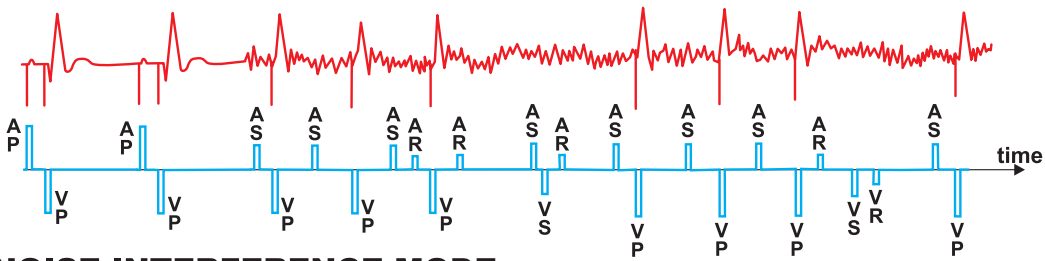


2 TRIGGERING OF RAPID VENTRICULAR RATES

Sensing by the atrial channel with resultant triggering of ventricular pacing and increase in the paced ventricular rate : tachycardia which can cause symptoms of uncomfortable palpitations, angina, dyspnea, etc.

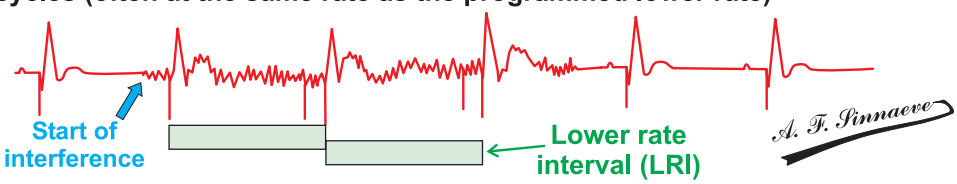


3 MIXED RESPONSE WITH INHIBITION & TRIGGERING



4 NOISE INTERFERENCE MODE

Reversion to the asynchronous noise interference mode is possible for 1 or more cycles (often at the same rate as the programmed lower rate)

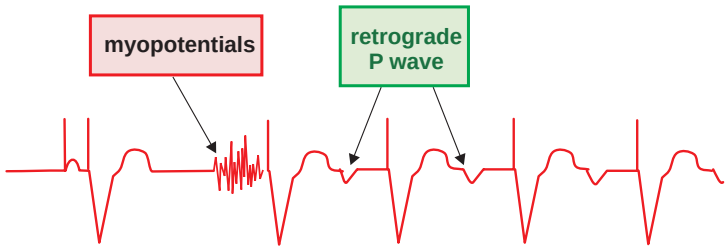


Abbreviations : AP = atrial pace; AS = atrial sense; AR = atrial sense in refractory period; VP = ventricular pace; VS = ventricular sense; VR = ventricular sense in refractory period; URI = upper rate interval

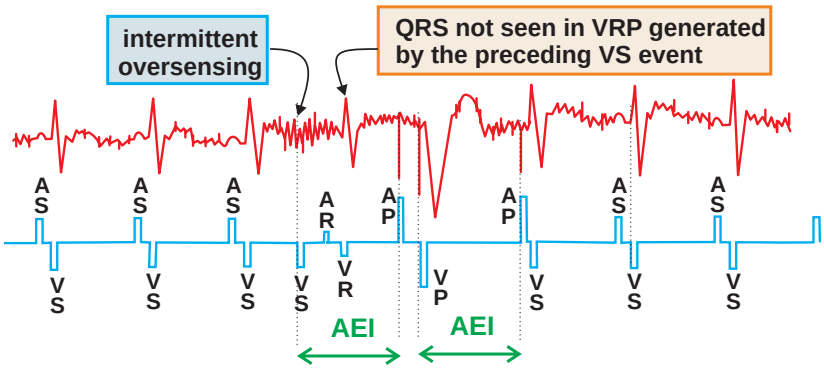
MYOPOTENTIAL SENSING DURING DDD PACING
Part 2

5 PRECIPITATION OF ELT

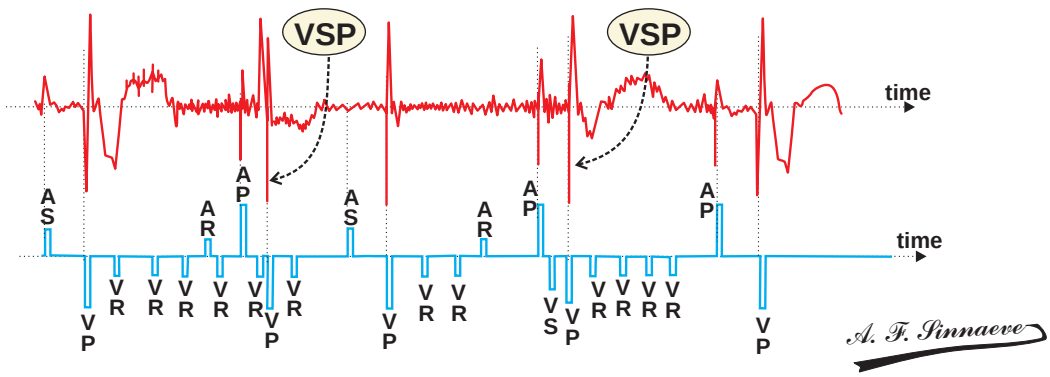
Myopotential sensing by the atrial channel can precipitate an endless loop tachycardia



6 UNDERSENSING SECONDARY TO OVERSENSING



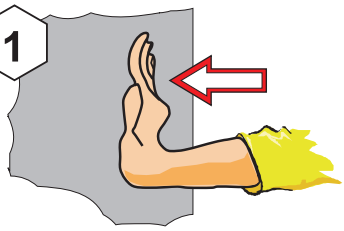
7 MIXED RESPONSE WITH VENTRICULAR SAFETY PACING



Abbreviations : AP = atrial pace; AS = atrial sense; AR = atrial sense in refractory period; VP = ventricular pace; VS = ventricular sense; VR = ventricular sense in refractory period; URI = upper rate interval; VSP = ventricular safety pacing; AEI = atrial escape interval; VRP = ventricular refractory period; ELT = endless loop tachycardia

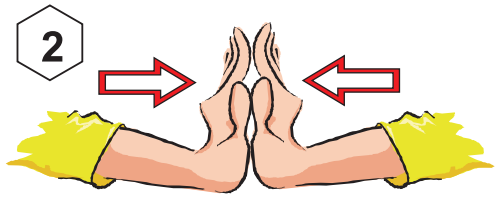
COMMONLY USED MANEUVERS TO DEMONSTRATE MYOPOTENTIALS

1



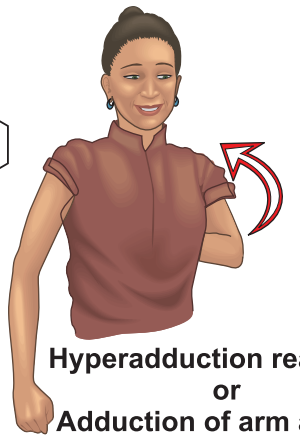
Pressing against a wall

2



Pressing hands against each other

3

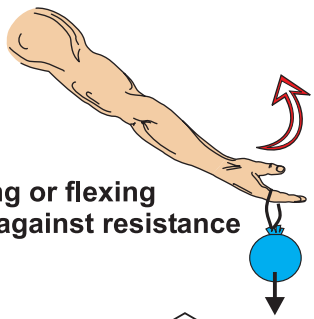


Hyperadduction reach test
or
Adduction of arm against resistance

4

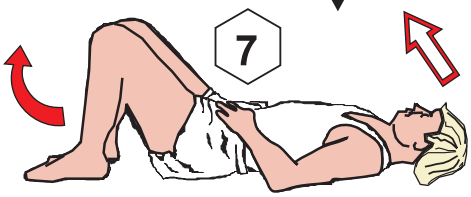
Cup the hand over the shoulder and exert firm and sustained downward pressure

5



Lifting or flexing arm against resistance

7

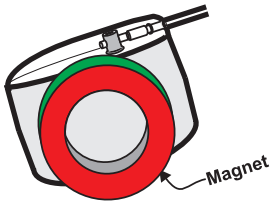


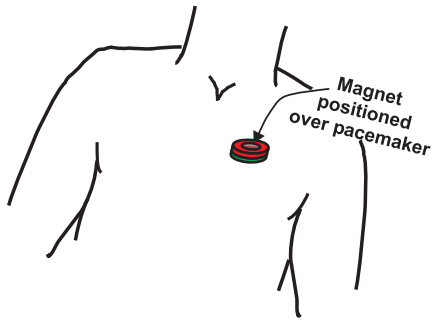
Trunk lifting or
Lifting & holding legs

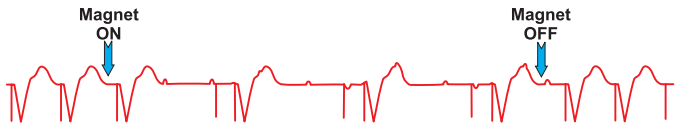
6

Treadmill stress test

A. F. Sinnaeve

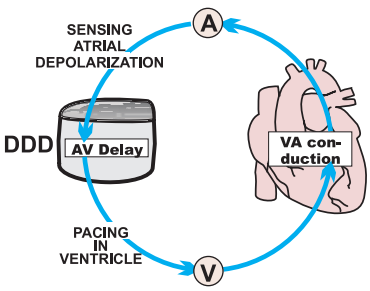


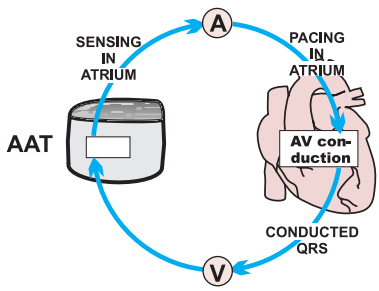




PACEMAKER TACHYCARDIAS - PART 2

* Differential diagnosis of tachycardia - part 1
* Differential diagnosis of tachycardia - part 2
* Orthodromic tachycardia



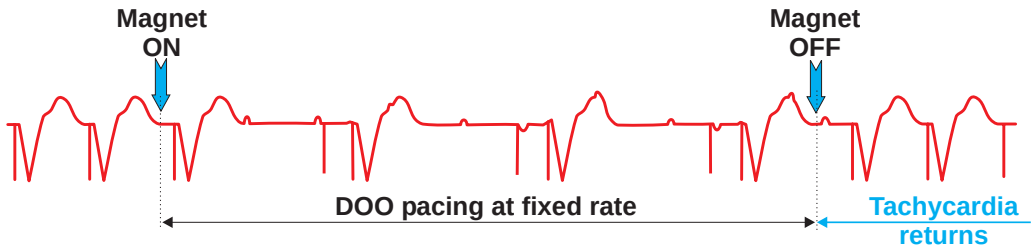


A. F. Sinnaeve

DIFFERENTIAL DIAGNOSIS OF TACHYCARDIA DURING DDD(R) PACING part 1

1 SINUS TACHYCARDIA

* Application of the magnet (slower DOO mode) may reveal P waves. The tachycardia returns upon withdrawal of the magnet.



* Atrial electrogram and markers will also reveal a regular atrial rate
* Pacemaker Wenckebach upper rate response suggests a regular rate faster than the programmed upper rate. In this case it could also be an atrial tachycardia ! A Wenckebach upper rate response effectively rules out endless loop tachycardia.

2 ATRIAL FLUTTER & FIBRILLATION

* The paced ventricular rate is fast and may be regular or irregular
* Diagnosis is suggested when the ventricular pacing rate is fast and irregular and may be confirmed by recording the telemetered atrial electrogram

3 MYOPOTENTIAL TRIGGERING

* A pacemaker tachycardia can be triggered by myopotentials sensed by the atrial channel of pacemakers with unipolar sensing
* The tachycardia may be regular or irregular, with pacing cycles often at the upper rate interval. The tachycardia is mostly short-lived and pacing quickly returns to baseline
* Diagnosis : the tachycardia is reproducible by standard maneuvers to bring out myopotentials. A decrease in atrial sensitivity followed by a repeat of the maneuvers often shows elimination of the tachycardia.

A. F. Sinnaeve

Abbreviations : EMI = electromagnetic interference; DOO = asynchronous dual chamber pacemaker

DIFFERENTIAL DIAGNOSIS OF TACHYCARDIA DURING DDD(R) PACING - part 2

4 ENDLESS LOOP TACHYCARDIA

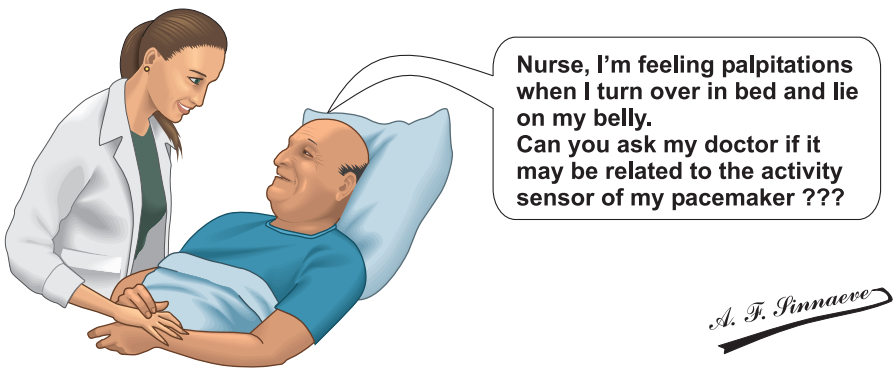
* The telemetered markers show a constant VA (Vs-As) interval
* Disappears upon application of the magnet and with programming a longer PVARP
* There are two types : near-field and far-field (rare)

5 ORTHODROMIC PACEMAKER TACHYCARDIA

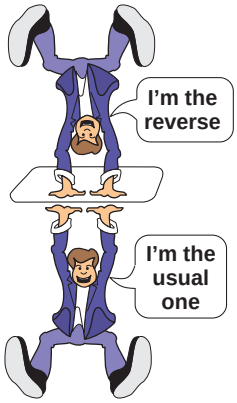
* The opposite of ELT in that there is atrial pacing associated with conducted QRS complexes (rare)

6 SENSOR RELATED TACHYCARDIAS

* Inappropriate overprogramming of the sensor response with exessive response to effort
* Minute ventilation sensor in patients with CHF and in patients undergoing electro-cautery during a surgical intervention
* ECG monitors, etc. using the same high frequency low amplitude signals as the minute ventilation sensor of the pacemaker, may cause pacing at upper rate
* Excessive shivering or post-epileptic state of patients with activity sensors
* Firm pressure over an activity-driven pacemaker



Abbreviations : ELT = endless-loop tachycardia; CHF = congestive heart faillure; DOO = asynchrone dual chamber pacemaker.



ORTHODROMIC MACRO-REENTRANT PACEMAKER TACHYCARDIA

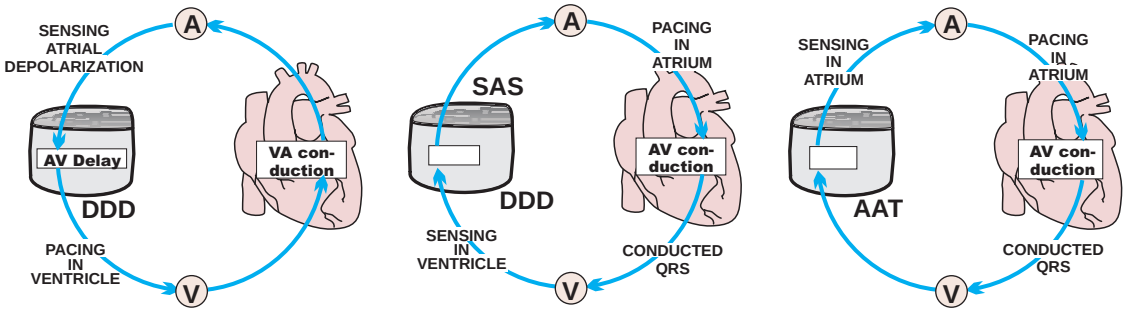
Orthodromic pacemaker tachycardia has been called "reverse endless loop tachycardia". There is anterograde conduction across the AV junction and the QRS is conducted and not paced. This is the opposite of ELT where there is ventricular pacing. The return pathway is via the pacemaker by producing atrial pacing in contrast to ELT where there is atrial sensing !

Endless loop tachycardia or ELT

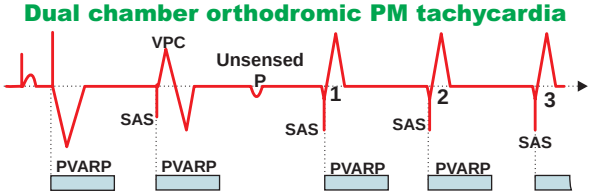
Orthodromic macro-reentrant pacemaker tachycardia

Near-field dual chamber

Far-field single chamber

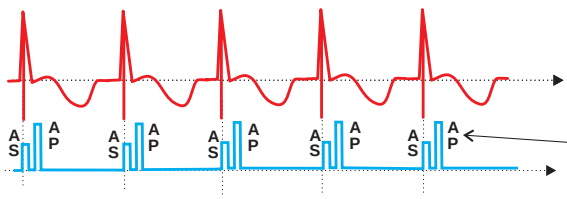


Dual chamber orthodromic PM tachycardia



Mechanism of orthodromic pacemaker tachycardia during DDD pacing with synchronous atrial stimulation (SAS) algorithm to prevent ELT. SAS delivers an atrial stimulus on detection of a VPC. In this way, retrograde VA conduction engendered by a VPC cannot cause atrial depolarization because it is pre-empted by SAS that renders the atrium refractory. A VPC is sensed by the ventricular electrode, thereby triggering SAS. This is followed by an unsensed P wave outside the PVARP. The unsensed P wave is conducted and gives rise to the first conducted QRS complex that is sensed beyond the ventricular refractory period of the PM. The pulse generator interprets this conducted QRS complex as a VPC and delivers SAS. This again leads to a conducted QRS complex (2) with a very long PR interval. The second QRS complex causes SAS 2, and SAS 2 causes QRS 3, etc...

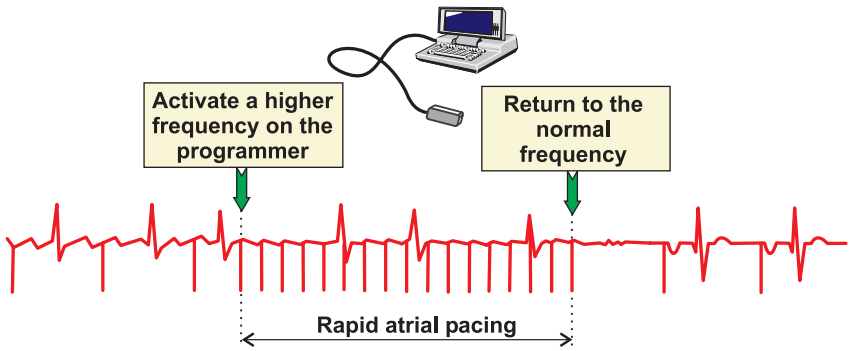
AAT single chamber orthodromic PM tachycardia



Far-field sensing of the R wave triggers an atrial stimulus which captures the atrium. The P wave is conducted to the ventricle. The conducted QRS is again sensed by the atrial lead as a far-field signal and the process perpetuates itself.

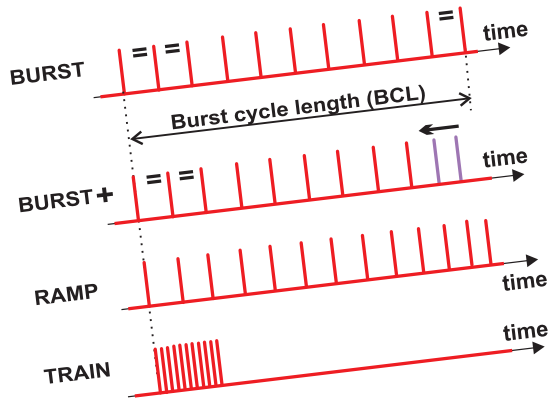
A. F. Sinnaeve

Abbreviations : AAT = an atrial stimulus is promptly delivered upon sensing in the atrium; ELT = endless-loop tachycardia; SAS = synchronous atrial stimulation; PVARP = postventricular atrial refractory period; VPC = ventricular premature coplex; AS = atrial sensed event; AP = atrial pacing; PM = pacemaker



TREATMENT OF TACHYCARDIA

* Antitachycardia pacing (ATP) - part 1
* Antitachycardia pacing (ATP) - part 2
* Prevention of atrial fibrillation

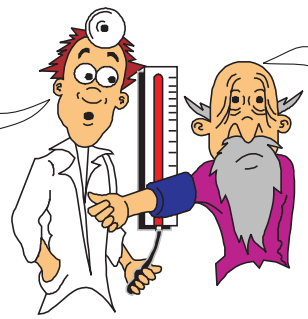


A. F. Sinnaeve

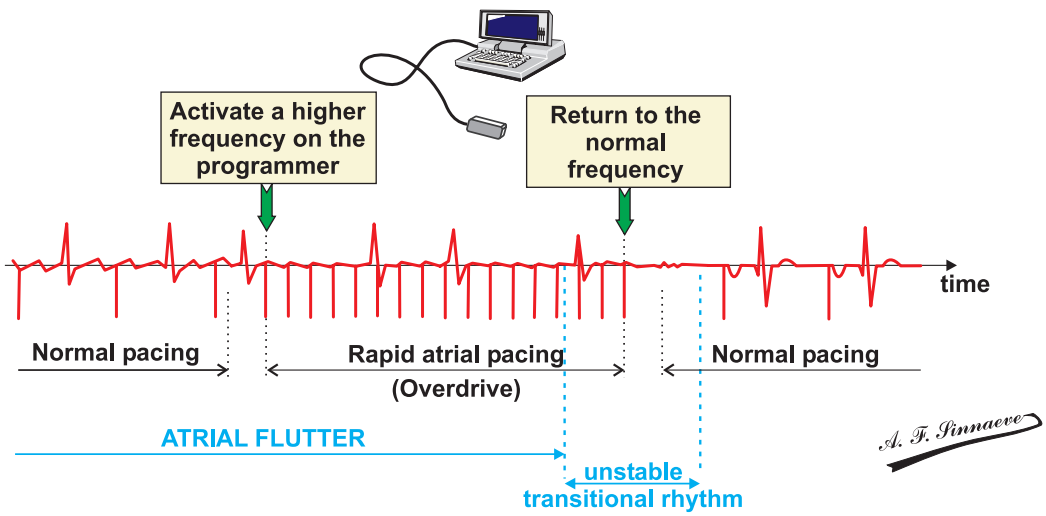
TREATMENT OF TACHYCARDIA WITH PACING PART 1

Manual procedure with the programmer : Overdrive pacing

Overdrive pacing at a fast rate is easy to perform.
Put the head of the programmer over the pacemaker and temporarily program a pacing rate faster than the heart rate. Upon termination of the tachycardia, return to the normal pacing rate.



I don't trust those machines !
My physician has to do it himself !!!



CAUTION

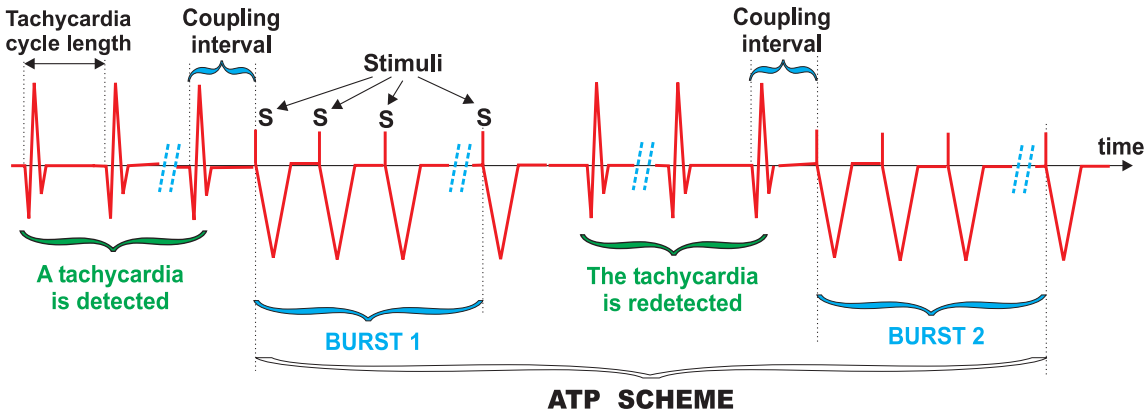
The procedure requires a standby defibrillator in the rare case of a complication

Rapid overdrive pacing is important for the treatment of reentrant supraventricular tachyarhythmias such as atrial flutter and other organized atrial tachycardias. It is ineffectual for atrial fibrillation.

TREATMENT OF TACHYCARDIA WITH PACING PART 2

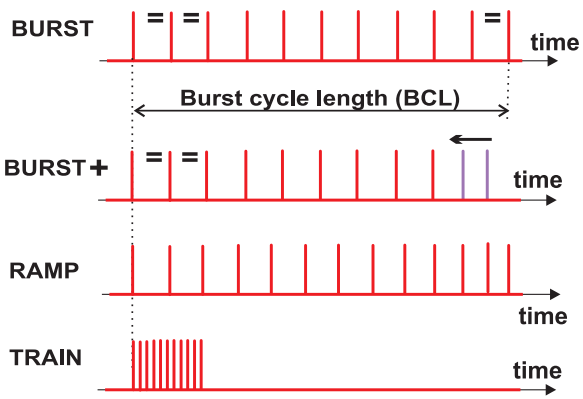
Automatic : Antitachycardia Pacing (ATP)

This function is available in pacemakers for atrial pacing in the treatment of supraventricular tachyarrhythmias. Only defibrillators (ICDs) can deliver rapid ventricular pacing for ventricular tachycardia because the procedure may occasionally accelerate the tachycardia or precipitate ventricular fibrillation, arrhythmias that require immediate defibrillation !!!



ATP SCHEME

Some basic stimulation patterns



All pacing intervals within the burst are the same

A burst followed by 2 stimuli with a decremental coupling interval

The pacing intervals within the burst are continuously decreased (or increased in some pacemakers)

A high frequency burst pacing at 50Hz (3000bpm) during 0.5 - 3 seconds

WHAT CAN BE PROGRAMMED ?

* The number of bursts delivered
* The number of pulses within each burst
* The coupling interval as a % of the tachycardia cycle length
* The burst cycle length
* A minimum pacing interval

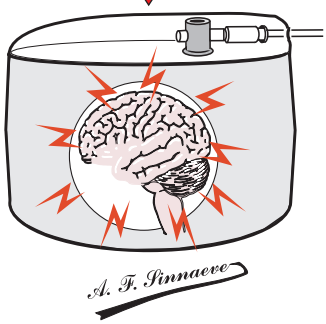
Many combinations are possible and different terminology is used by different manufacturers !

A. F. Sinnaeve

THE PREVENTION OF ATRIAL FIBRILLATION

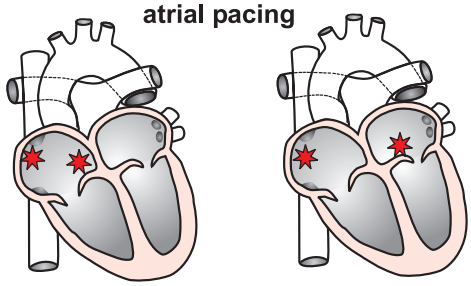
- **Continuous overdrive of sinus rate at a dynamic rate**. This ensures atrial pacing without an excessive increase in the rate.
- **Prevention of post-extrasystolic pauses**. This prevents short-long sequences.
- **Overdrive pacing at an increased rate after atrial premature beats**.
- **Overdrive pacing at an increased rate after the termination of atrial fibrillation**. This attempts to reduce the immediate reinitiation of the arrhythmia which is a common clinical problem.

Special algorithms

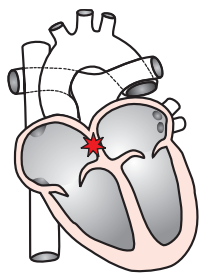


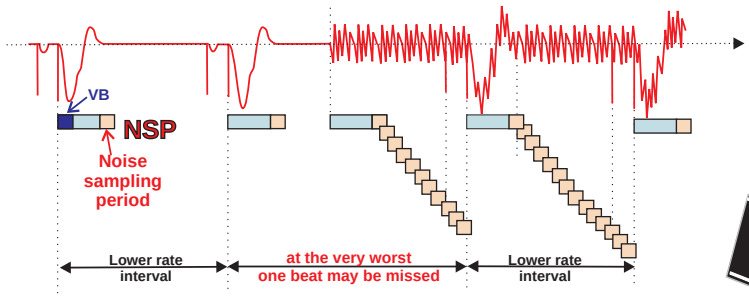
Alternative sites of stimulation

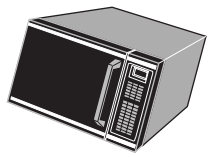
Dual site atrial pacing



Atrial septal pacing

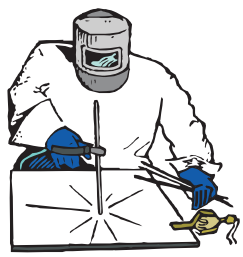


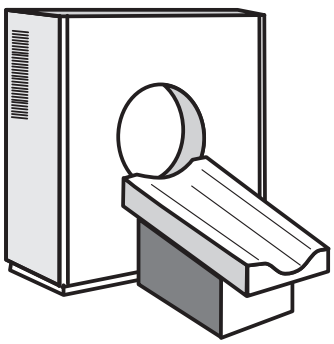




PACEMAKER INTERFERENCE

* Timing cycles - Noise sampling period
* General surgery
* External cardioversion & defibrillation
* Electromagnetic Interference (EMI) inside the hospital
* EMI outside the hospital
* Pacemaker reset

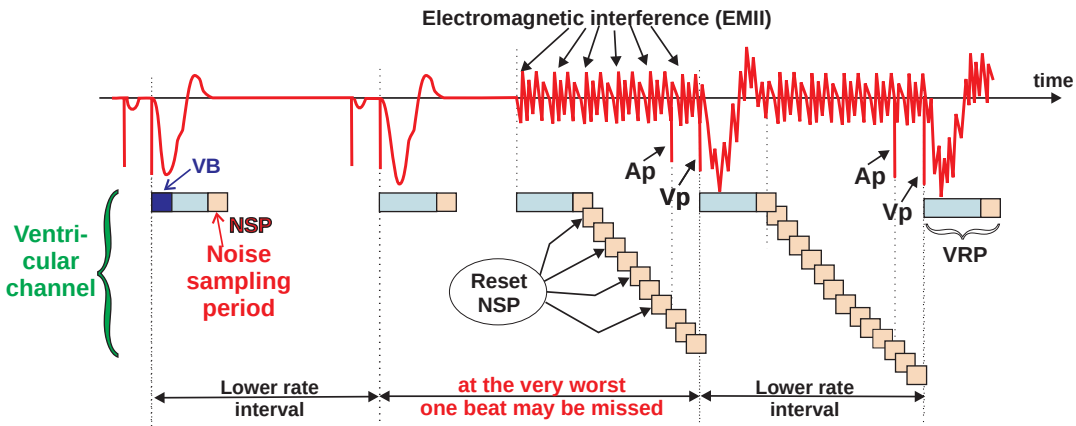




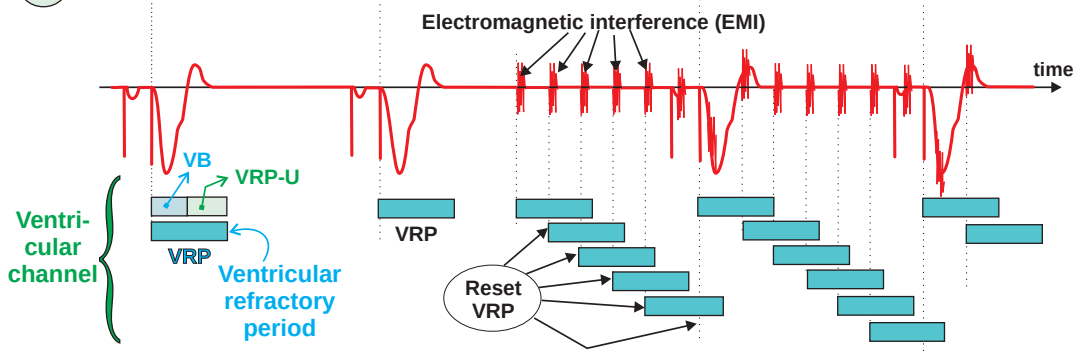
A. F. Sinnaeve

ELECTROMAGNETIC INTERFERENCE & NOISE SAMPLING

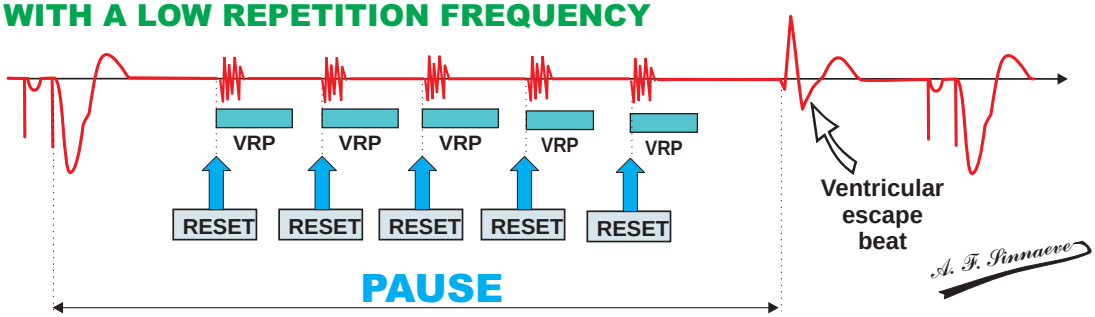
1 RE-INITIATION OF THE NOISE SAMPLING PERIOD



2 RE-INITIATION OF THE TOTAL REFRACTORY PERIOD



NOTE :
THE HAZARD OF PULSED ELECTROMAGNETIC INTERFERENCE WITH A LOW REPETITION FREQUENCY



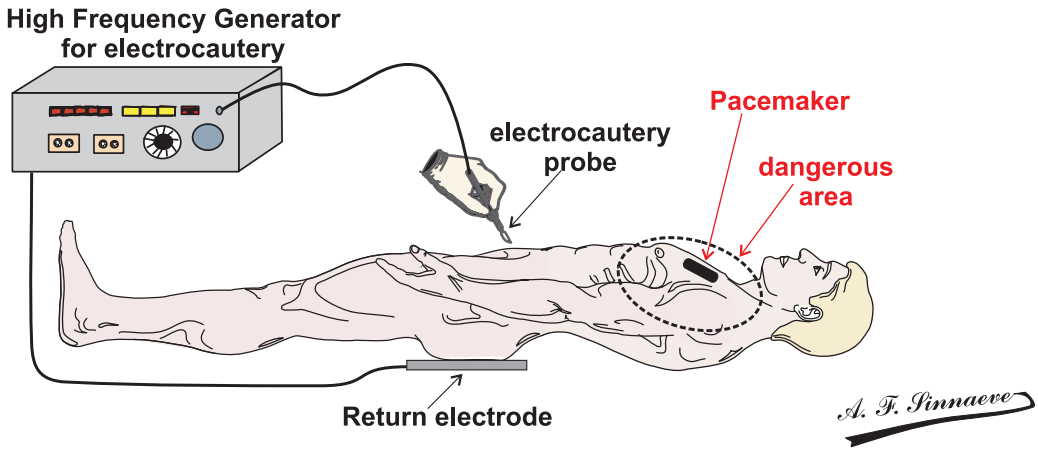
Abbreviations : VB = ventricular blanking period; VRP = ventricular refractory period; VRP-U= unblanked part of VRP; NSP = noise sampling period ; EMI = electromagnetic interference

We have to take some extra precautions.
The guy has a pacemaker !
And don't cut in the insulation of the lead!!!

THE PACEMAKER PATIENT AND GENERAL SURGERY

PRECAUTIONS :

* Avoid electrocautery if possible
* Electrocautery is not to be used within a few inches of the pacemaker and the pacemaker lead !!!
* The return electrode has to be positioned under the buttock away from the pacemaker
* Program the pacemaker to DOO or VOO mode or apply a magnet over the pacemaker
* The pacemaker should be carefully tested after the surgery !!!



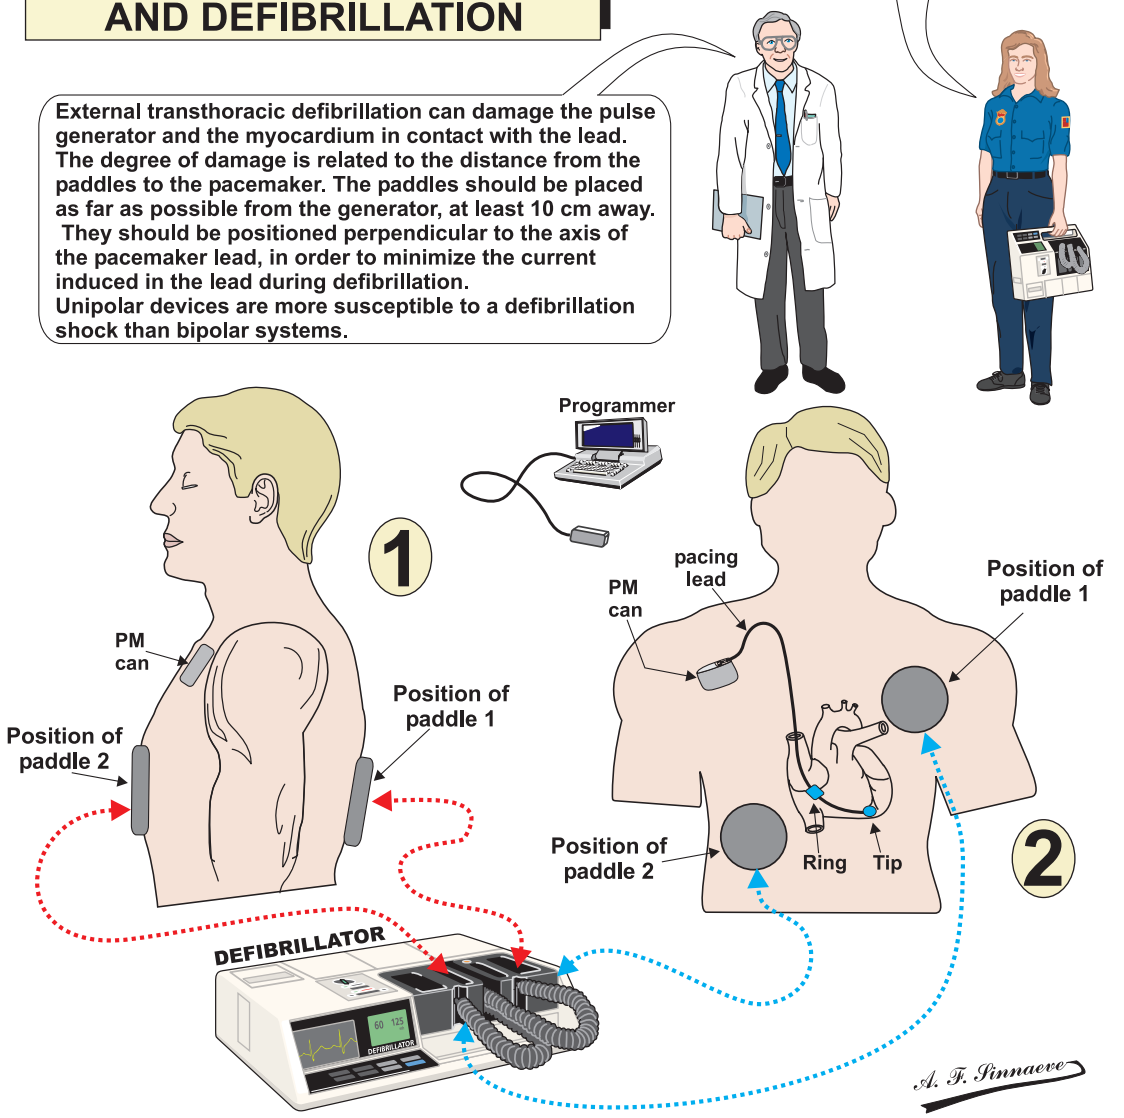
POSSIBLE CONSEQUENCES OF ELECTROCAUTERY IN THE VICINITY OF THE PACEMAKER OR THE LEAD :

* inhibition of the pacemaker
* resetting or reprogramming of the pacemaker
* damage of the pacemaker electronics (eventually causing pacemaker runaway)
* upper rate pacing (especially in rate-adaptive pacemakers based upon impedance measurement such as the minute ventilation sensing)
* current induced in the lead may cause internal burns and scarring, creating a higher pacing threshold or even exit block

EXTERNAL CARDIOVERSION AND DEFIBRILLATION

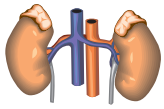
Doctor, how should I position the paddles if my patient has a pacemaker ?

External transthoracic defibrillation can damage the pulse generator and the myocardium in contact with the lead. The degree of damage is related to the distance from the paddles to the pacemaker. The paddles should be placed as far as possible from the generator, at least 10 cm away. They should be positioned perpendicular to the axis of the pacemaker lead, in order to minimize the current induced in the lead during defibrillation.
Unipolar devices are more susceptible to a defibrillation shock than bipolar systems.

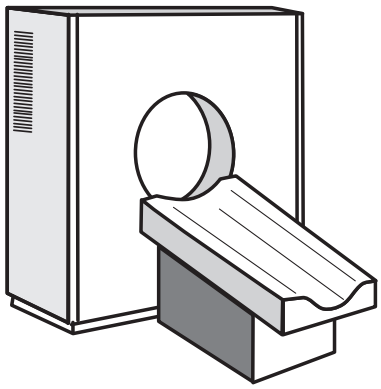


* IMPORTANT : After defibrillation, the device should be interrogated and the programmed parameters compared with those before defibrillation-cardioversion.
* Although all pacemakers have a defibrillation protection circuit, it can be overwhelmed by the extremely high energy of a defibrillation shock. Therefore, it is wise to have a transcutaneous pacemaker nearby.
* A transient rise in threshold can be treated by increasing the output (voltage and pulse duration) of the pacemaker. A prolonged severe increase in ventricular threshold is rare. Transient undersensing is not a serious problem.
* The defibrillation shock can also erase the programmed settings in the memory of the pulse generator. Contemporary devices have a built in protection called “Power On Reset” which automatically reprograms the pacemaker to a safe set of values (normally in VVI mode). The pacemaker is not damaged and can be reprogrammed from the reset mode to its usual parameters.

ELECTROMAGNETIC INTERFERENCE (EMI) INSIDE THE HOSPITAL



MRI
SCANNER
LITHOTRIPSY
RADIOTHERAPY



Extracorporeal Shock Wave Lithotripsy (ESWL) can produce VPCs and it is synchronized to the R wave. The PM should be programmed to VVI, VOO or DOO. The piezoelectric crystal of activity-driven PMs can be shattered if the PM is placed in the focal point of ESWL. Therefore avoid ESWL with abdominal PMs.

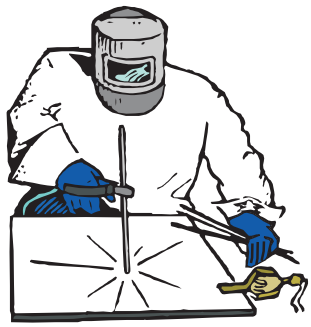
Magnetic Resonance Imaging (MRI) is normally catastrophic for pacemakers and deadly for PM-dependent patients. A pacemaker is still considered as a contraindication for MRI.

Radiotherapy can result in inhibition, tracking and noise reversion when the machine is switched on or off. The ionizing radiation may cause permanent damage to the electronic circuitry of the generator (CMOS structures). Minimize the total dose upon the PM ; maximize shielding and distance of the PM to the radiation beam. Check device function after each therapy session and regularly for several weeks thereafter. Any PM dysfunction after the acute phase may be due to a potentially serious component failure and requires device replacement.

A. F. Sinnaeve

ELECTROMAGNETIC INTERFERENCE (EMI) OUTSIDE THE HOSPITAL

If a PM-dependent patient works in an industrial environment with strong EMI, on-site evaluation may be required. The device manufacturer should be contacted. Holter recordings and pacemaker diagnostics may suffice in non-pacemaker-dependent patients

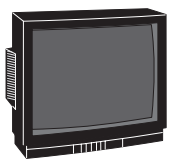


ELECTRIC ARC WELDING

Most common EMI situations are essentially benign for pacemakers !

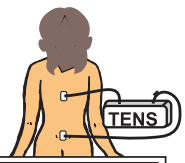
Cellular phones :
The highest risk of interference is when the phone is placed directly over the PM. Minimal interference occurs at the ear position and most interference is eliminated if the phone is kept 8 to 10cm (3 to 4 inches) from the device

Metal detector gates :
Asynchronous pacing or inhibition for 1-2 beats without any ill effects

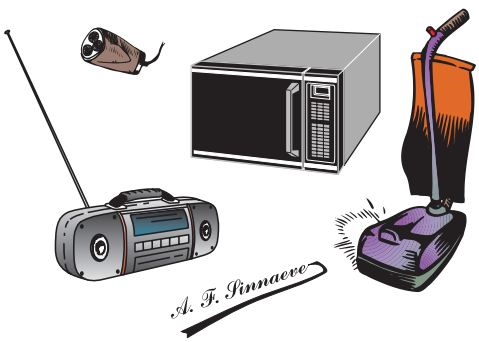


Appliances and Electronics at home (microwave oven, TV remote control, etc.) have normally no effect on contemporary pacemakers

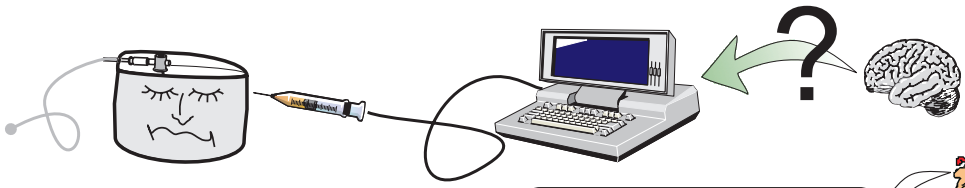
Electronic Article Surveillance (antitheft) : Asynchronous pacing and inhibition for 1-2 beats without any ill effects in most situations. Possible pacemaker reset on rare occasions.



Transcutaneous electrical nerve stimulation may inhibit the pacemaker and require reprogramming of the sensitivity



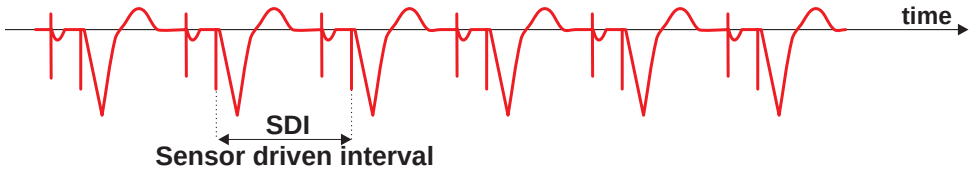
A. F. Simmaco



PACEMAKER RESET

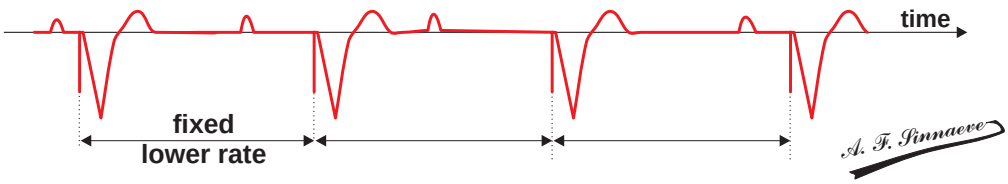
BEFORE RESET

DDDR pacing at a higher sensor driven rate (SDR) with a programmed amplitude and pulse width.



AFTER RESET

VVI pacing at a special fixed lower rate defined by the manufacturer and at nominal amplitude and pulse width.

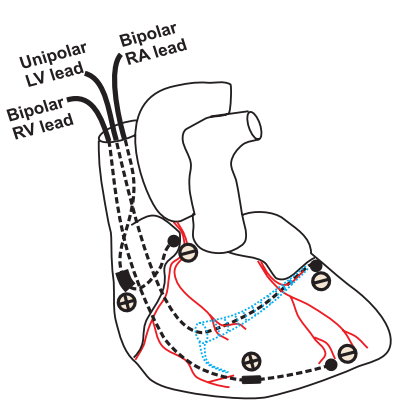


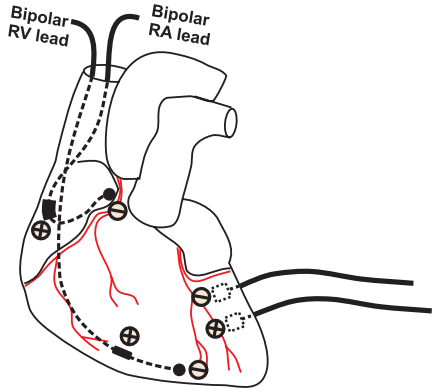
CAUTION

Reset may be poorly tolerated in patients hemodynamically dependent on AV synchrony !!!

*** Reset is reversible by programming ! No permanent damage is done to the pacemaker.**
*** Pacemaker reset may be due to therapeutic radiation, electrocautery, heavy electro-magnetic interference and defibrillation shock.**
*** High level interference may erase the pacemaker programs that are stored in RAM, but do not affect the safety programs stored in ROM.**
*** Reset must be differentiated from ERT (check the battery voltage and impedance !)**

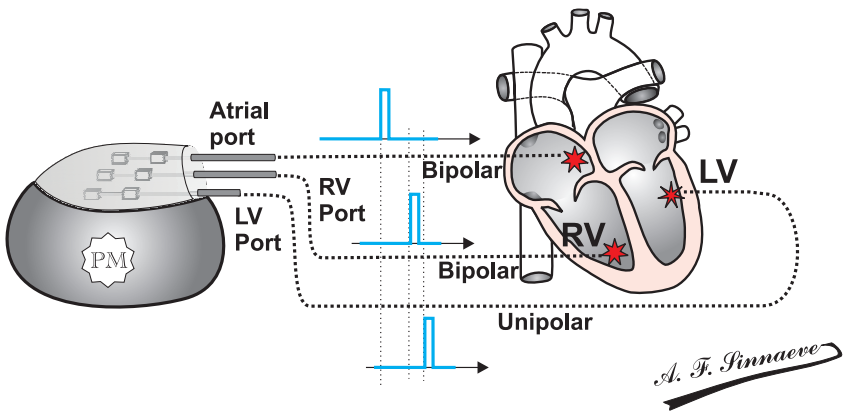
Abbreviations : ERT = elective replacement time (just before battery depletion) ; RAM = random access memory (can be changed by the programmer) ; ROM = read only memory (a fixed content that can only be read by the microprocessor inside the pacemaker)





BIVENTRICULAR PACING (BiV)

* Cardiac resynchronization - General concepts
* Leads for BiV pacing
* Types of BiV pacemakers
* Mean QRS axis in the frontal plane
* BiV pacing - ECG patterns
* ECG evaluation - Diagnosis of capture
* Pacing impedance of BiV pacing systems
* Pre-empted or aborted Wenckebach response



CARDIAC RESYNCHRONIZATION or MULTISITE PACING

Cardiac resynchronization refers to stimulation techniques that change the degree of atrial and ventricular electromechanical asynchrony in patients with major intra-atrial or interatrial and ventricular conduction disorders. Atrial and ventricular resynchronzation is usually accomplished by pacing from more than one site in an electrical chamber either simultaneously or one site before the other (pre-excitation).

ATRIAL RESYNCHRONIZATION

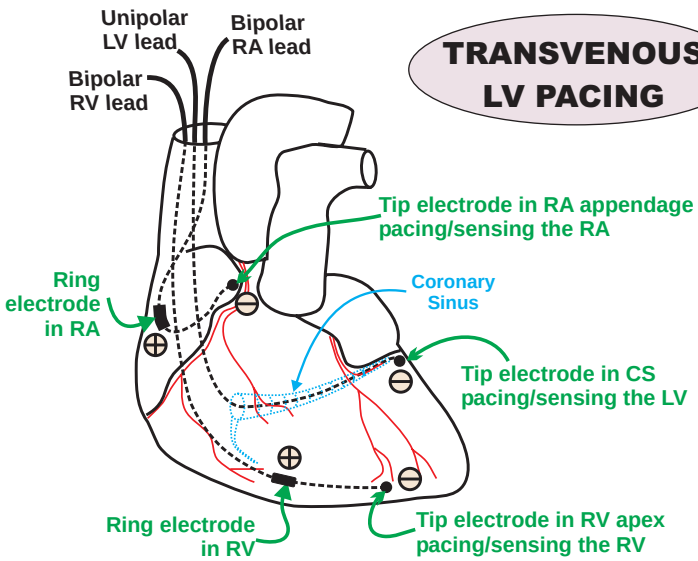
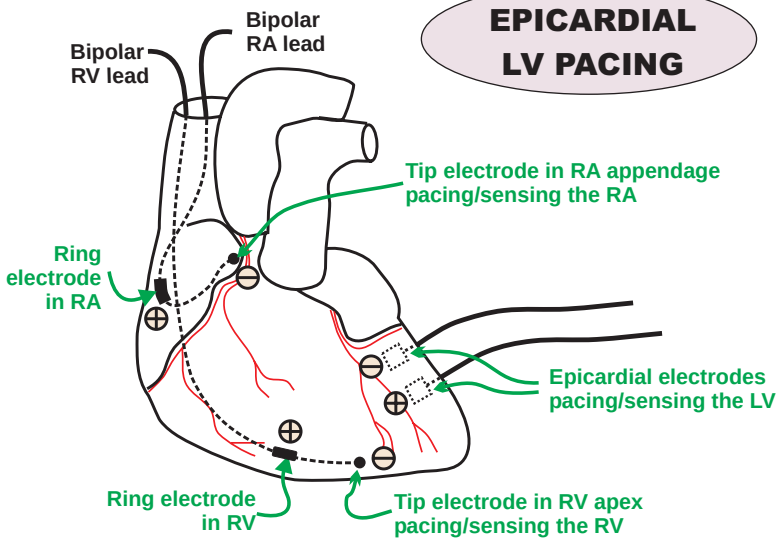
LEADS AND ELECTRODES FOR BIVENTRICULAR PACING

A 3 chamber pacemaker for congestive heart failure ! What will they think of next ?

TRANSVENOUS LV PACING



EPICARDIAL LV PACING

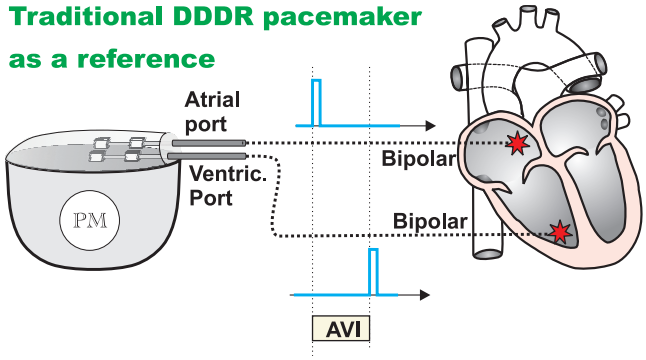


A. F. Sinnaeve

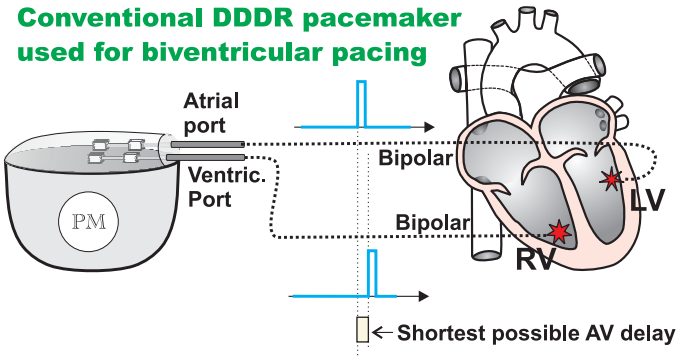
Abbreviations : CS =coronary sinus; LV = left ventricle; RA = right atrium; RV = right ventricle

BIVENTRICULAR PACING SYSTEMS

Traditional DDDR pacemaker as a reference



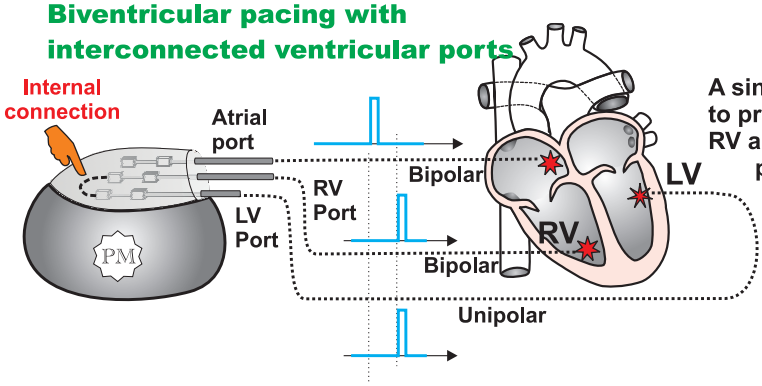
Conventional DDDR pacemaker used for biventricular pacing



This can only be used in patients with permanent atrial fibrillation.

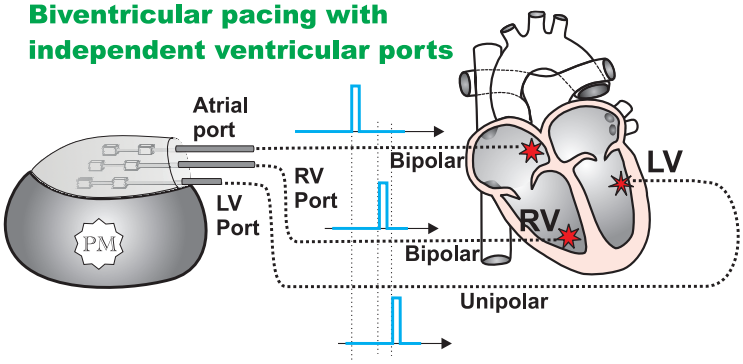
The shortest AV interval (0 - 30 ms) should be programmed.

Biventricular pacing with interconnected ventricular ports



A single ventricular output is divided to provide simultaneous pacing of RV and LV (dual cathodal system with parallel outputs). The pacemaker senses RV and LV activity simultaneously.

Biventricular pacing with independent ventricular ports



The time delay between the LV and RV stimuli may be programmed and optimized for each patient.
Each ventricle has its own sensing and output circuits.

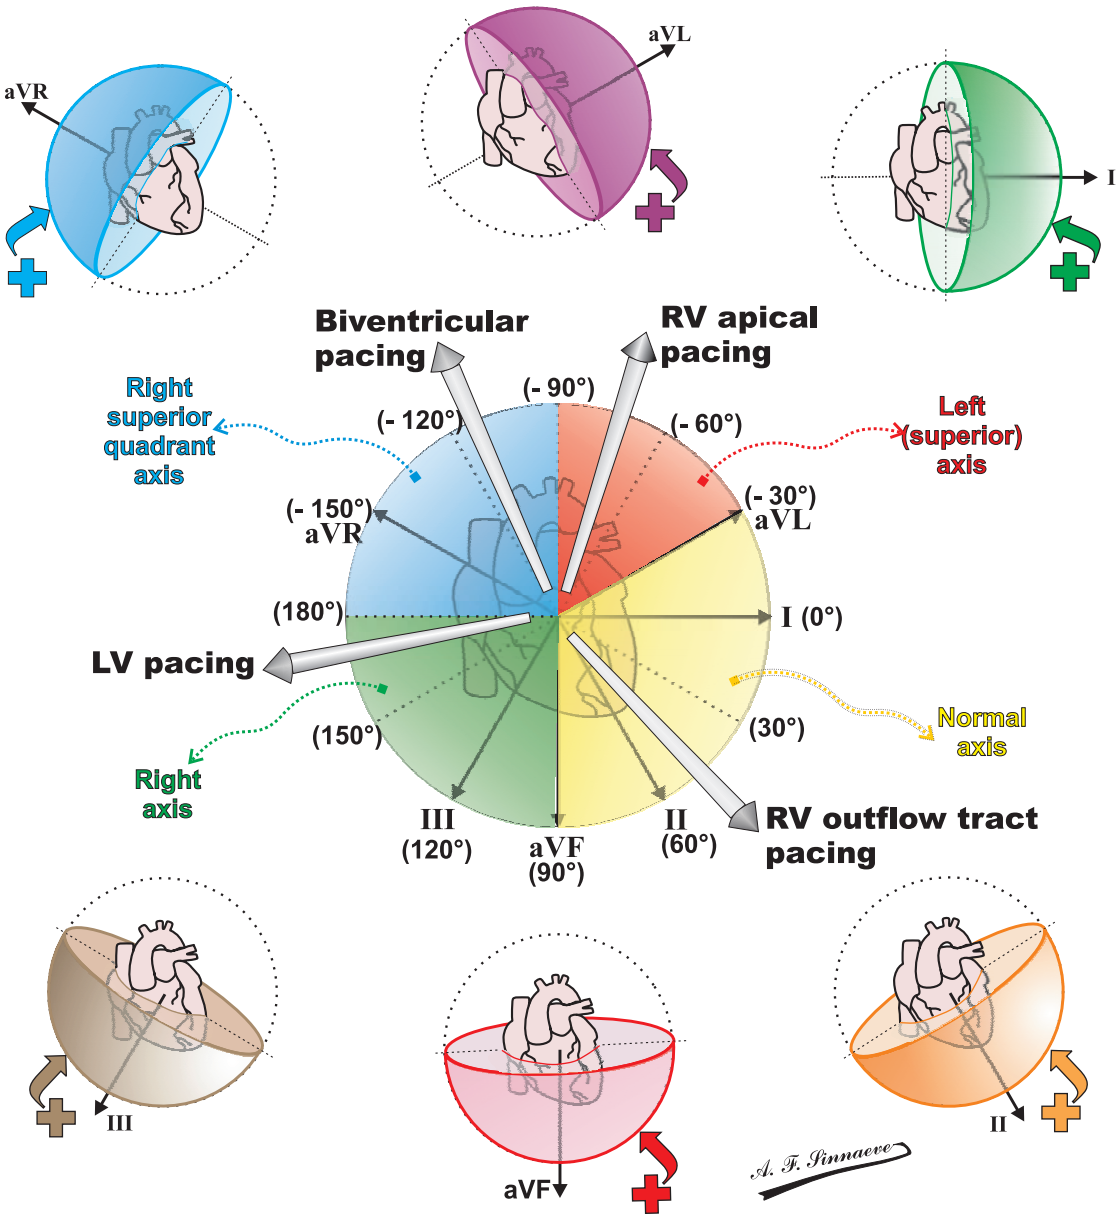
Abbreviations :
LV = left ventricle ; RV = right ventricle

THE MEAN QRS AXIS IN THE FRONTAL PLANE DURING CARDIAC PACING

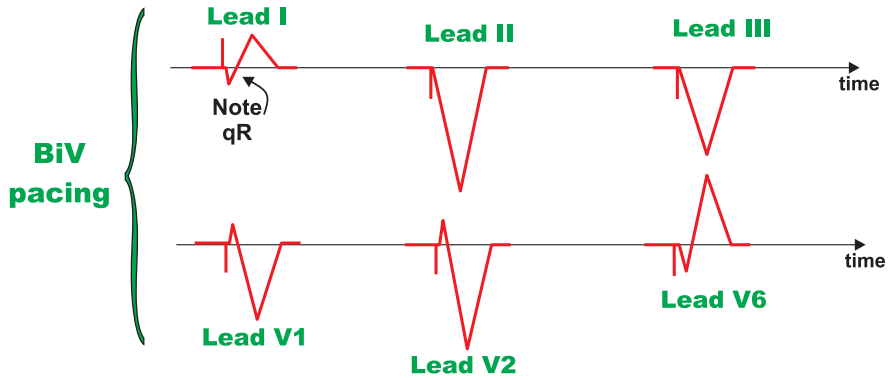
During pacing the mean frontal plane QRS axis reflects the site of the pacing :

*** for RV pacing : apex vs outflow tract**

*** for biventricular pacing : RV only, LV only or biventricular**

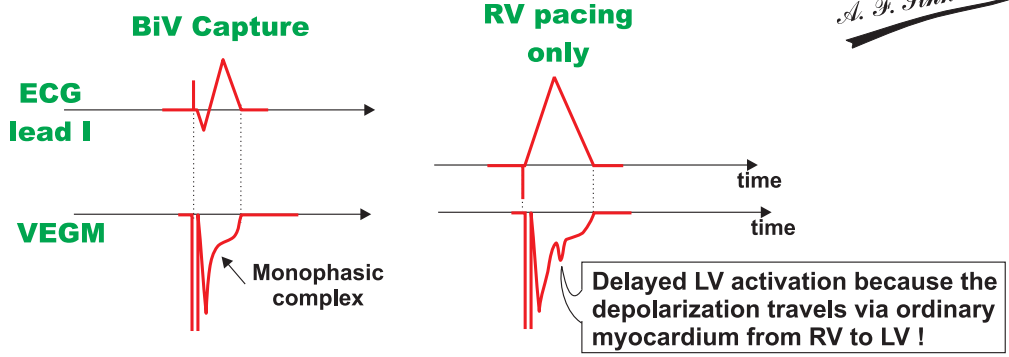


BIVENTRICULAR (BiV) PACING



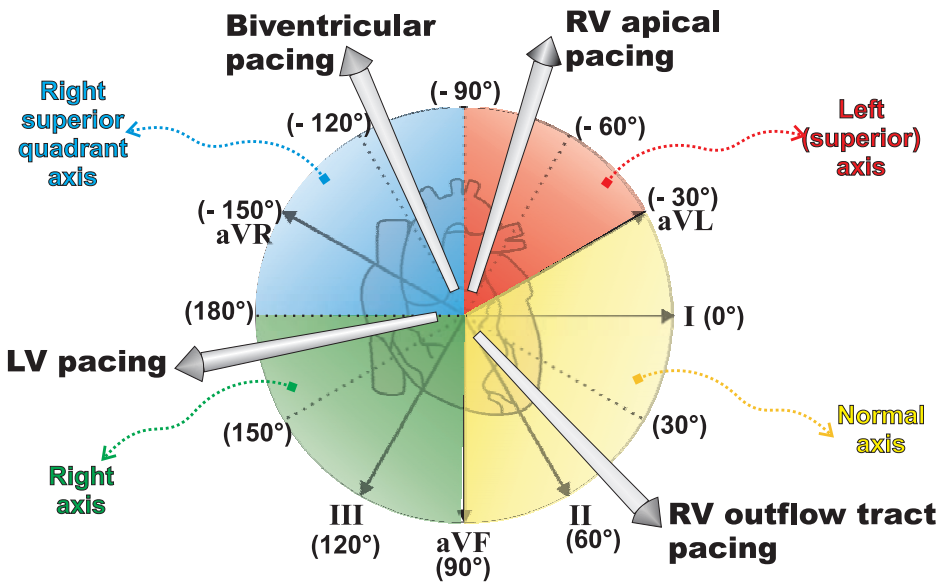
To show ventricular capture in pacemakers with a common output, lower the voltage and/or the pulse width. The left ventricle (LV) will lose capture first in almost all cases because pacing threshold is higher than that of the right ventricle (RV).
Loss of capture in one ventricle will cause a change in the morphology of the beats in the 12-lead ECG. Examination of a single lead may be misleading.

A. F. Sinnaeve

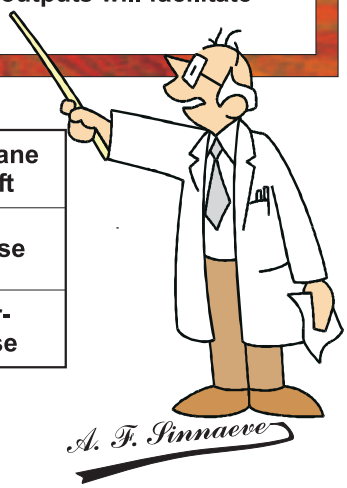


* A change in frontal plane axis may corroborate loss of capture in one ventricle
* Simultaneous recording of ECG, markers and ventricular electrogram (VEGM) is very helpful
* Beware of ventricular fusion beats with the conducted spontaneous QRS complex. The absence of fusion is verified by shortening the AV delay whereupon no change in QRS morphology should take place

ECG EVALUATION OF BIVENTRICULAR PACING



1. Establish a template for the best ECG lead showing morphological differences in RV, LV and BiV pacing. Store the pattern and use it for follow-up.
2. More than one lead is needed to confirm capture. Leads I and III are often enough. Make sure the leads are properly connected. Consider a 12-lead ECG in all cases.
3. Do the threshold test in the DDD mode with a short AV delay or in the VVI mode (if tolerated) at a rate higher than the intrinsic rate.
4. When in doubt, start at the maximum output (voltage and pulse duration) to ensure pacing of RV and LV.
5. Newer devices with separately programmable RV and LV outputs will facilitate ECG interpretation.



Pacing site	QRS in Lead I	QRS in Lead III	Frontal plane axis shift
BiV → RV	Greater positivity	Greater * negativity	Clockwise
BiV → LV	Greater negativity	Greater positivity	Counter-clockwise

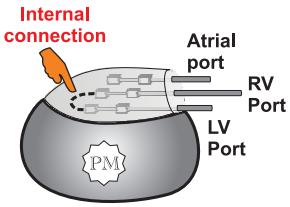
* QRS in lead III is more negative than in lead II

Abbreviations : BiV = biventricular ; LV = left ventricle ; RV = right ventricle

THE PACING IMPEDANCE OF BIVENTRICULAR PACING SYSTEMS

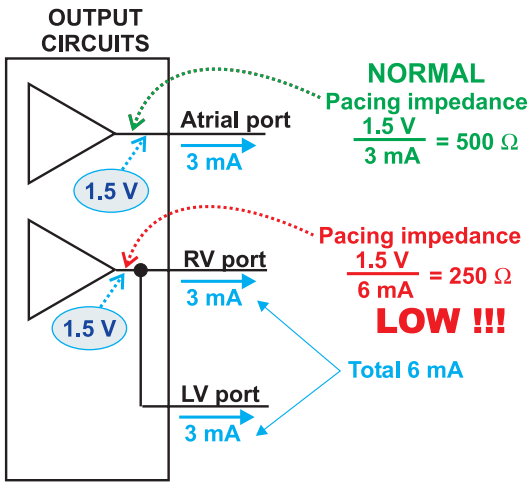
The values for voltage (1.5 V), current (3 mA) and lead impedance (500 Ω) are arbitrarily choosen as an example

Biventricular pacing with interconnected ventricular ports

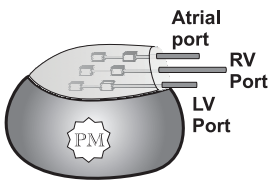


The two ventricular leads are in parallel

$$\frac{1}{R_{tot}} = \frac{1}{R_1} + \frac{1}{R_2}$$

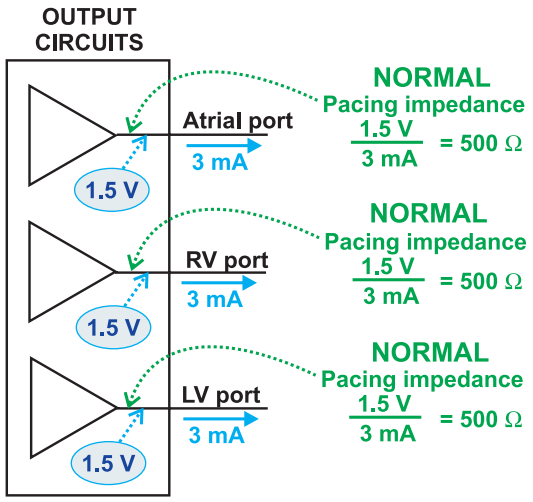


Biventricular pacing with independent ventricular ports



Most PM workers favor high impedance leads !!!

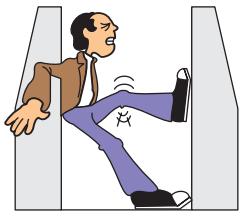
A. F. Sinnaeve



BEWARE : DIAGNOSIS OF LEAD PROBLEMS IN BIVENTRICULAR SYSTEMS

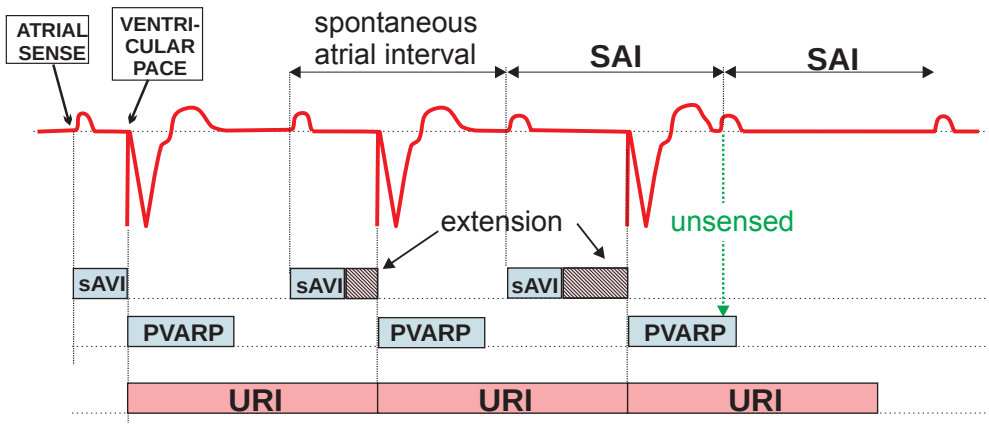
The total lead impedance may be low (in the range of 250 to 400 Ω) in a normally functioning biventricular system. A mechanical problem in one of the ventricular leads but not in the other, may not be readily detectable using standard impedance criteria. A conductor fracture involving one lead will not result in the very high impedance seen with single chamber pacing. Rather, that lead will effectively be taken out of the system and the measured impedance will reflect that of the intact ventricular lead. Hence, with a lead fracture in one of the two ventricular leads, the impedance may rise to the normal range for a univentricular lead.

The low telemetered impedance seen with an insulation failure in a single chamber lead may be the "normal" range during intact biventricular pacing. The normally low impedance in a dual cathodal system may thus complicate the diagnosis of an insulation failure in one of the leads.

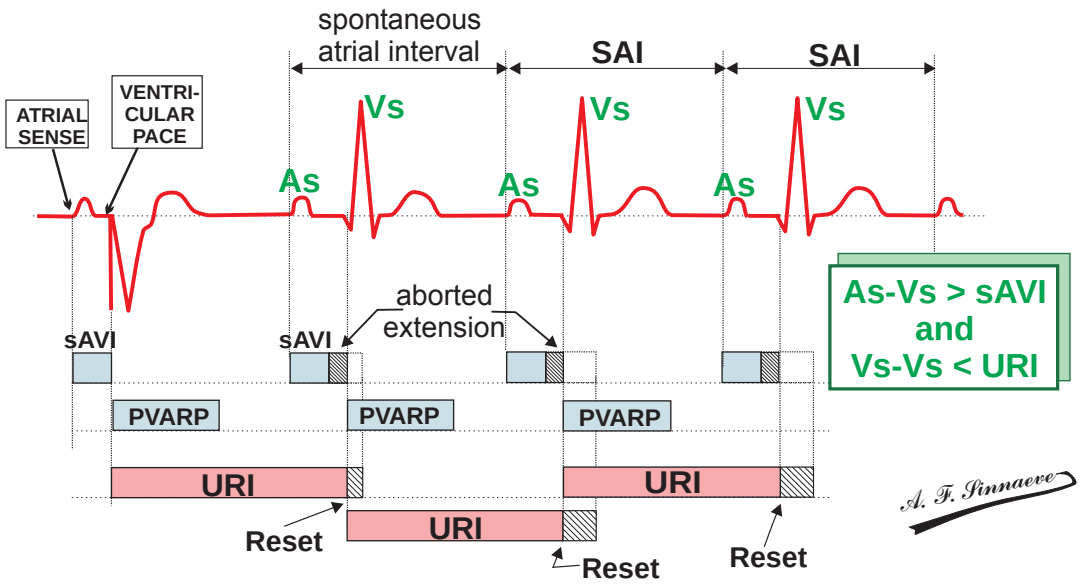


THE PRE-EMPTED or ABORTED WENCKEBACH BEHAVIOR

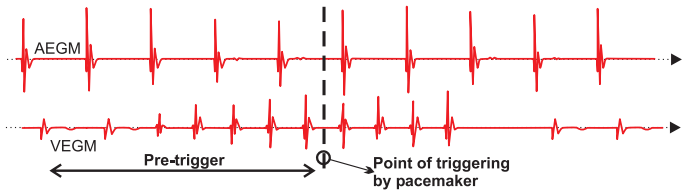
Normal upper rate response of the Wenckebach type



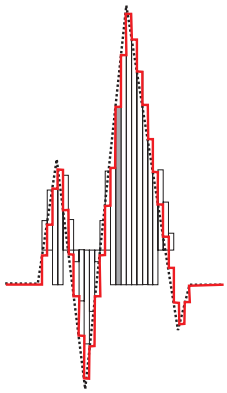
The pre-empted Wenckebach behavior with short sAVI

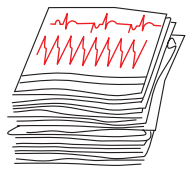


Abbreviations : As = atrial sense; Vs = ventricular sense; sAVI = AV delay after sensing; PVARP = postventricular atrial refractory period; URI = upper rate interval; SAI = spontaneous atrial interval



PACEMAKER FOLLOW-UP





* Pacemaker implantation
* Requirements for follow-up
* Central role of ventriculoatrial (VA) conduction
* Central role of postventricular atrial refractory period (PVARP)
* Transtelephonic follow-up
* General approach - part 1
* General approach - part 2
* Systematic follow-up - Various steps
* Automatic threshold determination - Initial steps
* Automatic threshold determination - End active phase

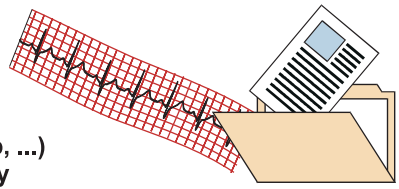
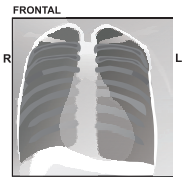
A. F. Sinnaeve

PACEMAKER IMPLANTATION

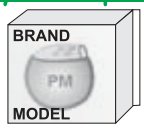
Have the patient's chart :

* Indication for pacemaker
* Medications
* Allergies
* Laboratory tests (INR, blood group, ...)
* Latest 12-lead ECG and chest X ray



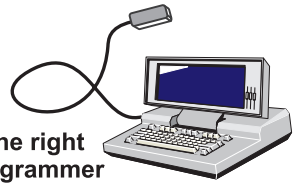


Make sure that the right pacemaker, leads, manual, and programmer are at your disposal

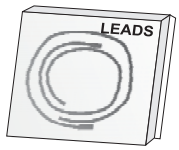


Sterile pacemaker

Technical manual provided by the pacemaker manufacturer



The right programmer



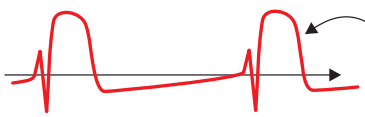
Sterile leads

Measure, verify and adjust

Use a PSA or Pacemaker System Analyzer permitting measurements of the output and the sensitivity of the pacemaker to be implanted and the thresholds and R- and P-wave characteristics of the implanted leads. The PSA also measures impedance

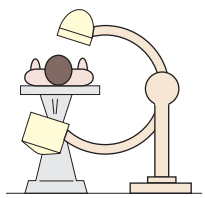
ACCEPTABLE VALUES AT IMPLANTATION	Atrial	Ventricular
Voltage threshold (at 0.5ms pulse width)	<1.5V	<0.5V
Sensitivity (signal amplitude)	>1.5mV	>5mV
Pacing impedance (at 5V and 0.5ms)°	<750Ω	<750Ω
Slew rate (only measured if the amplitude is small)	>0.5V/s	0.5V/s

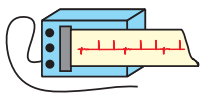
° Special high impedance leads will register a higher impedance (consult manufacturers notes)

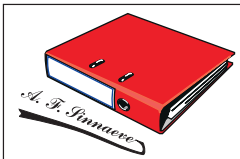


ST-segment shift due to current of injury indicates good endocardial contact of RV. This ensures a low pacing threshold.
(Unipolar electrogram from tip electrode)

* Try pacing near threshold with deep respiration and coughing and look for eventual unstable position of the leads
* Look at lateral or near lateral fluoroscopy to document the anterior position of the right ventricular lead and/or atrial lead if positioned in the right atrial appendage
* If there is sensing when the pacemaker is placed in the subcutaneous tissue, apply the magnet to make sure that both channels are capable of pacing
* Pace both A and V at 10V to rule out diaphragmatic stimulation
* Take a 12-lead ECG to make sure that the ventricular lead does not pace the left ventricle
* Look for retrograde VA conduction at the time of implantation or later before hospital discharge.





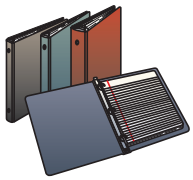


* Take a permanent chest x-ray soon after implantation for lead position and to rule out pneumothorax
* Interrogate the PM and reprogram if necessary; make a print-out for the patient's file
* Document all implantation data in the patient's chart

SYSTEMATIC PACEMAKER FOLLOW-UP

Requirements

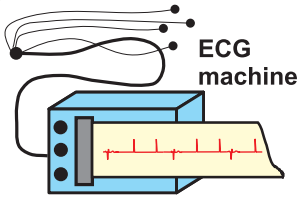
Technical manuals provided by pacemaker manufacturers



Planner

Magnets

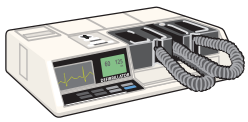
Official guidelines for pacemaker follow-up (e.g. NASPE)

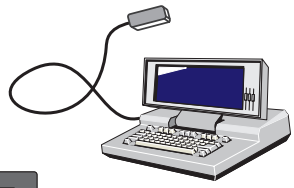


ECG machine

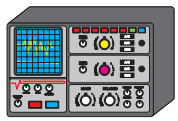
Programmers

External defibrillator

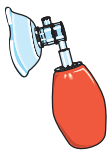




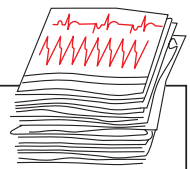
Scope & electronic counter to measure spontaneous and magnet automatic intervals



Crash cart for emergencies



HISTORY & PHYSICAL EXAMINATION
are part of pacemaker follow-up



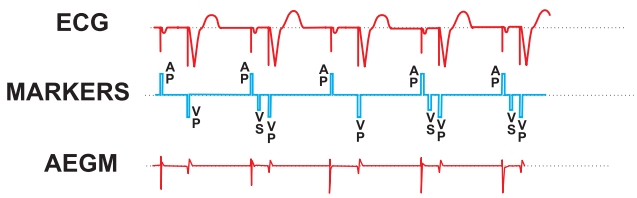
Thou shalt take long rhythm strips and thou shalt be rewarded to the fullness of thy days !

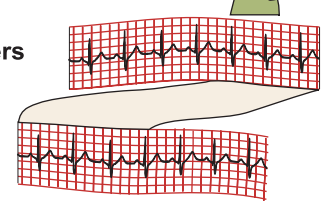
12-LEAD ECG WITH AND WITHOUT MAGNET

1. Verify automatic interval with and without magnet application
2. Estimate degree of pacemaker dependence
3. Verify appropriate depolarization sequence, capture, sensing, fusion and pseudofusion beats

MARKERS & INTRACARDIAC ELECTROGRAMS

Make a simultaneous recording of ECG annotated markers and intracardiac electrograms





A. F. Sinnaeve

IMPACT OF RETROGRADE CONDUCTION IN CARDIAC PACING

PACEMAKER SYNDROME

HEMODYNAMIC DISADVANTAGE

ENDLESS LOOP TACHYCARDIA (ELT)

REPETITIVE NONREENTRANT VA SYNCHRONY (RNRVAS)

VA CONDUCTION
100-400 ms
rarely longer

INFLUENCED BY AUTONOMIC FACTORS, DRUGS, etc.

MAY PROLONG WITH INCREASE IN HEART RATE

RARELY OCCURS ONLY ON EXERCISE

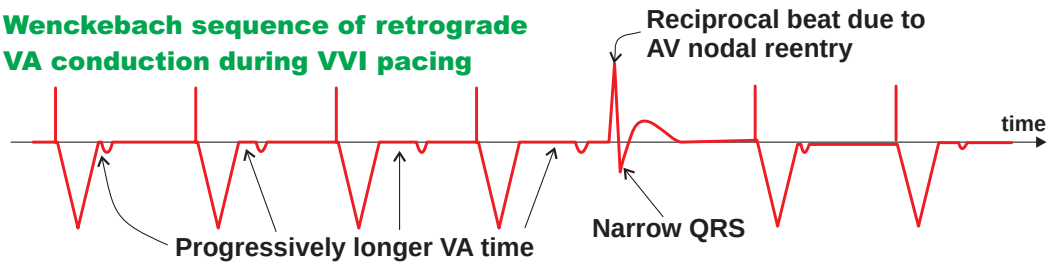
OCCURS IN :
70-80 % of SSS pts
35 % of AV block pts

MANIFESTATIONS OF SUSTAINED VA CONDUCTION

* Regular 1 : 1 VA conduction
* Regular or irregular 2 : 1, 3 : 1 VA conduction
* Regular Wenckebach phenomenon of VA conduction

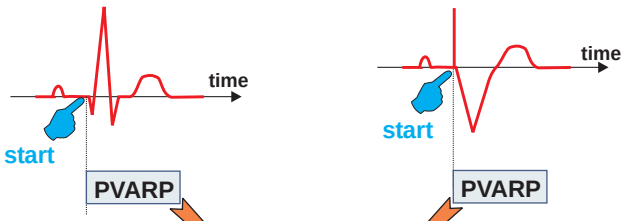
A. F. Sinnaeve

Wenckebach sequence of retrograde VA conduction during VVI pacing



Abbreviations : AV = atrioventricular (anterograde or orthograde); VA = ventriculoatrial (retrograde); SSS = sick sinus syndrome; pts = patients

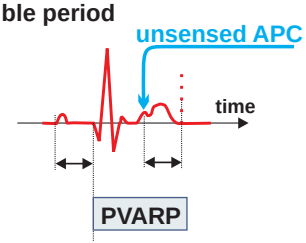
THE CENTRAL ROLE OF THE POSTVENTRICULAR ATRIAL REFRACTORY PERIOD (PVARP) IN DUAL CHAMBER PACING



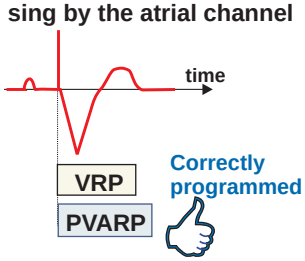
PVARP

OPTIMAL ATRIAL SENSING

Prevents sensing of early atrial events thereby avoiding delivery of a ventricular stimulus on the T wave and ventricular vulnerable period

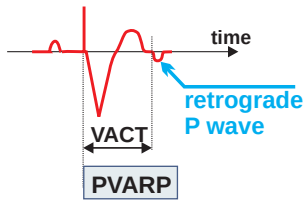


PVARP should not be shorter than the ventricular refractory period (VRP) so as to avoid far-field sensing by the atrial channel

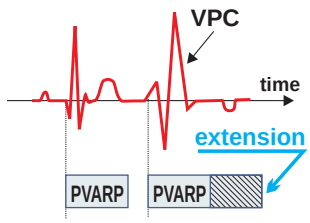


PREVENTION OF ENDLESS LOOP TACHYCARDIA

Program PVARP to = VACT + 50 ms (VACT = VA conduction time) (does not prevent retrograde VA conduction)



Automatic PVARP extension with recognition of ventricular premature complex (VPC)



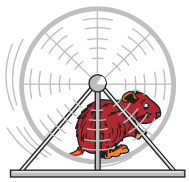
CONTROL OF UPPER RATE

TARP = AVI + PVARP

If there is no separately programmable upper rate

$$\text{Upper rate (bpm)} = \frac{60{,}000}{\text{TARP (ms)}}$$

Or 2:1 blocking rate if there is a separately programmable upper rate



A. F. Sinnaeve

Abbreviations : VA = ventriculoatrial; APC = atrial premature complex; TARP = total atrial refractory period; VRP = ventricular refractory period

GENERAL APPROACH TO FOLLOW-UP PART 1

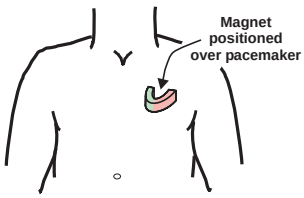
1 EXAMINATION & PATIENT HISTORY

A clinical approach is very important !!!

2 BLOOD PRESSURE

The pacemaker syndrome causes a fall in blood pressure during pacing !!!

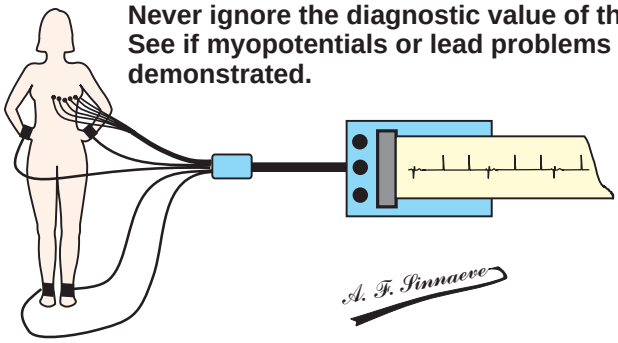
3 APPLICATION OF THE MAGNET

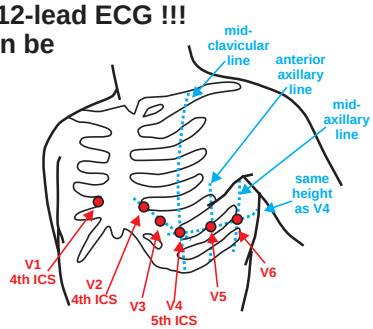


1. **Asynchronous pacing at the magnet rate. The rate and mode (DOO or VOO for dual chamber pacemakers) are device specific.**
2. **AV interval usually shortens**
3. **The magnet rate (which may differ from the programmed rate according to design) reflects the status of the battery and indicates an intensified follow-up period, ERT and EOL**
4. **Some devices allow the magnet response to be programmed on or off**

4 VERIFY THE ECG THOROUGHLY

Never ignore the diagnostic value of the 12-lead ECG !!!
See if myopotentials or lead problems can be demonstrated.

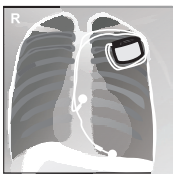




Abbreviations : DOO= Dual chamber AV sequential asynchronous mode; VOO = Ventricular asynchronous pacing mode; ECG = Electrocardiogram; EOL = End-of -Life; ERT = Elective Replacement Time; ICS = intercostal space

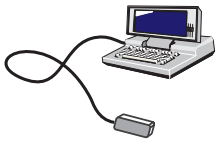
GENERAL APPROACH TO FOLLOW-UP PART 2

5 EXAMINE THE CHEST X- RAY



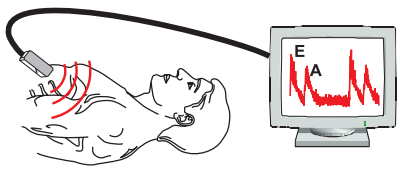
1. Identification of manufacturer and model if unknown
2. Check for lead position
3. Check for lead fracture
4. Check for LV failure

6 USE THE PROGRAMMER



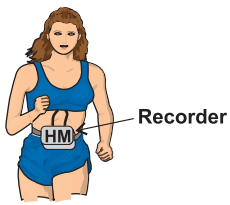
Match the programmer with the pacemaker !!!

7 ECHOCARDIOGRAPHY



1. Anatomic
   a. Diagnosis of unusual lead position such as LV site best documented by TEE
   b. Ventricular lead perforation (with possible pericardial effusion)
2. Hemodynamic
   a. Optimization of AV delay
   b. Evaluation of biventricular pacing

8 HOLTER MONITORING



To complement data in pacemaker memory in patients who remain symptomatic

9 TREADMILL or WALKING TEST

* Evaluation of atrial chronotropic incompetence
* Optimize sensor programming
* Evaluation of special functions on exercise : biventricular pacing, pacing for hypertrophic cardio-myopathy, etc.

A. F. Sinnaeve

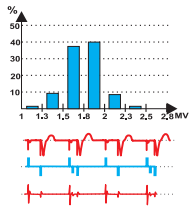
Abbreviations : AV = atrioventricular; LV = left ventricular; TEE = transesophageal echocardiography

SYSTEMATIC PACEMAKER FOLLOW-UP

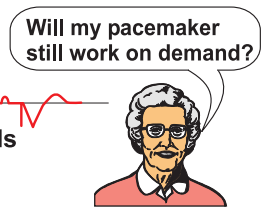
Make sure that the programming head is positioned carefully over the pacemaker

PACEMAKER INTERROGATION

1. Verify the administrative data
2. Check on the programmed data
3. Examine the measured or real-time data { Output ? Battery ? Leads ?
4. Inspect the memorized data



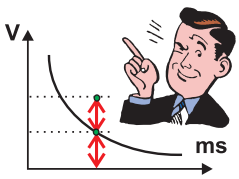
A higher sensitivity means a lower number in mV !



DETERMINATION OF SENSING THRESHOLDS

1. Automated and/or manual determination of sensing thresholds is needed if patient has periods of spontaneous rhythm
2. Reprogram sensitivity as necessary

Make sure that the safety margin is adequate !



DETERMINATION OF PACING THRESHOLDS

1. Automated and/or manual determination of pacing thresholds
2. Reprogram voltage and/or pulse duration as necessary

CHECK THE SPECIFIC FUNCTIONS

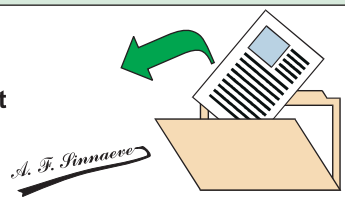
1. Check for crosstalk
2. Evaluate retrograde VA conduction and propensity to endless loop tachycardia
3. Look for eventual myopotential interference interference in unipolar PMs
4. Examine rate-adaptive function, sleep rate, hysteresis, automatic mode switching, histogram settings, etc.

IF NECESSARY ORDER SPECIAL TESTS : Chest X ray, Holter, etc.

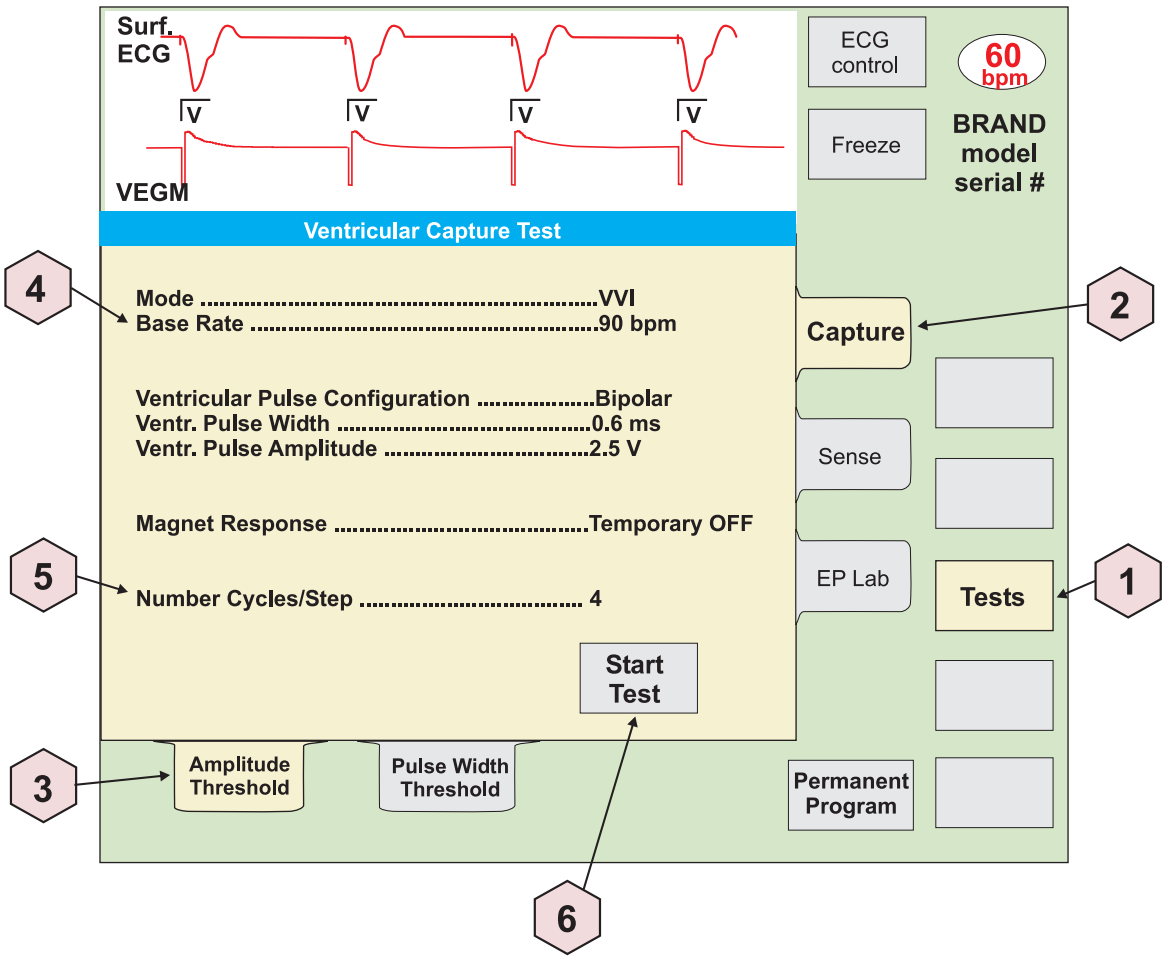
PREPARE YOUR REPORT

Meticulous record-keeping is necessary

1. Clear the appropriate memorized data
2. Make the final print-outs
3. Compare final parameters with those at presentation
4. Give the patient a copy of the print-out



AUTOMATIC DETERMINATION OF THRESHOLD
INITIAL STEPS



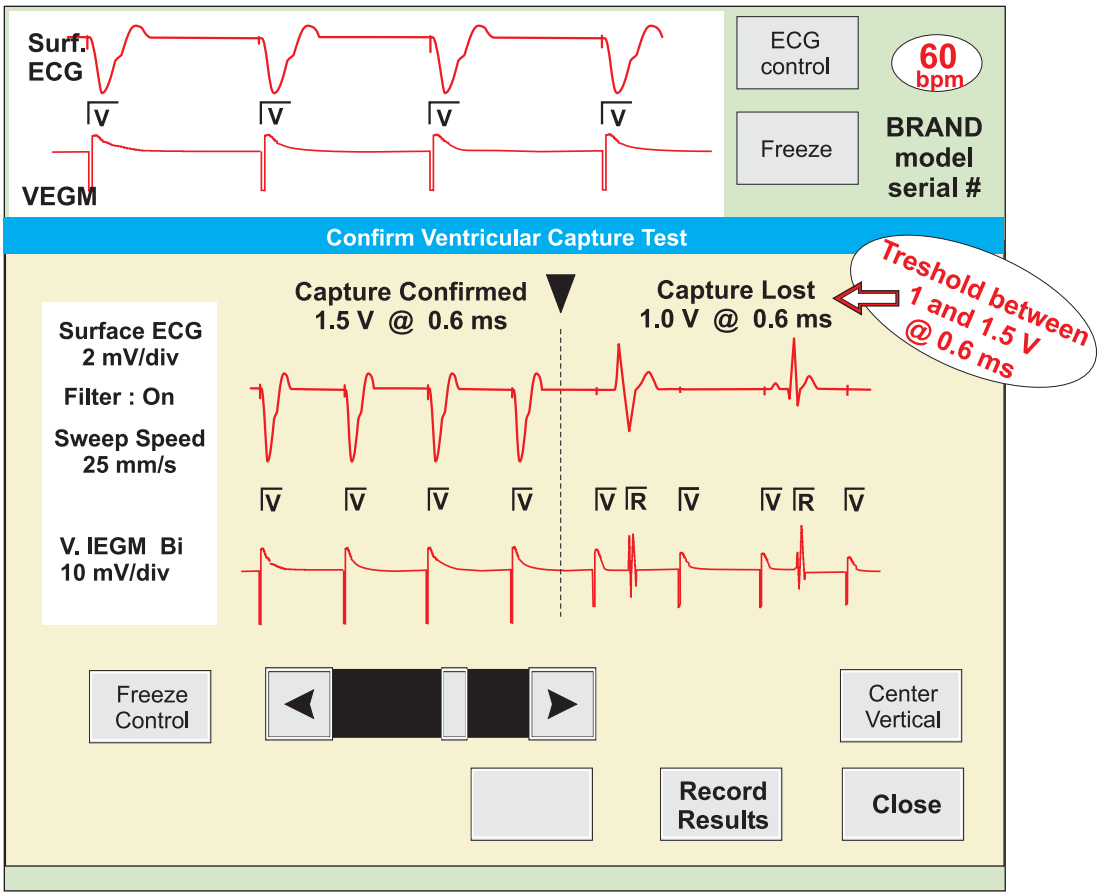
* Initial Step 4 : The actual "Base Rate" (60) indicated in red in the upper right corner is programmed to a higher temporary value (90) above the patient's intrinsic rate to ensure pacing

*Initial Step 6 : When {Start Test} is touched, a "Test in Progress" message will appear with two option buttons {End Test} and {Stop Test}. The {Stop Test} is the emergency button, immediately restoring the settings to the previously programmed values

* When capture is lost, touching {End Test} terminates the test and restores the previously programmed value (amplitude or pulse width). The system then displays the "Confirm Capture Test" screen and stores the test in the memory of the programmer.

A. F. Sinnaeve

AUTOMATIC DETERMINATION OF THRESHOLD END OF ACTIVE PHASE



* During the test the temporary actual rate (90) is indicated in red in the upper right corner. At the end of the test, the programmed "Base Rate" (60) is restored.

* The test will start at a value (amplitude or pulse width depending upon choice) one step lower then the prevailing value. After every programmed "Number Cycles/Step", the value of the test parameter will decrease by one step. Each step is indicated by the appearance of a vertical line on the ECG display.

* Pressing {End Test} not only terminates the test, but restores the previously programmed values, i.e. 2.5 V - 0.6 ms - 60 bpm. These settings may be checked in the upper part of the display

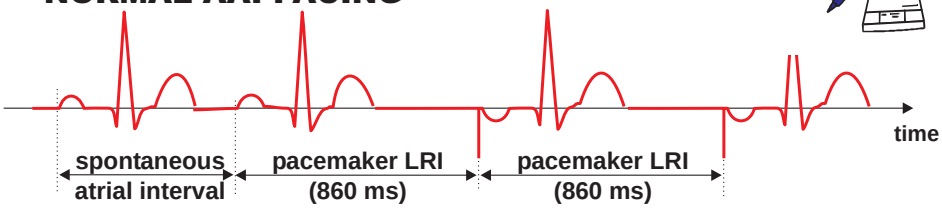
* After touching {Close} the pacemaker should be programmed to yield a suitable safety margin for reliable long-term pacing (confirm with {Permanent program})

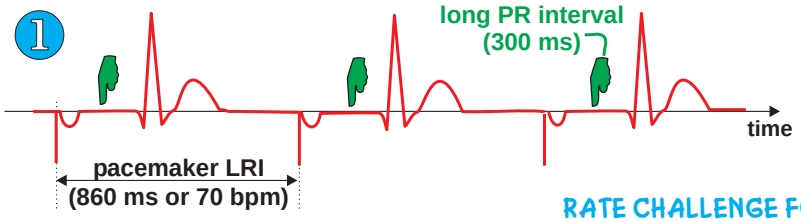
A. F. Sinnaeve

You know, even in carefully selected patients for AAI and AAIR pacemakers, there is always a small but definite risk of second- and third-degree AV block with the passage of time. The status of AV conduction must be carefully evaluated during follow-up to detect the earliest manifestations of potentially serious AV block that may require upgrading to a dual chamber pacemaker.

AAI PACEMAKERS AND THEIR FOLLOW-UP

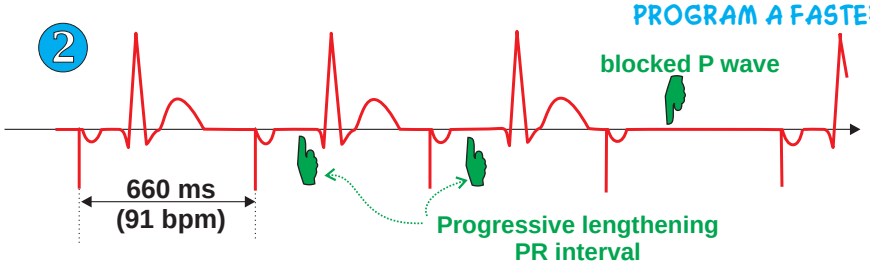
NORMAL AAI PACING



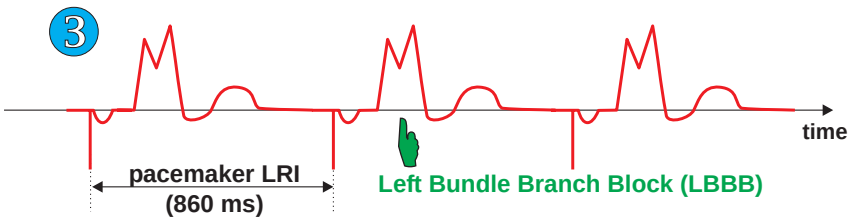


Marked 1st degree AV block

RATE CHALLENGE FOR AV CONDUCTION !!!
PROGRAM A FASTER LOWER RATE.



Wenckebach type I second-degree AV block



Beware of new bundle branch block

A. F. Sinnaeve

Abbreviations : LRI = lower rate interval ; LBBB = left bundle branch block ; AAI = atrial demand pacemaker mode ; AAIR = atrial demand rate-adaptive pacemaker mode

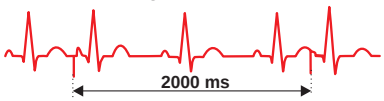
APPLICATION OF THE TRIGGERED PACING MODE

Remember that a DDD pacemaker functions in the triggered mode in the atrium because atrial sensing triggers a ventricular output after a delay equivalent to the programmed AV interval. In the AAT or VVT modes triggering occurs immediately after sensing without delay so that the pacemaker stimulus falls within the sensed event, P wave or QRS complex.

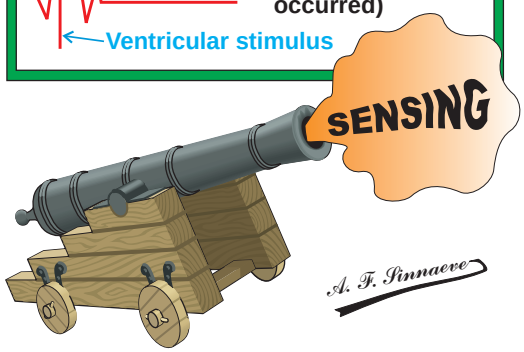
DDD pacemaker (basic or lower rate 60 bpm)
Is the atrial channel correctly sensing ?

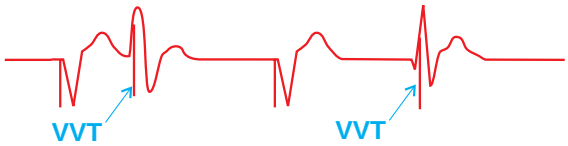
Temporary pacing at the AAT mode (30 bpm) when atrial sensing is properly adjusted

Temporary pacing at the AAT mode (30 bpm) with undersensing of the atrial channel



This could be asynchronous pacing, a pseudofusion beat (sensing has not yet occurred) or a triggered response (sensing has already occurred)

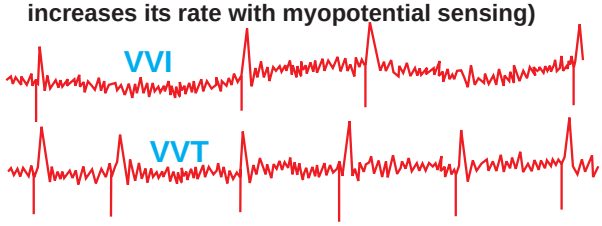




Triggered pacemaker modes are intended mostly for pacemaker diagnostic purposes :

1/ to facilitate identification of sensed events with pacing artifacts e.g. in high noise environment

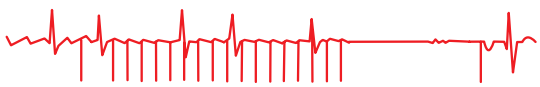
2/ to correct myopotential oversensing unresponsive to lowering sensitivity (the pacemaker then increases its rate with myopotential sensing)



3/ to correct oversensing from noisy leads, until lead replacement can be performed

4/ to show retrograde P waves and to measure the sensed signal in DDT mode

5/ to perform electrophysiologic studies and termination of tachycardias by chest wall stimulation (CWS) in pacemakers without these functions



The triggered modes can be used in Holter recordings in patients with suspected oversensing that cannot be demonstrated in the pacemaker clinic with telemetered markers. The triggered impulse represents a marker for the diagnosis and the timing of sensed signals.

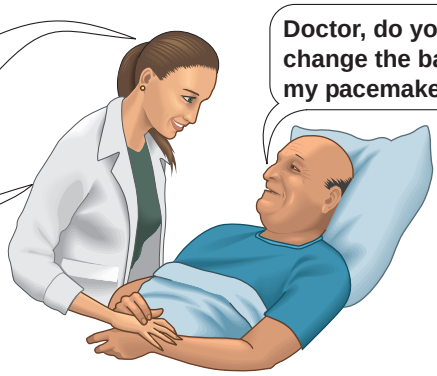
Abbreviations : CWS = chest wall stimulation: delivery of pacemaker stiumuli to the chest wall with an external pacemaker (painless procedure unable to capture the heart) to be sensed by an implanted pacemaker ; **LRI** = lower rate interval ; **VRP** = ventricular refractory period ; **DDT** mode = a triggered response occurs in the atrium upon atrial sensing and a triggered response also occurs in the ventricle upon ventricular sensing

BATTERY DEPLETION & END OF LIFE

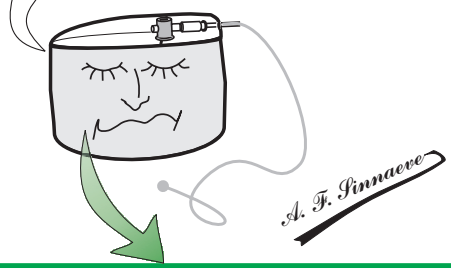
The battery of your pacemaker is almost depleted. The mode of the device is changed and its pacing rate remains low.

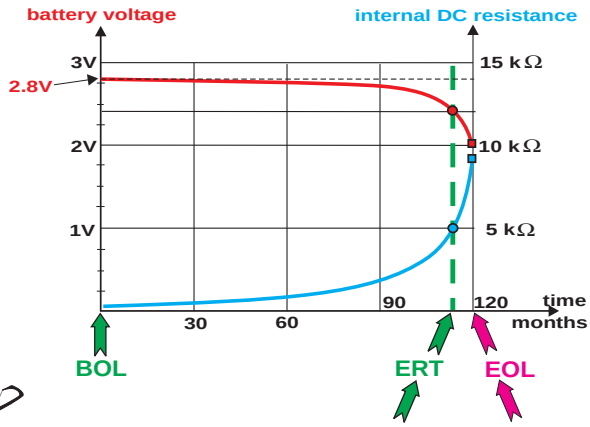
Doctor, do you have to change the batteries of my pacemaker ?

No, we have to replace the device, not just the battery ! We are taking you to the operating room.



I can predict the end of my life and I report it to the doctor by a diagnostic elective replacement indicator !
I do not want to reach the end-of-life point when my function will be erratic and may cause complications.





DIAGNOSTIC ELECTIVE REPLACEMENT INDICATORS

1. Percent or fixed decrease in the magnet rate; the free-running rate may also decrease according to design
2. Increase in pulse width duration in some pacemakers to compensate for a lower voltage output delivered to the heart.
3. Change to simpler pacing mode : DDDR to VVI, VVIR to VVI or VOO to reduce battery current drain and delay the time to end of life.

BOL = Beginning-Of-Life : when the pacemaker is new - battery voltage approx. 2.8V and battery impedance less than 1kΩ

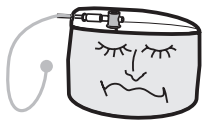
EOL = End-Of-Life : when the battery is depleted and the basic pacer functions not longer supported - battery voltage lower than approx. 2.1 - 2.4V and battery impedance higher than 5 - 10kΩ

ERT = Elective Replacement Time : generator replacement should be considered well in advance of end of life - battery voltage is reduced but still able to support basic or all pacer functions

ERI = Elective Replacement Indicator : battery voltage approx. 2.1 - 2.4V and battery impedance approx. 5 - 10kΩ

SPECIFIC VALUES OF EOL & ERI WILL VARY FROM MANUFACTURER TO MANUFACTURER

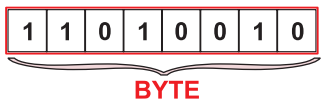
THE PACEMAKER AS A HOLTER RECORDER



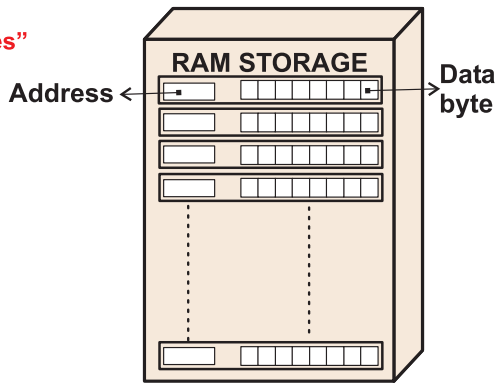
DECIMAL COUNTING FOR HUMANS	BINARY COUNTING FOR MACHINES
Ten digits : 0, 1, 2, 3, 4, 5, 6, 7, 8, 9	Only two digits : 0 and 1 called "bits"
$14 = 1.10^1 + 4.10^0$	$1110 = 1.2^3 + 1.2^2 + 1.2^1 + 0.2^0$
$= 10 + 4$	$= 8 + 4 + 2 + 0$

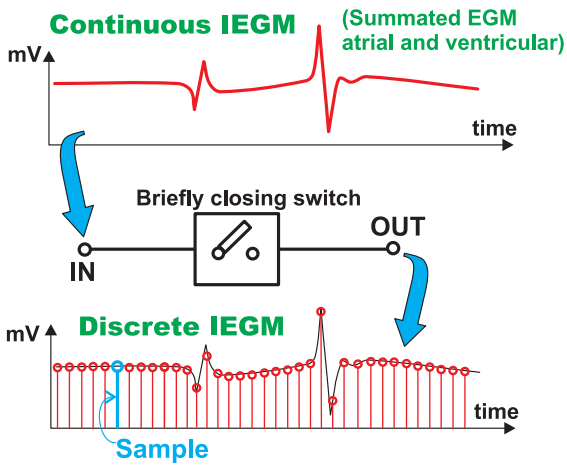
EQUIVALENT

A sequence of eight adjacent bits forms a "byte".



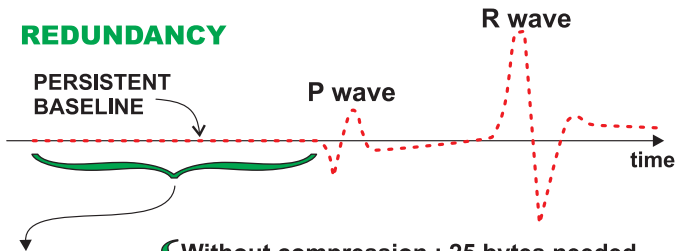
When information is read by the pacemaker and stored in its electronic memory, it is done byte-by-byte. Memory is usually measured in "kilobytes" (kB). One kilobyte = 1024 bytes.





The microprocessor cannot handle continuous signals. Hence, "sampling" is used to measure the signal repeatedly during a very brief instant, creating a set of discrete values or "samples". Sampling is usually performed at 128 or 256 samples per second.

The intracardiac electrogram (IEGM) is immediately stored in the RAM of the pacemaker. Each sample corresponds with one byte of data storage. Each byte is stored at a specific memory address for retrieval at a later time. A 128kB RAM includes 128 x 1024 = 131 072 bytes. When sampling at 256 samples/s, this RAM is sufficient for 131,072 / 256 = 512 s = 8.5 minutes of IEGM.



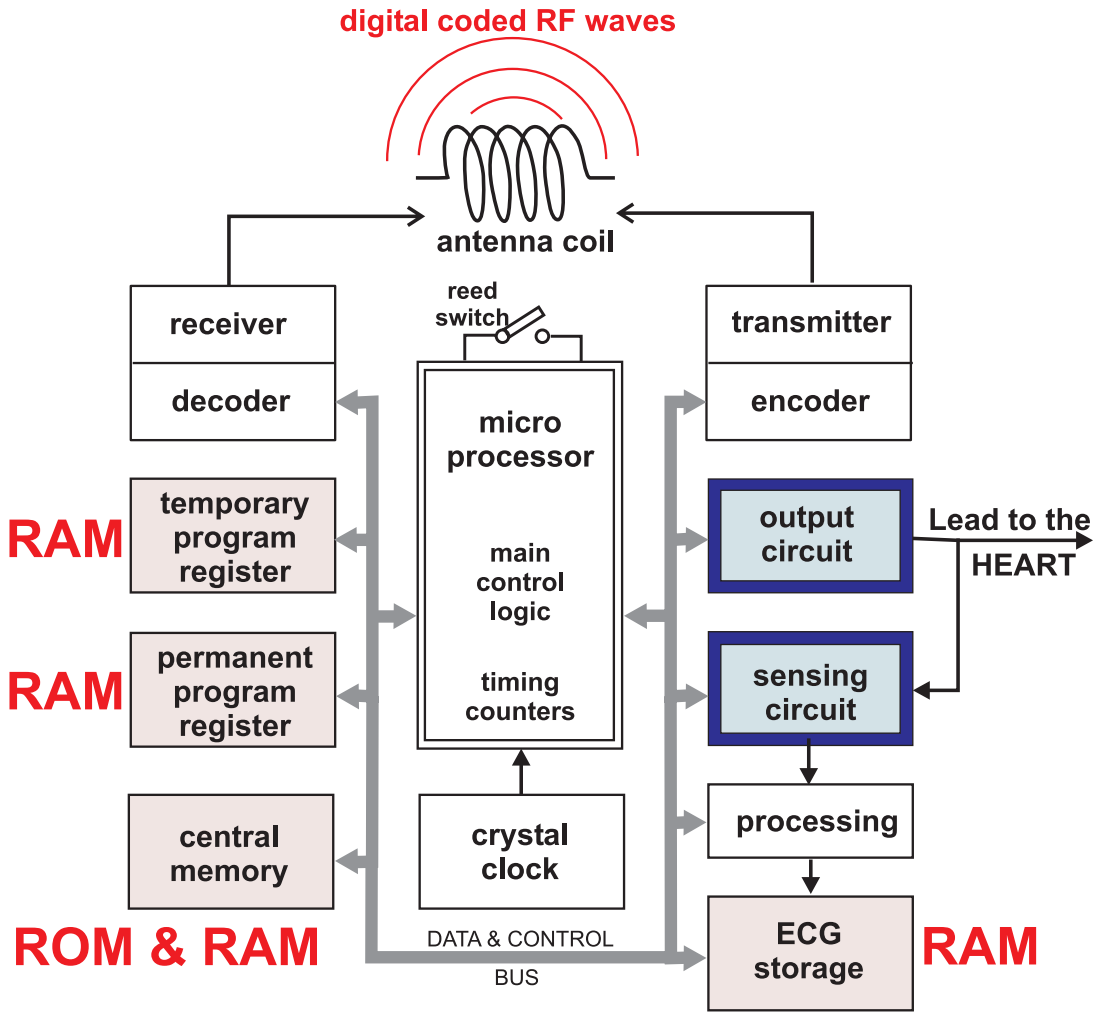
Compression algorithms reduce the number of bytes and increase the amount of IEGM that can be stored in the RAM of the pacemaker

REQUIREMENTS FOR 24-h RECORDING OF IEGM :
24 h/day x 60 min/h x 60 s/min = 86,400 s/day
128 samples/s x 1 byte/sample x 86,400 s/day = 11million bytes/day
Sampling at 128 samples/s requires a RAM of 11,000 kB

THE FUTURE : within 3 - 5 years ??

A. F. Sinnaeve

THE MEMORY OF A VVI PACEMAKER

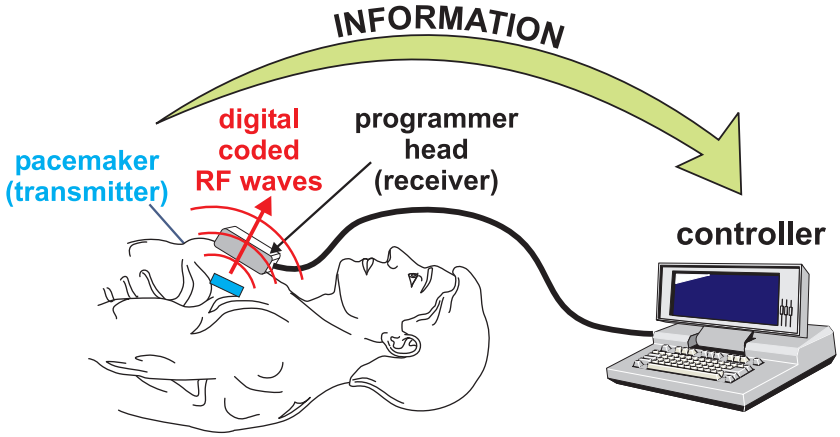


ROM = read only memory
(is installed by the manufacturer; cannot be modified by the physician via the programmer)

RAM = random access memory (read & write)
(content can be changed by measurements of the pace-maker or by the physician via the programmer)

A. F. Sinnaeve

THE CONCEPT OF TELEMETRY



DATA OBTAINABLE BY TELEMETRY

* **ADMINISTRATIVE DATA** (model, serial number, patient's name, date of implantation, indication for implantation)

* **PROGRAMMED DATA** (mode, rate, refractory period, hysteresis on/off, pulse amplitude & width, sensitivity)

* **MEASURED DATA** (rate, pulse amplitude, pulse current, pulse energy, pulse charge, lead impedance, battery impedance, battery voltage, battery current drain)

* **STORED DATA** (Holter function, rhythm histogram, ...)

* **MARKER SIGNALS** for ECG interpretation

* **INTRACARDIAC ELECTROGRAM**

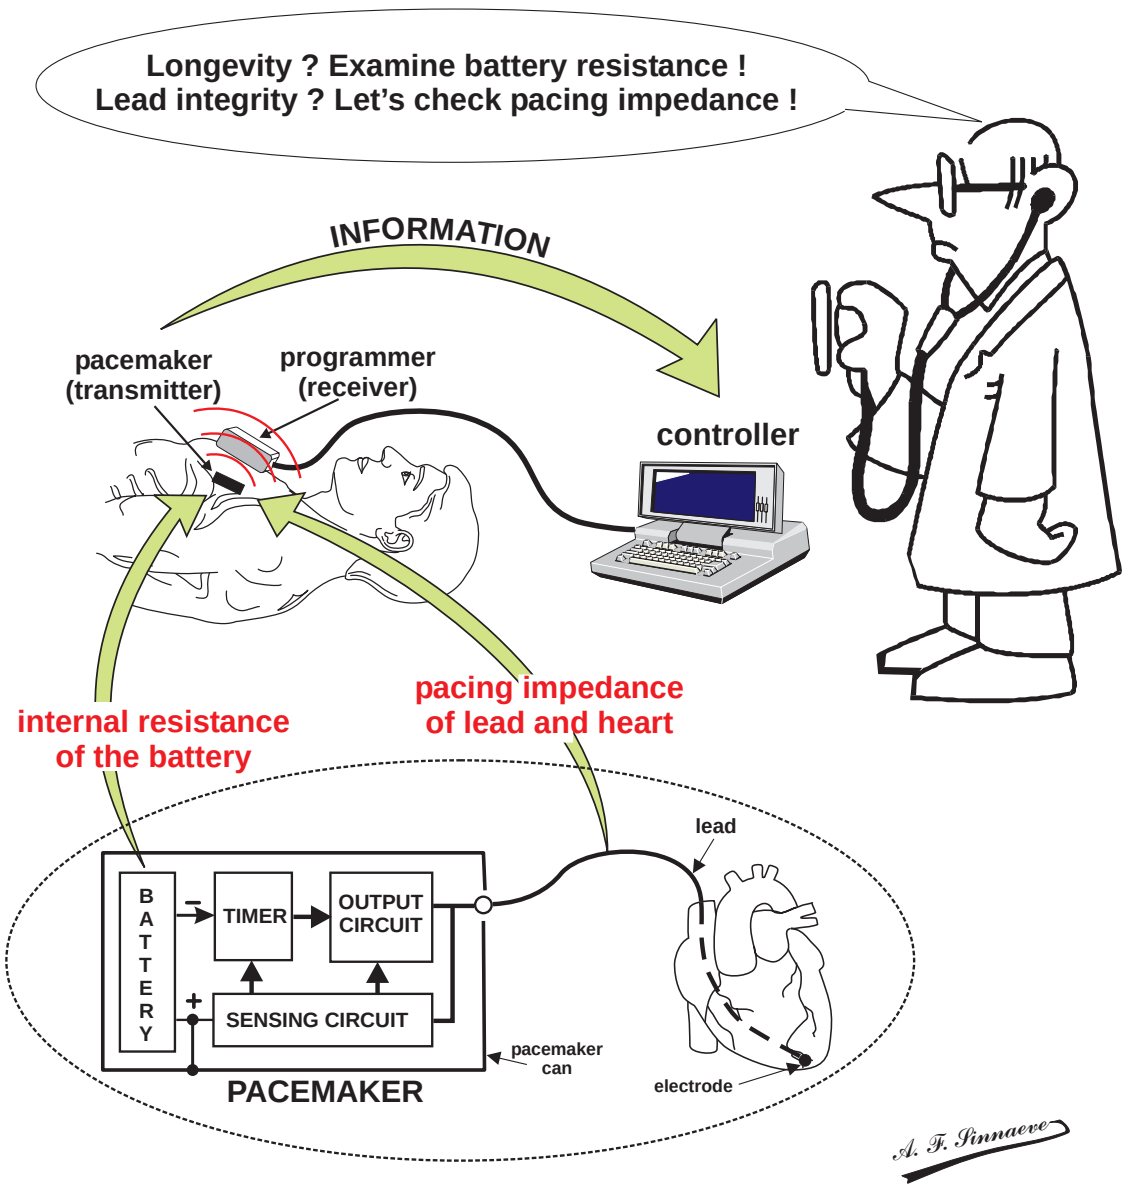
A. F. Sinnaeve

THE INTERROGATION

The guy has a pacemaker ! Let's interrogate him and his device. Make sure you use the correct programmer for his device and apply the programming head carefully over the pacemaker for telemetry. Press "Interrogate" and obtain the basic information.
You should get 4 lots of data. 1. Administrative data. 2. Programmed data. 3. Measured or real-time data. 4. Memorized data.
These print-outs will provide preliminary evidence that the pacemaker is working properly ! OK ?

Sir, I'll look at the administrative data first, so that we know the model, serial number and implantation data if nobody forgot to program that data into the pacemaker.
Then, I'll look at the programmed data to determine the basic parameters of the device.

MEASUREMENT OF RESISTANCE & IMPEDANCE BY TELEMETRY



THE MEMORIZED DATA

Advances in pacemaker technology have improved the memory function of pacemakers. The quantity of memorized data can be intimidating. Important memory functions include :

1. **% paced and sensed events in each chamber.**
2. **% of pacemaker events : As-Vs, As-Vp, Ap-Vs, Ap-Vp, VPC.**
3. **Histograms of various functions including heart rate with and without sensor activation, time and duration of automatic mode switching (and detected atrial rate).**
4. **Trends : display of periodic automatic recordings of lead impedance and intracardiac P and QRS amplitude.**
5. **Diagnosis of arrhythmias with marker chains and/or stored atrial and ventricular electrograms. This function can be automatic or patient-activated by placing a magnet or activator over the pacemaker.**

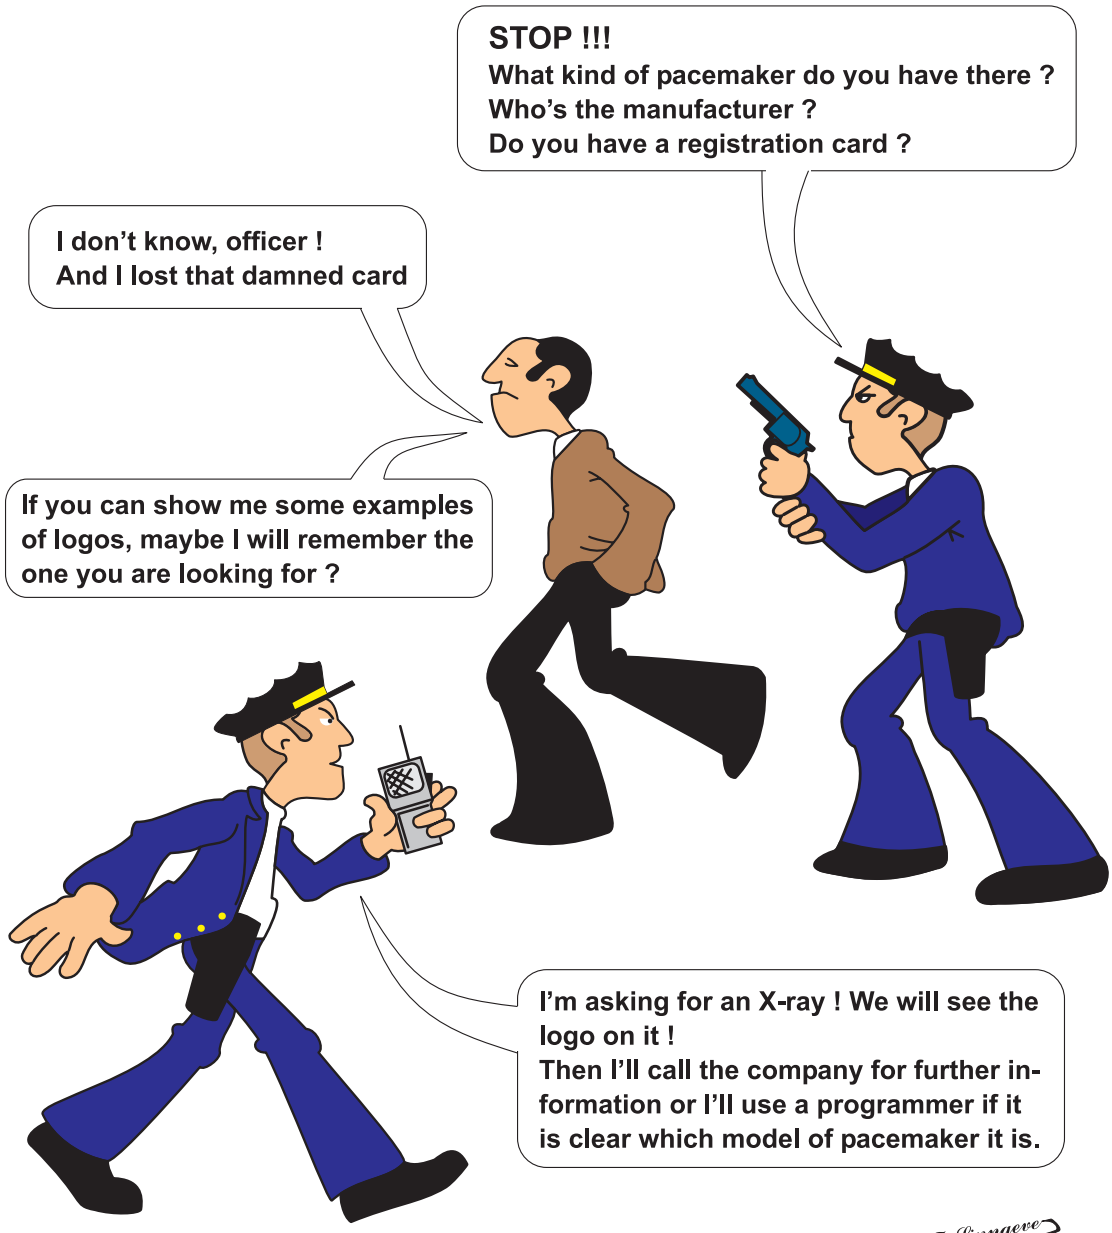
Abbreviatons : Ap = atrial paced event; As = atrial sensed event; Vp = ventricular paced event; Vs = ventricular sensed event; VPC = ventricular premature complex

THE MEASURED DATA

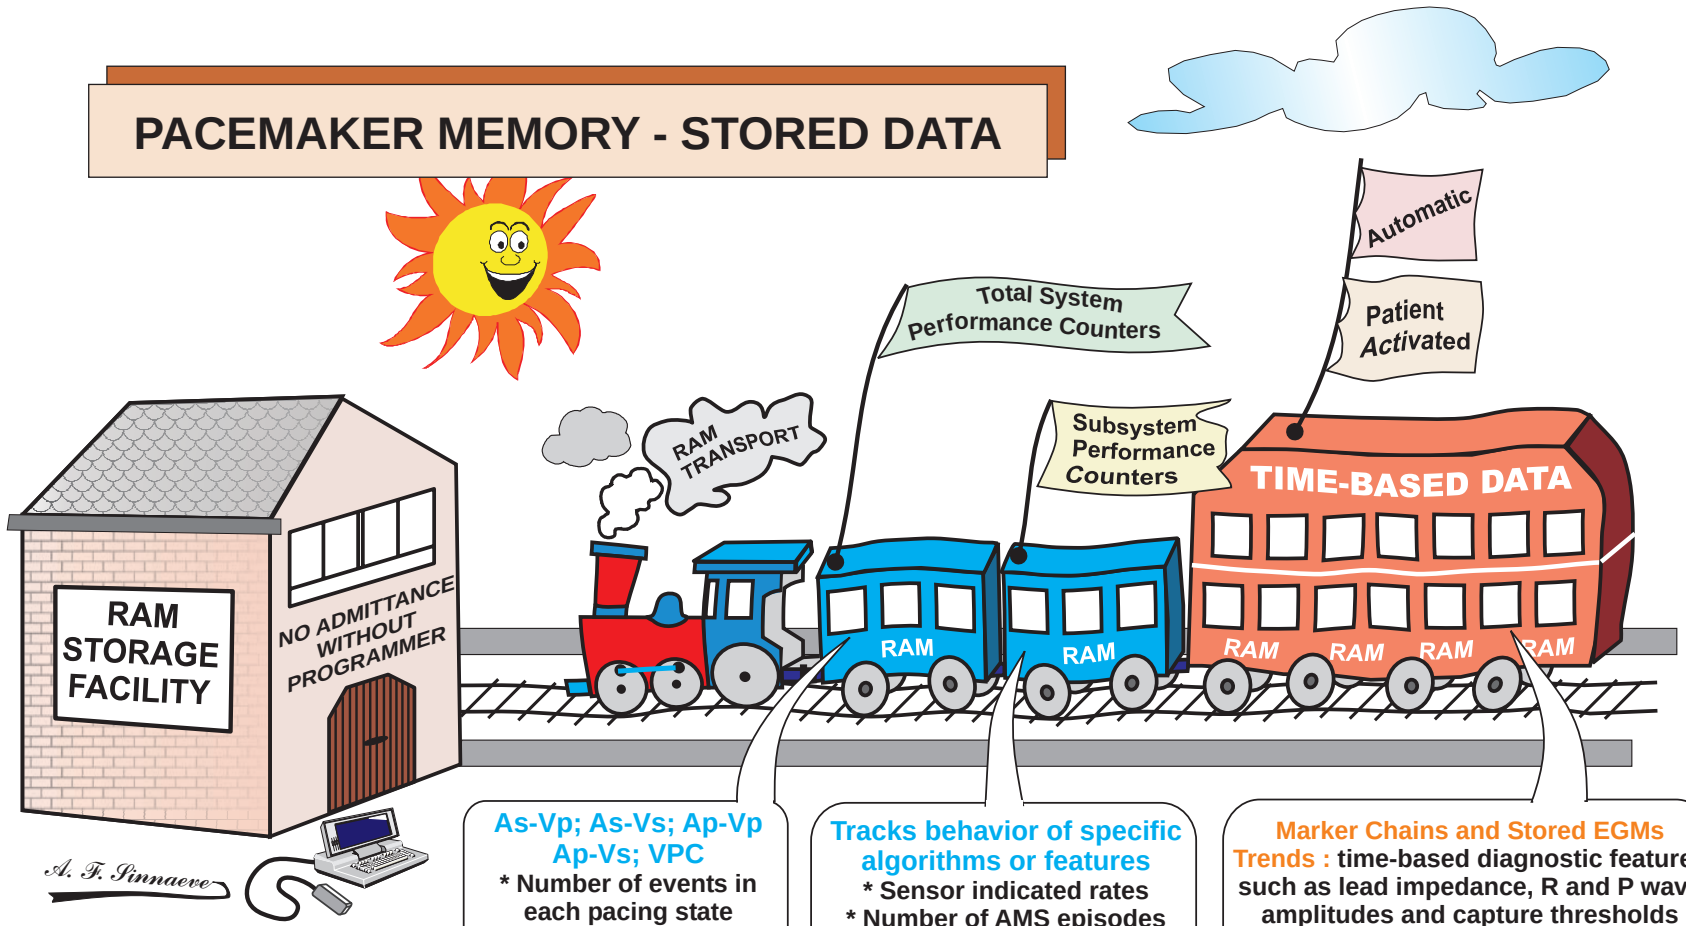
The measured data is real-time ! And the data of 2 channels (A and V) is displayed simultaneously. We have here information about :

1. The output - pacing rate in beats per minute (bpm)
   - pulse voltage amplitude in volts (V)
   - pulse duration in milliseconds (ms)
2. The battery - battery voltage in volts (V)
   - battery current drain in microamperes (μA)
   - battery impedance in ohms (Ω)
3. The leads - lead impedance in ohms (Ω)
   - lead configuration (bipolar/unipolar)

THE UNIDENTIFIED PACEMAKER



PACEMAKER MEMORY - STORED DATA



As-Vp; As-Vs; Ap-Vp Ap-Vs; VPC
* Number of events in each pacing state
* Rate distribution within each pacing state
* % paced in atrium and ventricle

Tracks behavior of specific algorithms or features
* Sensor indicated rates
* Number of AMS episodes (duration and atrial rate)
* Amount of time spent at maximum rate
* etc.

Marker Chains and Stored EGMs
Trends : time-based diagnostic features such as lead impedance, R and P wave amplitudes and capture thresholds often presented as graphs

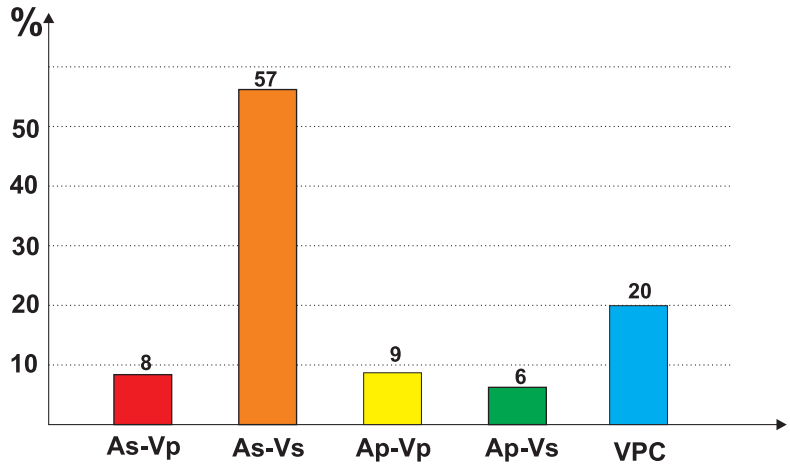
In system performance counters, time-based individual events are placed in the sequence of their occurrence !!!

Vocabulary :

As-Vp (= PV) = atrial sense-ventricular pace; As-Vs (= PR) = atrial sense - ventricular sense; Ap-Vp (= AV) = atrial pace-ventricular pace; Ap-Vs (= AR) = atrial pace-ventricular sense; VPC = ventricular premature complex; EGM = electrogram; RAM = random access memory; AMS = automatic mode switching

STORAGE OF PACING STATES

I can make a "short term histogram" for the last three-to-six days or a "long term histogram" containing data since the last programming session



(Ap-Vp) + (Ap-Vs) : total % of atrial paced events ;
- *** if this total is large, there is a lot of pacing at the basic rate**
- *** if this total is large, it suggests sick sinus syndrome and atrial incompetence**

(As-Vp) + (As-Vs) : total % of atrial sensed events ;
- *** if As-Vp is very large there is an AV block or the AV delay (AVI) is programmed too short**
- *** if As-Vs is large, the pacemaker functions on stand-by basis most of the time**

(As-Vs) + (Ap-Vs) : total % of sensed ventricular events
- *** if this total is large, there is a good spontaneous AV conduction**

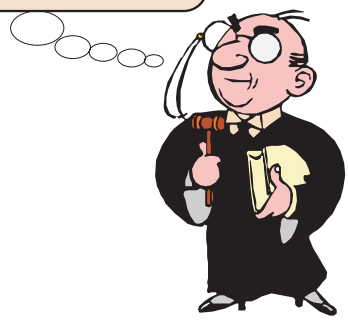
A. F. Simmaeve

(As-Vp) + (Ap-Vp) : total % of paced ventricular events

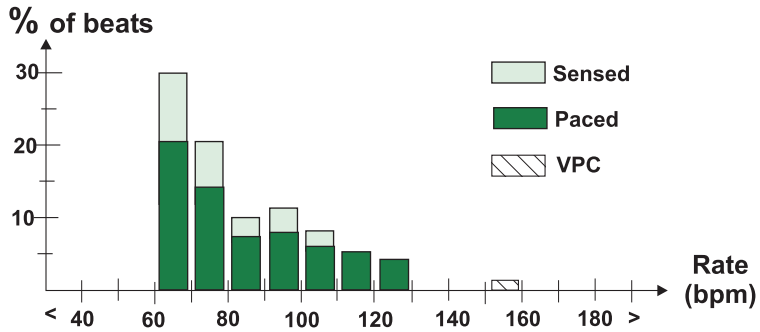
VPC : note that a VPC according to the pacemaker is not necessarily equal to a clinical PVC

Abbreviations :
As-Vp (= PV) = atrial sense-ventricular pace; As-Vs (= PR) = atrial sense-ventricular sense; Ap-Vp (= AV) = atrial pace-ventricular pace; Ap-Vs (= AR) = atrial pace-ventricular sense; VPC = ventricular premature complex; PVC = premature ventricular complex

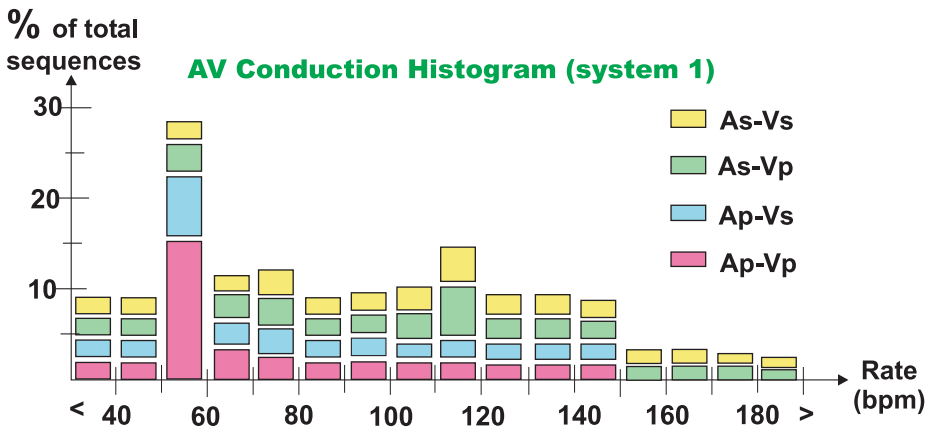
DO NOT RELY ON JUST ONE HISTOGRAM !
INTERPRET IT IN CONNECTION WITH OTHER DATA.



Ventricular Heart Rate Histogram



AV Conduction Histogram (system 1)



AV Conduction Table (system 2)

Rate (bpm)	As-Vp	As-Vs	Ap-Vp	Ap-Vs	VPC
30 - 54	45	0	9 546	0	0
55 - 69	308 978	79	2 974 366	1 322	0
70 - 89	298 459	1 504	621 788	1 908	6 968

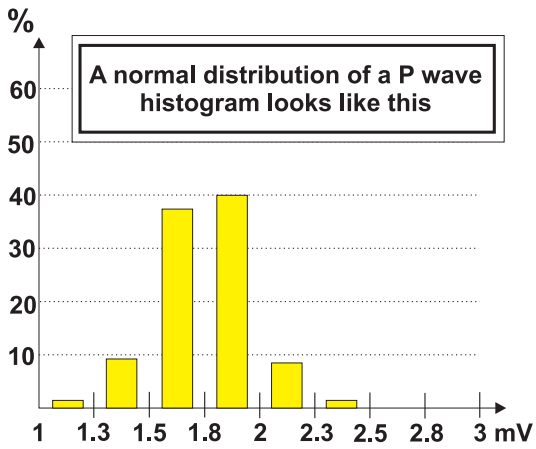
110 - 129	100	315	0	0	7 173
130 - 149	0	152	0	0	447
150 - 179	0	409	0	0	2 235
180 - 224	0	205	0	0	625
225 - 249	0	0	0	0	1
> 250	0	0	0	0	0
Total :	619 275	3 653	3 606 308	3 628	101 690

A. F. Pinnaeve

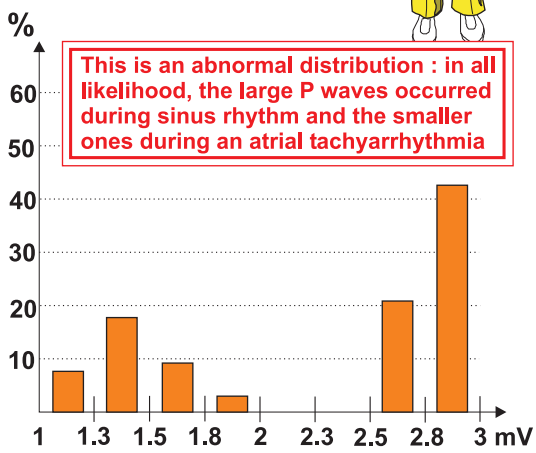
Abbreviations :
As-Vs (= PR) = atrial sense - ventricular sense; As-Vp (=PV)= atrial sense - ventricular pace; Ap-Vs (=AR) = atrial pace - ventricular sense; Ap-Vp (=AV) = atrial pace - ventricular pace; bpm = beats per minute; VPC = ventricular premature complex

P WAVE AMPLITUDE HISTOGRAM

The P wave histogram can be helpful for :
* Evaluation of the safety margin for atrial sensing
* Detection of lead displacement
* Detection of atrial arrhythmias
* Detection of interference
* Detection of near-field & far-field sensing



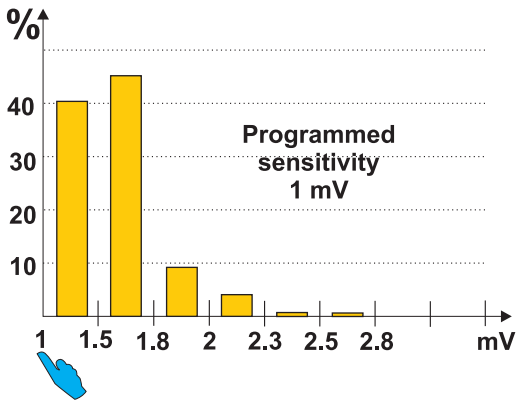
A normal distribution of a P wave histogram looks like this

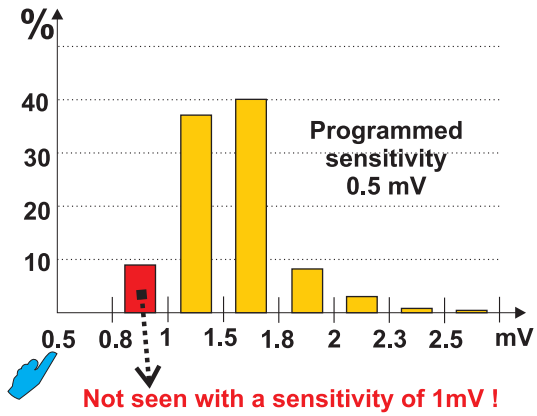


This is an abnormal distribution : in all likelihood, the large P waves occurred during sinus rhythm and the smaller ones during an atrial tachyarrhythmia

Evaluation of the safety margin for atrial sensing. Signal vs. programmed sensitivity.

The histogram is limited on its lower side by the programmed sensitivity !!!
Programming different sensitivities may unmask undersensing



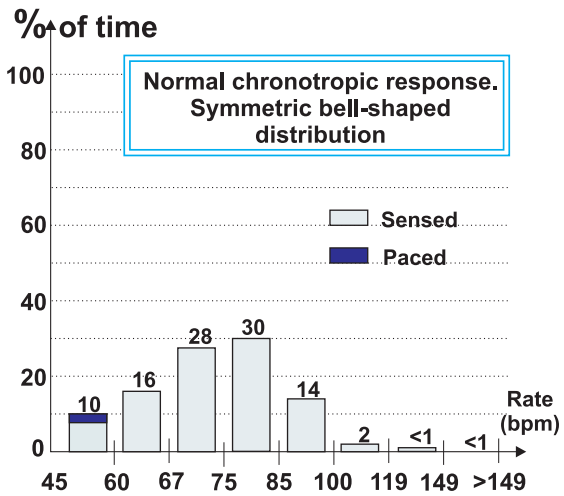


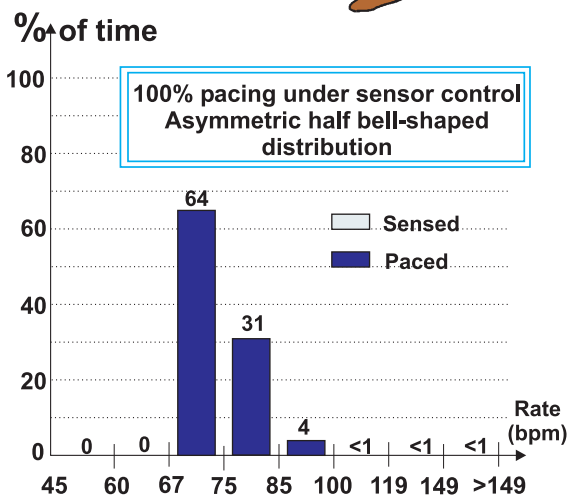
Not seen with a sensitivity of 1mV !

A. F. Sinnaeve

The pacemaker automatically collects the data !
These histograms are very useful for the evaluation of the condition of the patient, the performance of the total system and the adjustment of the sensor characteristics.

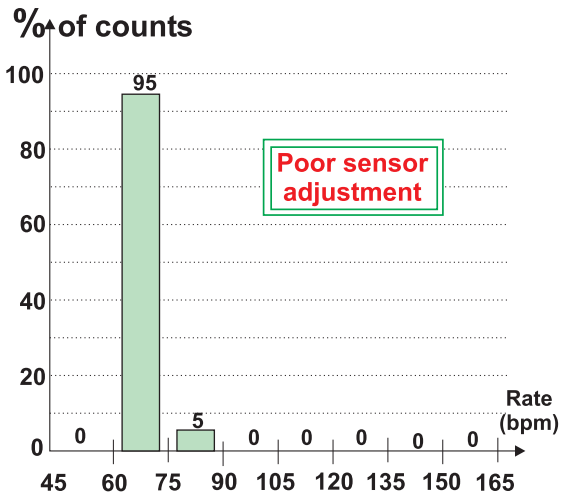
HEART RATE HISTOGRAM

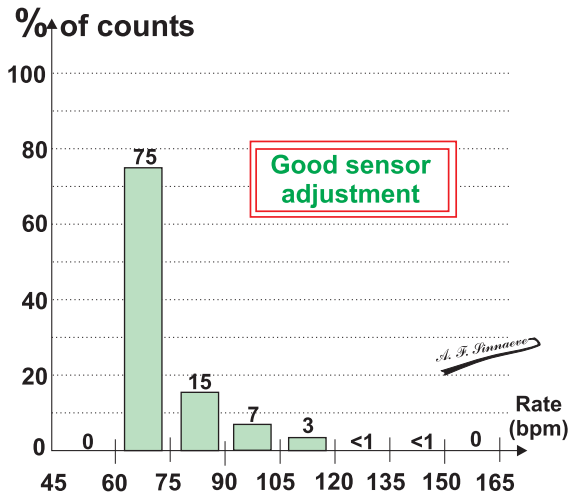




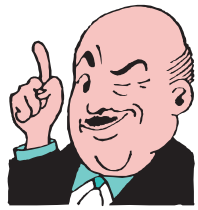
SENSOR INDICATED RATE HISTOGRAM

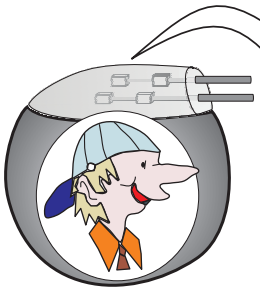
Such histograms are useful to determine whether the sensor is adjusted properly !
The histogram indicates the rate the pacemaker would be pacing if the patient were 100% paced.
If the spontaneous rate is faster than the sensor indicated rate and inhibits the pacemaker, this histogram is an underestimation of the actual heart rate.





BEWARE OF STORED DATA IN THE PACEMAKER MEMORY

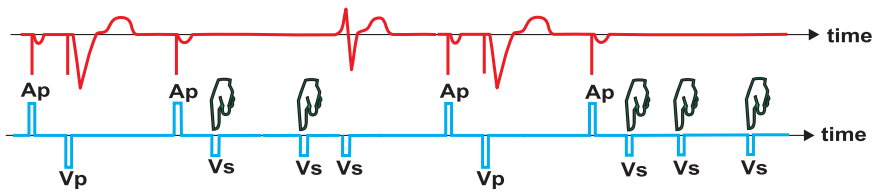




I am a very smart pacemaker because I can tell precisely when stimuli are delivered to the atrial and ventricular channels. I also know exactly when I sense activity from the atrial and ventricular channels. I relay this information faithfully to the marker channel for visual proof.
Sorry, but I am not smart enough to know whether a stimulus actually captures the heart and I have no idea whatsoever whether a sensed event is physiologic or some undesirable potential.

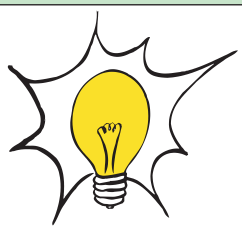
The pacemaker is right ! It's really up to us to determine the presence of capture and the precise nature of the sensed events.
You know that the simultaneous display of markers and real-time electrograms by telemetry can pinpoint the exact nature of a sensed event which is impossible with markers alone.
However, the electrogram has limitations because it cannot tell us whether capture has occurred.

A simultaneously recorded electrogram might reveal the true nature of the oversensed signals : false signals from a defective lead? myopotentials? electromagnetic interference? etc.



LIMITATIONS OF STORED DATA :

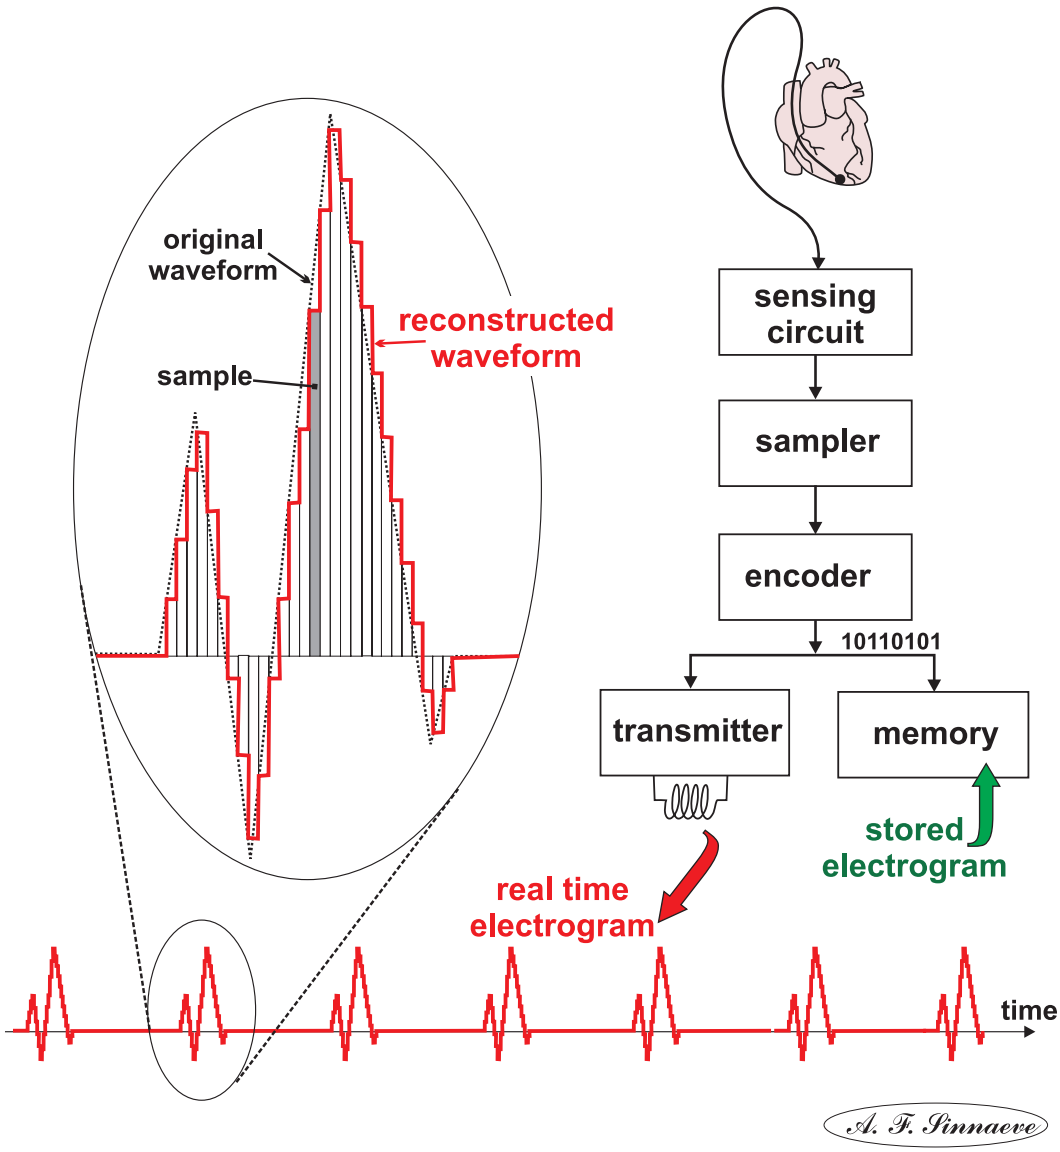
* Many VPCs at a low rate may indicate atrial undersensing with intact AV conduction
* A large percentage of As-Vp complexes may indicate AV block or an AV interval programmed too short
* A majority of Ap-Vp or Ap-Vs complexes do not allow the diagnosis of atrial chronotropic incompetence without knowing the actual rates achieved in each pacing state



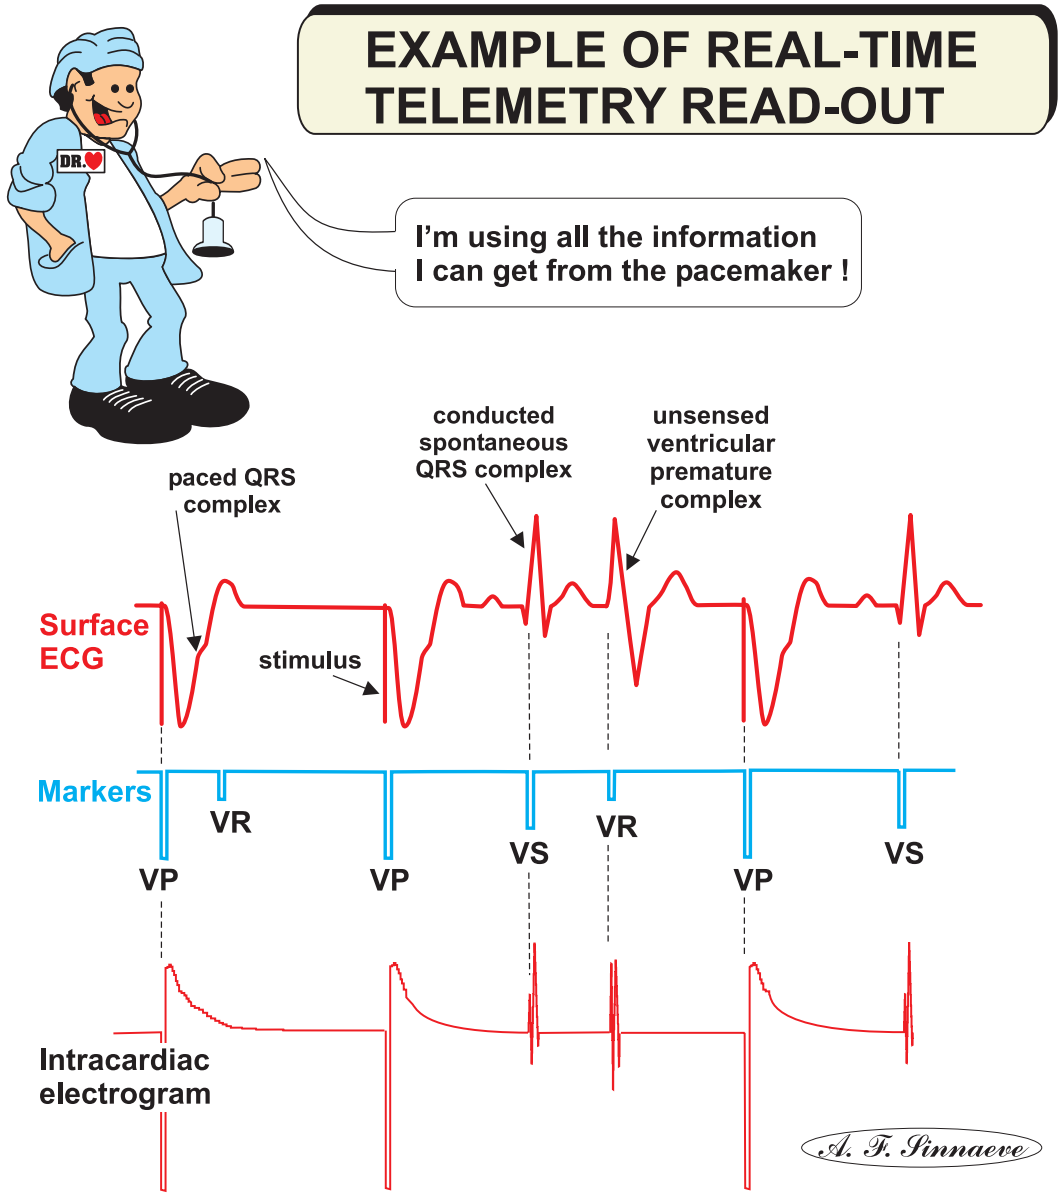
A true pacemaker problem could be missed if one relies only on the counters. However, counter data is useful when one is absolutely certain that the pacemaker system is functioning normally.

A. F. Sinnaeve

TELEMETERED VENTRICULAR ELECTROGRAM



EXAMPLE OF REAL-TIME TELEMETRY READ-OUT



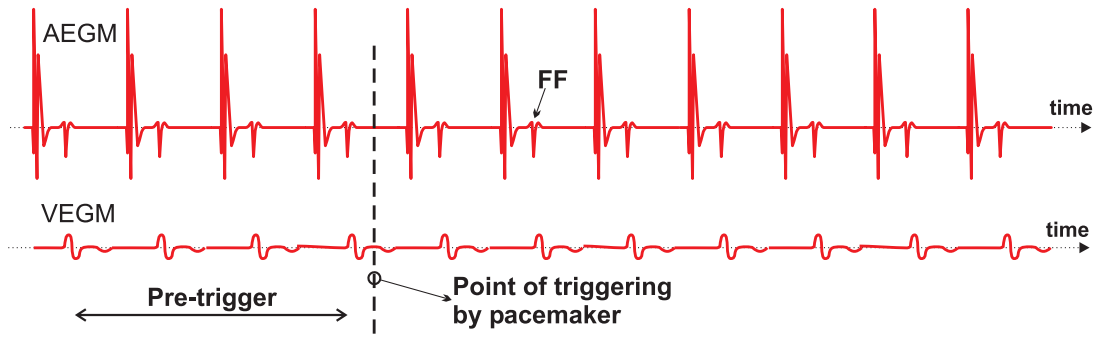
Abbreviations : VP = ventricular pace ; VS = ventricular sense ; VR = ventricular sense in the refractory period

STORED ELECTROGRAMS AN ASSISTANCE FOR DIAGNOSIS PART 1

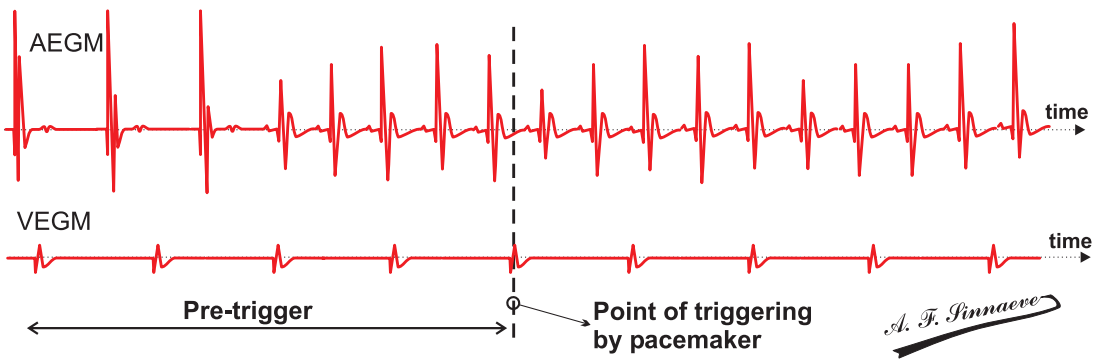
THE GOLD STANDARD

1. Separate channels for atrial and ventricular EGMs of sufficient resolution and duration.
2. An EGM scale to quantify signal amplitude and thus discriminate between small far-field signals, intrinsic beats, and giant false signals generated by lead disruption.
3. Onset and termination data : a programmable number of cardiac cycles before arrhythmia onset (pre-trigger EGM) and some cycles after arrhythmia termination to distinguish between correct detection of the onset of a new episode such as immediate or early recurrence of AT and intermittent signal dropout.
4. Marker annotations and intervals to facilitate understanding why and how the pacemaker detected and classified an event. An additional marker (e.g. arrow, line) should indicate the exact moment when arrhythmia detection criteria were fulfilled.

VA CROSSTALK - Sinus rhythm labeled SVT by the pacemaker. Note the far-field R wave in the atrial electrogram sensed by the atrial channel



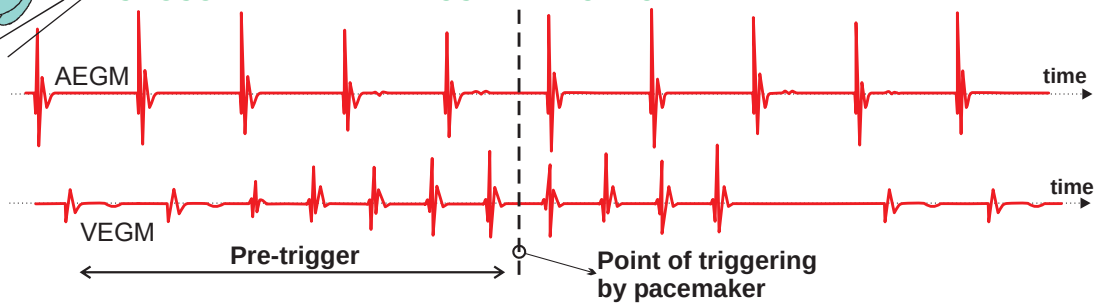
INITIATION OF ATRIAL FLUTTER



Abbreviations : AEGM = atrial electrogram ; AT = atrial tachycardia ; EGM = electrogram ; FF = far-field R wave ; SVT = supraventricular tachycardia ; VEGM = ventricular electrogram

STORED ELECTROGRAMS AN ASSISTANCE FOR DIAGNOSIS PART 2

UNSUSTAINED VENTRICULAR TACHYCARDIA



ATRIAL FIBRILLATION RECORDED BY MAGNET ACTIVATION OVER THE PM WHEN THE PATIENT WAS SYMPTOMATIC

ADVANTAGES OF STORED EGMs

1. Markers without simultaneous EGM recordings are of limited value in diagnosis
2. The many pitfalls must be recognized. The PM diagnosis may be incorrect. However, visual inspection of EGMs and markers guarantees the right diagnosis in almost 100% of cases.
3. Explanation of symptoms by patient's triggered recordings.
4. EGM recordings permit fine-tune programming of the device.
5. Identify AT and VT onset mechanisms which may have therapeutic implications

LIMITATIONS OF DEVICES IN AT DIAGNOSIS

1. Intermittent atrial sensing : a single AT episode will be stored as multiple short episodes
2. Atrial undersensing : may cause the PM to make the false diagnosis of VT
3. Long blanking period will cause 2 : 1 undersensing of atrial flutter
4. Far-field R wave oversensing causes false diagnosis of AT by PM

FACTORS INFLUENCING AT DETECTION

1. The detection algorithm of the PM
2. The signal quality and the programmed sensitivity
3. Timing cycles : blanking periods

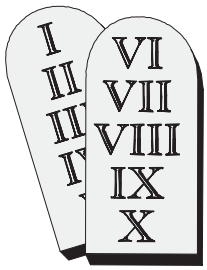
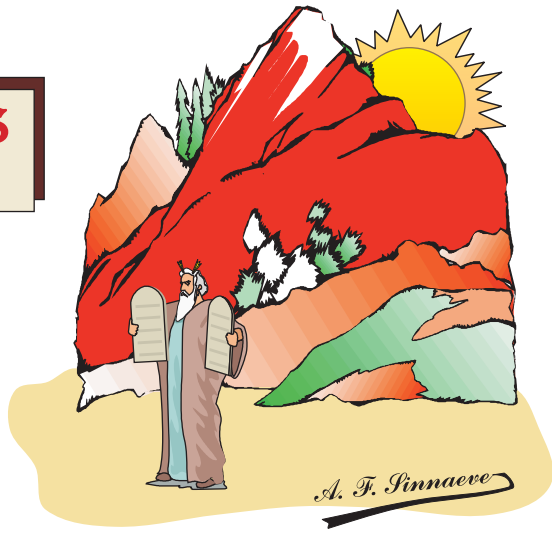
"All comprehension of pacemaker electrocardiography depends on the interpretation of pacemaker timing cycles"

SEYMOUR FURMAN MD, pioneer in cardiac pacing

THE 10 COMMANDMENTS OF PACEMAKER CARE





1. Thou shalt take long rhythm strips with markers and electrograms and thou shalt be rewarded with correct diagnosis.
2. Ignore the value of the 12-lead paced ECG at your own peril.
3. Know the timing cycles and you will know the pacemaker.
4. The purpose of antibradycardia pacing is not simply to treat bradycardia but to restore the quality-of-life.
5. Do not attribute a patient's symptoms to old age before you exclude a reversible cause such as pacemaker syndrome.
6. Leaving a pacemaker at factory settings (out-of-the-box parameters) without programming is a sin ! Like drug therapy, there is a pacemaker prescription for the individual patient and it should be changed according to circumstances.
7. Make every effort to conserve battery life and provide an appropriate safety margin by carefully programming voltage output and pulse duration.
8. The optimal AV delay cannot be predicted in the individual patient
9. You shall live in eternal damnation if you fail to test for retrograde ventriculoatrial conduction and program the pacemaker accordingly.
10. You will be banished into the wilderness for ever, if you fail to keep meticulous records of pacemaker follow-up.

Text: overview of cardiac pacemakers

Implantation

A pacemaker (also known as a pulse generator) is a device that delivers electrical stimuli over leads with electrodes in contact with the heart. The lithium–iodine battery is sealed in a titanium can and provides electricity through a chemical reaction. The pacemaker is like a little computer. The epoxy connector block on top of the pacemaker makes the connection from lead to pacemaker. The lead is an insulated wire. There are two types of leads: bipolar with the two electrodes embedded inside the heart; and unipolar with one electrode inside the heart and the other electrode being the pacemaker can. Both types are widely used. In both types, the tip electrode is virtually always the negative pole or cathode. Virtually all pacemakers are implanted intravenously under local anesthesia using either the cephalic vein exposed by surgery or percutaneous puncture of the subclavian vein. The leads are passed to the right side of the heart under X-ray vision (fluoroscopy). More recently for the treatment of heart failure, the left ventricle may be paced by insertion of a lead into a tributary of the coronary sinus, a venous structure on the epicardial surface of the left ventricle. The pacemaker pocket is fashioned over the pectoralis major muscle below the collar bone. True epicardial leads require thoracic surgery and are used only when there is no venous access.

Basic function

The pacing lead functions as a "two-way street" for the transmission of electricity to the heart for pacing as well as for the sensing of spontaneous cardiac electric activity from the heart to the pacemaker. The operative techniques and intraoperative measurements are straightforward compared to the technical knowledge required to understand the electrophysiology of pacing and follow-up of patients for the best use of the important programmable functions. The function of an implanted pacemaker can be altered by means of a programmer, which is a type of dedicated desktop computer. A modern pacemaker lasts 7–10 years. When the battery is depleted, the entire pacemaker (excluding the leads) is replaced.

Power source

The lithium–iodine battery is the gold standard of pacemaker power sources and the only one presently used in pacemakers. The battery has a long shelf life and can be hermetically sealed to protect the electronic components of the pacemaker. In lithium–iodine batteries, lithium is the anode and iodine the cathode. When delivering electric current, this battery progressively develops a slow rise in internal resistance that can be measured by telemetry. The rising battery impedance causes a fairly linear drop in cell voltage translated by design into a gradual decline in the pacing rate reflecting the status of the battery. The battery retains a satisfactory voltage for 90% of its life. Battery capacity expressed in ampere-hours is the quantity that expresses the longevity of a lithium–iodine battery. A pacemaker generally holds a capacity between 0.8 and 2.5 Ah (ampere-hours).

The current drain from the battery (expressed in microamperes, μA) is used to produce the stimulus and to feed the various sensing, detection and "housekeeping" electronic circuits. The output voltage of a fresh cell is 2.8 V (volt). The cell voltage at the elective replacement point is 2.2–2.4 V. The pacemaker replacement time can be determined by measuring the pacemaker rate upon application of a magnet or the battery voltage and/or impedance by telemetry with the programmer.

Reminder: The pacemaker (or pacing) stimulus is also known as a spike, an artifact or an output pulse.

Caveat: Do not confuse cathode with anode! The terminology of the battery terminals appears different from that of the load. For the battery, the anode is the negative electrode where electrons are freed from lithium atoms and *positive* lithium ions are produced. In the battery the cathode is the positive terminal where free electrons rebind with iodine to form *negative* iodide ions. At the load, the cathode is the negative terminal and the anode is the positive

one. The connection of battery to circuit is simple: positive to positive and negative to negative. Remember that the anode of the battery or load is where the electrons leave. The cathode of both the battery and load is where the electrons enter. It is as simple as that! These are the universal definitions found in all good books about electricity and/or electronics. It is not true that the anode and cathode of the battery are reversed by convention. The only convention is that the electric current flows from positive to negative.

Rate or interval?

The pacemaker, design engineers, and medical staff all "think" in terms of intervals rather than rate. The term rate should not be used when defining timing cycles. Rate is a relatively simple designation during continuous pacing or continuous inhibition, but it is of little value and confusing if pacing and sensing alternate. Yet for ease of programming, manufacturers have expressed parameters in terms of rate rather than interval. Programmed rates may also be useful when communicating with the patient or anyone with little knowledge of pacing. The abbreviation b.p.m. refers to beats per minute of the intrinsic heart rate and p.p.m. refers to the paced rate. These abbreviations, however, are often used interchangeably.

Caveat: Peculiar rhythms are created by electrocardiograph (ECG) machines and Holter recorders functioning at an incorrect speed. In a Holter recording, intermittent slowing of the recording will cause a pseudotachycardia. The diagnosis is evident when the duration of the QRS and T waves are too narrow when compared to those recorded at normal speed. Conversely, a faster speed will cause pseudobradycardia, with excessively long atrioventricular (AV) delays or PR intervals as well as QRS complexes.

Single chamber pacemakers

A ventricular asynchronous (VOO) pacemaker generates stimuli with no relationship to the spontaneous rhythm. The VOO mode is labeled "fixed-rate" or asynchronous. The competitive stimuli will capture the ventricle only when they fall outside the absolute refractory period of the ventricle that follows spontaneous beats. The VOO mode is now obsolete and used only for testing purposes by applying a magnet over the pacemaker. Ventricular fibrillation induced by a competitive pacemaker stimulus falling in the ventricular vulnerable period (the R-on-T phenomenon) is very rare outside of circumstances such as myocardial ischemia or infarction, electrolyte abnormalities or autonomic imbalance. Indeed transtelephonic transmission of the electrocardiogram with a magnet over a pacemaker is quite safe.

A ventricular inhibited (VVI) pacemaker senses the intracardiac ventricular depolarization or electrogram which is recorded by measuring the potential (voltage) difference between the two electrodes (anode and cathode) used for pacing. A VVI pacemaker has an internal clock or lower rate timing cycle that begins with a paced (VP) or sensed ventricular event (VS). The initial portion of the cycle (after VP or VS) consists of the ventricular refractory period (*VRP*, usually 200–350 ms) during which the pacemaker cannot sense any signals. More specifically, any signal during the refractory period cannot initiate a new lower rate interval (*LRI*). Beyond the *VRP*, a sensed ventricular event inhibits the pacemaker and resets the *LRI* so that the timing clock returns to baseline. A new pacing cycle is reinitiated and if no event is sensed, the timing cycle ends with the release of a ventricular stimulus according to the *LRI*. The sensing function prevents the competition between pacemaker and intrinsic rhythm that is seen with VOO pacing. Hence, the old term "demand pacemaker" for a VVI pacemaker to describe the delivery of a stimulus when the spontaneous rate is less than the lower rate of the pacemaker.

Caveats:

1. When a patient presents with an ECG showing no pacemaker stimuli, the pacing function should be tested by the application of a pacemaker magnet, which converts any pacemaker to the fixed-rate or asynchronous mode (VVI to VOO). One should refrain from performing carotid sinus massage (a vagal reflex producing sinus node slowing and AV block) in this situation because it may cause prolonged bradycardia resulting in the delivery of pacemaker stimuli that may or may not be capable of capture. It is safer first to establish effective pacing with magnet application.
2. The stimulus-to-stimulus interval (automatic interval) is usually equal to the escape interval, which is measured electronically from the time of intracardiac sensing to the succeeding stimulus. In practice, the escape interval is measured from the onset of the sensed QRS complex in the surface ECG. The escape interval measured in this way must necessarily be longer than the electronic escape interval because intracardiac sensing takes place a finite time after the onset of the surface ECG. Thus, if the QRS complex is wide and intracardiac sensing occurs 90 ms from the beginning of the surface ECG, the measured escape interval (with calipers) will be 90 ms longer than the programmed automatic interval.

Hysteresis

In hysteresis the electronic escape interval is longer than the automatic interval. Its purpose is to maintain sinus rhythm and AV synchrony for as long as possible at a spontaneous rate lower (e.g. 50 b.p.m.) than the automatic rate of the pacemaker (e.g. 70 p.p.m.). Thus when the spontaneous rate drops below 50 b.p.m., the pacemaker will take over at 70 p.p.m. It will continue to pace at 70 p.p.m. until the spontaneous rate exceeds the automatic rate, i.e. when the spontaneous QRS complex occurs within the 857 ms automatic interval.

Caveat: Do not misinterpret hysteresis for oversensing with pauses.

Symbolic representation of pacemaker events and basic measurements

Symbols are as follows: AS (P), atrial sensed event; AP (A), atrial paced event; VS (R), ventricular sensed event; VP (V), ventricular paced event; AR, atrial event sensed in the pacemaker refractory period; VR, ventricular event sensed in the ventricular refractory period. The second letter may be a capital or lower case. Note that in the designation using a single capital letter for an event (P, A, V, R), AR represents an AV interval (atrial pacing, ventricular sensing) and should not be confused with an atrial sensed event in the refractory period in the other designation (AR or Ar). Some devices depict a ventricular premature complex as a VPC or PVC. The refractory period is defined below. The intervals between events are measured by electronic calipers.

Timing cycles are expressed in milliseconds (ms): 1 s =1000 ms.

The 60 000 rule is useful in converting rate to intervals:

60 000/heart rate = interval in milliseconds;

60 000/interval in milliseconds = heart rate.

A pacemaker rate of 70 p.p.m. gives an interval of 857 ms.

Other single chamber pacemakers

A ventricular triggered (VVT) pacemaker releases a ventricular stimulus immediately upon sensing, which is the opposite of inhibition with the VVI mode. The VVT mode requires three timing intervals: *LRI* and *VRP* similarly to the VVI mode, but additionally it needs an upper rate interval to limit the maximum paced ventricular rate in response to ventricular sensing of rapidly occurring potentials. Upon sensing a QRS complex the pacemaker immediately discharges a stimulus (within it) in the absolute refractory period of the ventricular myocardium. The VVT mode ensures stimulation rather than inhibition whenever the pacemaker senses signals other than the QRS complex. The triggered mode is now rarely used as a primary pacing mode, but it was useful in the early days when VVI pacemakers were highly susceptible to external interference and the VVT mode was used to prevent inhibition.

An atrial inhibited (AAI) pacemaker is identical to the VVI mode except that it paces and senses in the atrium. It requires a higher sensitivity because the atrial electrogram is smaller than the ventricular one. The pacemaker refractory period (during which the *LRI* cannot be initiated) should be > 400 ms to prevent sensing of the conducted QRS complex as a far-field event in the atrial electrogram. Sensing of the far-field QRS complex by an AAI pacemaker (especially a more sensitive unipolar system) will cause slowing of the pacing rate because the sensed event (though not originating from the atrium itself) resets the *LRI*. An AAI pacemaker may be considered in patients with sick sinus syndrome with normal AV conduction. The subsequent development of AV block in carefully selected patients is < 2% per year. The advantages of AAI pacing are related to the preservation of normal ventricular depolarization and cost effectiveness. This is in contrast to modes with pacing-induced ventricular depolarization that tend to produce long-term left ventricle (LV) dysfunction related to the cumulative duration of right ventricular (RV) pacing.

Reminder: An appropriately programmed AAI pacemaker senses the normal P wave, and occasionally retrograde P waves and ventricular premature beats. The latter may be sensed despite the absence of a ventricular lead because ventricular depolarization can generate a far-field QRS signal on the atrial electrogram, which may be detected by an AAI pacemaker and interpreted as an atrial signal. Sensed signals other than sinus P waves may create puzzling pauses.

The atrial asynchronous (AOO) and atrial triggered (AAT) modes work in the atrium and are functionally similar to their ventricular counterparts.

Basic electricity

Electrons flow from the negative terminal to the positive terminal of an electric circuit. In the early days, the concept of electron flow was not fully understood so scientists randomly decided that current in a conductor flowed from the positive terminal and into the negative terminal. It is still convention (and confusing to some) today to show current flowing in this direction (i.e. opposite to electron flow). Current is the amount of charge (electrons or other charged

particles) that flows through an electric circuit within a unit of time. Its unit is the ampere (A). The flow of water is a good analogy of electricity. Water flows through a pipe because of water pressure. Voltage is the potential difference that controls the flow of electrons through an electric circuit. Current flows from a site of high potential to a low one. The basic unit of electric potential and voltage is the volt (V). The electrons in a pacemaker circuit come from the battery. Thus, voltage is the force behind the electrons and current is a measure of how many electrons are flowing per unit of time. Resistance or impedance is a measure of the opposition to the flow of electrons. Resistance limits the current that flows through a circuit for a particular applied voltage. The unit of resistance is the ohm (Ω).

Current (I), voltage (V) and resistance (R) are related by Ohm's law: $V = I \times R$. According to Ohm's law an increase in the pressure (voltage) must cause an increase in the flow (current) if the resistance remains the same. Increasing the resistance while keeping the voltage the same, decreases the current (flow).

The battery supplies the voltage that creates the flow (current) in a circuit with a given load or resistance. The battery capacity expresses "how long the battery will last while providing a current of 1 A." It is measured in ampere-hour (Ah). So a battery with a capacity of 1000 mAh would last for 1 h in a 1 A circuit. (1000 mAh is 1 A for 1 h). A lithium–iodine battery with a capacity of 2 Ah in a pacemaker circuit with a current drain of 25 μA (= 0.000 025 A) will last for 2 Ah ÷ 0.000 025 A = 80 000 h or approximately 3333 days = approximately 9 years.

Chronic pacing threshold and safety margin

The pacing threshold is the minimum "electrical activity" that causes consistent pacing outside the myocardial refractory period of the heart. In practice the pacing threshold is determined in terms of volts (V) and pulse duration. Every effort should be made at the time of implantation to obtain a pacing threshold as low as possible because its initial value may ultimately determine the threshold at maturity and hence the voltage and pulse duration required for safe long-term pacing. Local steroid elution attenuates the increase of pacing threshold during lead maturation and maintains low pacing thresholds during follow-up. Steroid elution has made the implantation of high-efficiency pacing leads with a small surface of 1.2 mm^2 feasible. Steroid-eluting leads are associated with remarkably low pacing threshold by virtue of their effect on the electrode–myocardial interface and tissue reaction. About 8 weeks after implantation the pacing threshold has usually stabilized and attained its chronic value. The output voltage and pulse duration of the pacemaker should then be programmed to maintain consistent long-term capture with an adequate margin of safety and maximal conservation of battery capacity. The capture threshold can vary during the course of a normal day and according to metabolic and pharmacological factors. Consequently it is important to provide protection for threshold fluctuations by a safety margin in terms of the pacemaker output.

In practice, the safety margin is determined in terms of volts and not pulse duration. The general recommendation is a voltage safety margin of 2 (or 100%). The output voltage of the pacemaker should be double the chronic voltage threshold at the same pulse duration. Voltage safety margin = output voltage/threshold voltage = 2:1 at an identical pulse duration. This value is acceptable in pacemakers without automatic adjustment of the output. However, the concept of a 2:1 safety margin has been challenged in view of data gathered by systems capable of automatic determination of the pacing threshold and adjustment of the output pulse. This experience has shown that for a few patients a safety margin of 2:1 may not be sufficient. Indeed, some physicians program a larger safety margin in pacemaker-dependent patients.

The relationship of voltage and pulse duration at threshold and at any time afterwards is not linear and is represented by the *strength–duration curve*. A shorter pulse duration requires a higher voltage to attain the pacing threshold. The strength–duration curve is steep with a short pulse duration and becomes essentially flat at a pulse duration of > 2 ms, a point which is called the rheobase. The curve shifts to the right as the chronic pacing threshold becomes established. Although the terms rheobase and chronaxie are used to describe the strength–duration curve, they are rarely used in the routine follow-up of pacemaker patients.

Important reminders:

1. At a fixed voltage, increasing the pulse duration from 0.1 to 0.2 ms may not necessarily yield a voltage safety margin of 2 or 100% despite the steepness of the strength–duration curve (on the left) for short pulse durations.
2. At a fixed voltage, tripling the pulse duration (not starting beyond 0.2 ms) will provide an adequate voltage safety margin based on the configuration of the strength–duration curve. Thus, a threshold of 2.5 V at 0.2 ms permits a programmed "chronic" output of 2.5 V at 0.6 ms for a voltage safety margin of 2.
3. When the pulse duration is ≥ 0.3 ms, tripling the pulse duration when keeping the voltage con-

stant may not provide a voltage safety margin of 2 because of the less steep and eventually straight configuration of the strength–duration curve (on the right) at longer pulse durations.

4. The relatively flat configuration of the strength–duration curve from 0.5 to 1.5 ms indicates that an increase in pulse duration in this range (keeping the voltage constant) will certainly not provide a voltage safety margin of 2.
5. Try to pace at a voltage lower than the traditional output of 5 V for greater efficiency and less wasted battery output.

Supernormal phase

The pacing threshold is lowest during a short period corresponding with the second half of the T wave. Consistent ventricular capture during this period and failure at other times, suggests that the pacemaker output is near threshold.

Considerations in pacing threshold

Let us consider some examples:

(a) threshold 2.5 v at 0.1 ms: program 2.5 v at 0.3 ms;
(b) threshold 2.5 v at 0.2 ms: program 2.5 v at 0.6 ms;
(c) threshold 2.5 v at 0.3 ms: program 5v at 0.3 ms;
(d) threshold 0.5 v at 0.2 ms: this is a very low pacing threshold; the pacemaker can be programmed at 0.5 V 0.6 ms but many would prefer going to 1 V at 0.4 or 0.5 ms, a setting that would still provide substantial battery conservation;
(e) threshold 5 V at 0.3 ms; increasing the pulse duration when the voltage is fixed at 5 V may not provide an adequate voltage margin. Increase the voltage output above 5 V if available in the pacemaker. If not, watch the patient carefully for bradycardia and asystole and decide whether to reposition the lead or implant a high output pulse generator providing a 10 V output.

Reminder: The chronic pacing thresholds are < 2.5 V at 0.5 ms pulse duration in > 95% patients with steroid-eluting leads. Patients with such leads rarely have a significant pacing threshold increase compared to those with nonsteroid leads. Consequently it does not make sense to leave the output (voltage and pulse duration) at nominal values. Appropriate programming of the pacemaker output can increase battery longevity. Furthermore, as the voltage of the lithium–iodine battery is 2.8 V, pacing is more efficient when performed close to that voltage (i.e. 2.5 V).

Caveats:

1. Always test the pacing threshold on deep respiration and coughing to detect an unstable electrode.
2. In the presence of left bundle branch block with a QRS complex resembling a paced ventricular beat, pseudocapture will be seen when the rate of the pacemaker stimulus is very close to that of the spontaneous rhythm and the stimulus falls just before the spontaneous QRS complex. This may resemble capture with latency (delayed interval from stimulus to ventricular activation). Long rhythm strips are needed for the diagnosis which will be obvious when the ventricular stimulus moves away from the QRS complex.
3. Beware of isoelectric paced QRS complexes that can mimic lack of capture. Look for the T wave because the presence of repolarization means that depolarization must have occurred.

Automatic determination of the pacing threshold

Some pacemakers have algorithms that periodically and automatically measure the ventricular capture threshold. The pacemaker recognizes the presence of capture, provides a stronger backup pulse if there is loss of capture and then adjusts the output automatically at a given value over the pacing threshold. Such periodic threshold measurements are memorized by the device and the threshold graph during the preceding follow-up period can be retrieved by interrogation of the pacemaker. Autocapture has increased patient safety but it is still unclear whether it increases battery longevity.

Some programmers are also designed to perform a pacing threshold test automatically at the time of follow-up and a printout of the procedure can be filed in the pacemaker chart.

Sensing

A pacemaker senses the potential difference between the two electrodes (anode and cathode) used for pacing. A bipolar system senses the potential difference between the two electrodes in the heart and requires recording of the bipolar electrogram to determine the characteristics of the signal available for sensing. The final bipolar electrogram depends on the electrograms registered at the two sites and the travel time of depolarization between the two electrodes. The bipolar electrogram can be easily recorded at the time of implantation with an ECG machine (leads applied to the two legs) by connecting the tip and proximal electrodes of the pacing lead to the free or loose right arm and left arm electrodes. Then, by using lead I on the ECG machine the bipolar electrogram can be recorded. This is because lead I provides the potential difference between the two arms and therefore the potential difference between the two intracardiac electrodes.

For a unipolar system (one electrode in the heart and the other on the pacemaker can), the unipolar

electrogram from the tip electrode closely resembles the available voltage for sensing. The contribution from the unipolar plate is usually so small that it can be neglected. The unipolar electrogram can be easily recorded by connecting the unipolar V lead of the ECG to the tip electrode while the other ECG electrodes are on the limbs in the usual way. The amplitude and slew rate of the electrogram must exceed the sensitivity of the pacemaker for reliable sensing. The ventricular signal often measures 6–15 mV, a range that exceeds the commonly programmed ventricular sensitivity of 2–3 mV. Occasionally a pacemaker senses the conducted QRS complex normally, but does not detect some ventricular extrasystoles because their electrogram (originating from a different site) is smaller, a situation not always correctable by reprogramming ventricular sensitivity. This is an accepted limitation of the sensing function of pacemakers. The atrial signal is smaller and should ideally exceed 2 mV. A signal with a gradual slope is more difficult to sense than one with a sharp upstroke. If the signal amplitude is large enough, the slew rate will always be sufficient and need not be measured. Determination of the slew rate is most useful when a signal is low or borderline (3–5 mV in the ventricle). On a long-term basis, the amplitude of the signal diminishes slightly but the slew rate may diminish further. These changes are usually of no clinical importance for sensing, except in the case of smaller signals.

The sensing circuit contains a bandpass filter that transmits some electrical frequencies more freely than others. A pacemaker filter is designed to pass all the signals of interest with negligible loss of amplitude and attenuate unwanted signals such as T waves or external interference. A typical bandpass filter favors the passage of signals with a frequency of 20–80 Hz in order to sense the wide range of QRS complexes and attenuates signals outside this range such as the T wave.

Caveat: The escape interval in a VVI pacemaker is measured from the onset of the surface QRS complex. In pacemakers with identical automatic and electronic escape intervals, the measured escape interval must of necessity be longer than the automatic interval by a value ranging from a few milliseconds to almost the entire duration of the QRS complex (with "late" sensing) depending on the temporal relationship of the intracardiac electrogram and the surface ECG. Do not confuse this with hysteresis.

Sensitivity

Programmability of sensitivity is important because the ideal electrode for sensing does not exist. Sensitivity is a measure of the minimal potential difference required between the terminals of a pacemaker to suppress its output. Looking above a wall is a good analogy of the numeral representation of sensitivity. The higher the wall, the less one will see above it. The lower the wall, the more one will see above it. The higher the numerical value of sensitivity, the less sensitive the pacemaker becomes. Thus, a setting of 6 mV can only sense a signal of 6 mV or greater and cannot sense signals smaller than 6 mV. On the other hand, a "higher" sensitivity of 1 mV will allow sensing of all signals of 1 mV or larger. The sensing threshold is determined by programming the pacing rate lower than the intrinsic rate while the sensitivity is gradually reduced (larger numerical value in mV) until failure to sense is observed. The sensing threshold is the largest possible numeric sensitivity value associated with regular sensing. As a rule, sensitivity should be programmed at a numerical value at least half the threshold value, e.g. from a sensing threshold of 8 mV one can program a sensitivity of 4 mV. Oversensing requires a decrease in sensitivity (increase in the numerical value). Most programmers now permit a fully automatic assessment of the signal amplitude at the time of follow-up. These measurements are taken from the sense amplifier and represent the signal amplitude after it has been processed.

Caveats:

1. Always test appropriate sensing, especially atrial sensing, with deep respiration to unmask significant fluctuations of the signal with respiration.
2. The absolute amplitude of the signal measured from the electrogram is only a rough approximation of the signal used for sensing. This is because the sensing circuit filters and processes the signal for sensing.

Polarity: unipolar vs. bipolar pacing and sensing

New lead technology and design have eliminated the previous advantage of unipolar leads. In practice, the long-term performance of unipolar and bipolar systems is similar. Bipolar leads by virtue of their greater signal-to-noise ratio (promoting greater protection against extraneous interference) allow the use of higher sensitivities. A high sensitivity is especially useful for atrial sensing, an important requirement of contemporary dual chamber pacemakers with the capability of diagnosing supraventricular tachyarrhythmias. This diagnosis permits a change in the pacing mode automatically to avoid rapid ventricular pacing. Bipolar leads are also associated

with less crosstalk in dual chamber pacemakers (ventricular sensing of the atrial stimulus). Bipolar leads are less sensitive than unipolar systems to external interference (myopotentials, etc.). The configuration of many pacemakers is programmable to either the unipolar or bipolar mode (provided they have bipolar leads) to correct certain pacemaker problems. In some devices when the circuit detects a high impedance (resistance) from a fracture in one of the electrodes, the pacemaker can automatically change from the bipolar to the unipolar mode of pacing using the intact electrode.

Reminders:

1. The tip electrode is almost always the cathode because the cathodal pacing threshold is lower. In a bipolar system the proximal (ring) electrode is the anode, and in a unipolar system a plate on the pacemaker can becomes the anode.
2. Contemporary pacemakers allow programming of unipolar or bipolar function in a variety of ways in individual channels: pacing only, sensing only, or both. A bipolar lead can be unipolarized by using either the tip or the ring electrode as the only intracardiac electrode for sensing and/or pacing.

Ventricular fusion and pseudofusion beats

Ventricular fusion beats occur when the ventricles are depolarized simultaneously by spontaneous and pacemaker-induced activity. A ventricular fusion beat can exhibit various configurations depending on the relative contributions of the two foci involved in ventricular activation. A ventricular fusion beat is often more narrow than a pure ventricular paced beat. Fusion therefore occurs in the heart itself.

Ventricular pseudofusion beats consist of the superimposition of an ineffectual ventricular stimulus on a surface QRS complex originating from a single focus and represent a normal manifestation of VVI pacing. A VVI pacemaker obviously does not sense the surface QRS complex. Rather, it senses the intracardiac ventricular electrogram registered between the two pacing electrodes. A substantial portion of the *surface* QRS complex can be inscribed before the *intracardiac* electrogram generates the required voltage (according to the programmed sensitivity) to inhibit the ventricular channel of a VVI pacemaker. Thus a VVI pacemaker can deliver a ventricular stimulus within the spontaneous QRS complex before the device has the opportunity to sense the "delayed" electrogram generated in the right ventricle as the depolarization reaches the recording site(s). The stimulus thus falls in the absolute refractory period of the ventricular myocardium. The stimulus does not depolarize any portion of the ventricles and true fusion does not occur. The "fusion" occurs on the ECG recording and not in the heart itself as in ventricular fusion. True sensing failure must always be excluded with long ECG recordings. Pacemaker stimuli falling beyond the surface ECG always indicate undersensing. A pseudopseudofusion beat (discussed later) is a variant of a pseudofusion beat seen in patients with dual chamber pacemakers.

Operational characteristics of a simple DDD pacemaker

1. *Ventricular channel*. As in a standard VVI pacemaker, the ventricular channel of an AV universal (DDD) pacemaker requires two basic timing cycles: the lower rate interval (corresponding to the programmed lower rate) and the ventricular refractory period. *The lower rate interval* (*LRI*) of a DDD pacemaker is the longest interval between consecutive ventricular stimuli without an intervening sensed P wave or from a sensed ventricular event to the succeeding ventricular stimulus without an intervening sensed P wave. The *ventricular refractory period* (*VRP*) is traditionally defined as the period during which the pacemaker is insensitive to incoming signals. The function of the ventricular refractory period in a DDD pacemaker is similar to that in a VVI pacemaker. Yet, many pacemakers can now actually sense within part of the refractory period to perform pacemaker functions (and influence certain timing cycles) other than resetting the lower rate interval. The pacemaker ventricular refractory period now focuses only on the lower rate interval which cannot be reset or reinitiated by a ventricular signal falling within the refractory interval. The ventricular refractory period starts with either a sensed or paced ventricular event and is usually equal after pacing or sensing. The lower rate (interval) of many DDD pacemakers is ventricular-based in that it is initiated by a paced or sensed ventricular event. Atrial-based lower rate timing is more complex and is discussed later.
2. *DDD pacing or VVI pacing with an atrial channel*. Now the pacemaker acquires an atrioventricular interval (*AVI*) and an upper rate interval. The *AVI* is the electronic analog of the PR interval and is designed to maintain AV synchrony between the atria and the ventricles. The AV interval starts from the atrial stimulus and extends to the following ventricular stimulus or it starts from the point when the P wave is sensed and also termi-

nates with the release of the ventricular stimulus. "Atrial tracking" is a term used to describe the response of a dual chamber pacemaker to a sensed atrial event which leads to the emission of a ventricular output pulse. Let us assume for now that the AV delay in our simple DDD pacemaker after atrial sensing is equal to that after atrial pacing though they may be different in more complex pacemakers. *The upper rate interval* is the speed limit to control the response of the ventricular channel to sensed atrial activity. For example, if the upper rate interval is 500 ms (upper rate = 120 p.p.m.), a P wave occurring earlier than 500 ms from the previous atrial event (atrial rate faster than 120 p.p.m.) will not be followed by a ventricular stimulus. Such an arrangement allows atrial sensing with 1:1 AV synchrony between the lower rate and the upper rate. The upper rate interval of any DDD pacemaker is a ventricular interval and is defined as the shortest interval between two consecutive ventricular stimuli or from a sensed ventricular event to the succeeding ventricular stimulus while maintaining 1:1 AV synchrony with sensed atrial events. In a simple DDD pacemaker the upper rate interval is intimately related to the electronic refractory period of the atrial channel as discussed later.

3. *Derived timing cycles*. The four basic timing cycles of a simple DDD pacemaker as already explained consist of: lower rate interval (*LRI*), ventricular refractory period (*VRP*), AV interval (*AVI*) and upper rate interval (*URI*). Additional timing intervals can be derived from these 4 basic intervals. Let us assume that the lower rate of our simple DDD pacemaker is ventricular-based. The atrial escape interval is the lower rate interval minus the AV delay. This is sometimes called the VA interval. The atrial escape interval starts with either a ventricular paced or sensed event and terminates with the release of the atrial stimulus. Although derived from two other intervals, the atrial escape interval is crucial in the analysis of DDD pacemaker function because it represents the interval the pacemaker uses to determine when the next atrial stimulus should occur after a sensed or paced ventricular event. In our DDD pacemaker with ventricular-based lower rate timing, the atrial escape interval always remains constant after programming the lower rate interval and AV delay. At this point our simple DDD pacemaker has four basic intervals and one derived interval. As the DDD pacemaker grows in complexity, we shall see how the upper rate interval is best thought of in terms of the total atrial refractory period rather than a truly fundamental interval as considered up to this point for the sake of simplicity in the construction of a simple DDD pacemaker.

4. *Influence of events in one chamber upon the other*. The operation of the two channels of a DDD pacemaker are intimately linked and an event detected by one channel generally influences the function of the other.
   (a) Atrial channel. As in the normal heart, an atrial event must always be followed by a ventricular event after some delay. A sensed atrial event alters pacemaker function in two ways:
      (i) it *triggers* a ventricular stimulus (after a delay equal to the AV interval) provided the ventricular channel senses no signal during the AV interval;
      (ii) it *inhibits* the release of the atrial stimulus that would have occurred at the completion of the atrial escape interval. In other words, it aborts the atrial escape interval which therefore does not time out in its entirety. This is self-evident because the atrial cycle starts with a sensed P wave and there is no need for atrial stimulation immediately after a spontaneous atrial event.

   Therefore the atrial channel functions simultaneously in the triggered mode (to deliver the ventricular stimulus for AV synchrony) and in the inhibited mode to prevent competitive release of an atrial stimulus after sensing a P wave. The function of the atrial channel can thus be depicted in terms of "TI" in the third position of the standard pacemaker code. Because the ventricular channel functions only in the inhibited mode, a DDD pacemaker can be coded as a DDTI/I device which would be more awkward but more correct than the traditional DDD designation.
   (b) Ventricular channel. A sensed ventricular event *outside the AV delay* such as a ventricular extrasystole (or premature ventricular complex) will inhibit the atrial and ventricular channels. The atrial escape interval in progress is immediately terminated and release of the atrial stimulus inhibited. The sensed ventricular event also inhibits the ventricular channel and initiates a new atrial escape interval. Thus both the atrial and ventricular channels are inhibited simultaneously. When a ventricular event is sensed *within the AV delay* there is no need for the pacemaker to release a ventricular stimulus at the completion of the AV delay because spontaneous ventricular activity is already in progress. Therefore the pacemaker aborts the AV delay

by virtue of the sensed ventricular event. The AV delay is thus abbreviated. The sensed ventricular event immediately starts a new atrial escape interval.

5. *Atrial refractory period*. It is axiomatic that the atrial channel of a DDD pacemaker must be refractory during the *AV delay* to prevent initiation of a new AV delay before completion of an AV delay already in progress.
   (a) The postventricular atrial refractory period (*PVARP*) begins immediately after the emission of a ventricular event and is the same after a ventricular stimulus or a sensed ventricular signal. An atrial signal falling within the *PVARP* cannot initiate a programmed AV interval. The *PVARP* is designed to prevent the atrial channel from sensing the ventricular stimulus, the far-field QRS complex (a voltage that can be seen by the atrial channel), very premature atrial ectopic beats and retrograde P waves. In the normal heart, an isolated ventricular event may occasionally be followed by a retrograde P wave because of retrograde ventriculoatrial (VA) conduction (the AV junction being a two-way street). Although this is a physiological phenomenon, it may be hemodynamically unfavorable if it becomes sustained. The *PVARP* should be programmed to a duration longer than the retrograde VA conduction time to prevent the atrial channel from sensing retrograde P waves.
   (b) The total atrial refractory period (*TARP*) is the sum of the AV delay and the *PVARP*. The duration of the *TARP* always defines the shortest upper rate interval or the fastest paced ventricular rate. The AV delay, *PVARP* and the upper rate interval are interrelated in a simple DDD pacemaker without a separately programmable upper rate interval. In such a system, the upper rate interval is controlled solely by the duration of the *TARP* according to the formula: upper rate (p.p.m.) = 60 000/*TARP* (ms). So far, the *TARP* is the upper rate interval in the simple DDD pacemaker being constructed by means of a few timing cycles.
   (c) Sensing in the refractory period. *True or false?* The first part of any refractory period consists of a blanking period during which the pacemaker cannot sense at all. The second part of the refractory period permits sensing and each detected event is often represented symbolically by a "refractory sense marker." In the atrium refractory sensed events cannot initiate an AV delay and in the ventricle they cannot start an atrial escape interval or lower rate interval. In one designation AR and VR depict an atrial refractory sensed event and ventricular refractory sensed event respectively. The rapid and irregular atrial rates in atrial fibrillation if sensed by the atrial channel will inscribe many AR events within the AV delay beyond the initial blanking period (initiated by atrial sensing or pacing) and multiple AR events in the *PVARP* beyond the initial postventricular atrial blanking period initiated by ventricular pacing or sensing.
6. *Upper rate interval vs.* PVARP *as a basic interval.* Now that the function of the *PVARP* is clear, it makes sense to consider the *PVARP* itself as a basic interval controlling the upper rate. In this way the upper rate interval can be demoted to a derived interval. This manipulation converts the upper rate interval of our evolving DDD pacemaker or the *TARP* (*AVI* + *PVARP*) to a derived function.
7. *The six intervals of a simple DDD pacemaker.* According to the above concepts, we now have a DDD pacemaker working with four basic intervals (lower rate interval, ventricular refractory period, AV delay and *PVARP*) and two derived intervals (atrial escape interval, and the *TARP* = upper rate interval). Such a pacemaker can function quite well provided the atrial stimulus does not interfere with the function of the ventricular channel. If it does, the disturbance is called AV *crosstalk* because the atrial stimulus, if sensed by the ventricular channel, can cause ventricular inhibition.
8. *The fifth fundamental timing cycle*. Prevention of crosstalk is mandatory and requires the addition of a brief ventricular blanking period beginning coincidentally with the release of the atrial stimulus. This is known as the *postatrial ventricular blanking* (*PAVB*) period. No signal can be detected during this blanking period. The ventricular channel then "opens" after this short blanking period so that ventricular sensing (with reset of the atrial escape interval and lower rate interval) can occur during the remainder of the AV delay. Obviously a long postatrial ventricular blanking period will predispose to ventricular undersensing. The addition of this important blanking interval yields a DDD pacemaker with five basic cycles and two derived cycles. This format was the basis of first generation DDD pacemakers that were clinically used and accepted. Even a sophisticated contemporary DDD pacemaker reduced to having only these seven intervals would function satisfactorily if appropriately programmed. Further addition of timing cycles represents re-

finements rather than essential elements of DDD pacing.

9. *Do we need more than seven intervals in our evolving DDD pacemaker?* Further refinements of DDD pacemaker function have introduced two other timing intervals:
   (a) ventricular safety pacing (*VSP*) to complement the blanking period in dealing with crosstalk – this function does not prevent crosstalk but merely offsets its consequences;
   (b) upper rate interval programmable independently of the *TARP* for a smoother upper rate response than the rather abrupt slowing provided by the *TARP* when it is the only interval controlling the upper rate (interval).
10. *Refractory periods.* In a DDD pacemaker how does an event in one channel affect the refractory period of the other? Four possible events may be considered: AP, AS, VS, VP.
   (a) VS and VP both initiate the *VRP* and *PVARP* starting simultaneously.
   (b) AP initiates the AV delay and an atrial refractory period extending through the entire duration of the AV delay. The AV delay is therefore the first part of the *TARP*, the second part being the *PVARP*. Release of AP initiates an important interval (postatrial ventricular blanking period) to prevent crosstalk which is a pacemaker disturbance where the ventricular channel senses the atrial stimulus (discussed later).
   (c) AS generates an atrial refractory period in the AV delay like AP but it is not associated with a postatrial ventricular blanking period because AS cannot induce crosstalk (discussed later).
11. *The faces of DDD pacing.* A DDD pacemaker with ventricular-based lower rate timing capable of dealing with four events (AS, AP, VS, VP) can behave in one of four ways judged by the examination of a single cycle starting with VS and the way the cycle terminates:
   (a) DVI: VS–AP–VP;
   (b) AAI: QRS–AP–QRS;
   (c) VDD: VS–AS–VP;
   (d) totally inhibited "mode" without stimuli.

   In the inhibited situation the RR interval (VS–VS) is shorter than the lower rate interval and the PR interval is shorter than the programmed AV delay. Inhibition does not always mean that the pacemaker senses both the atrial and ventricular signals. Indeed, in the presence of atrial undersensing, the ECG may show inhibition if the pacemaker (actually working in the DVI mode) emits no stimuli because the RR interval is shorter than the atrial escape interval.
12. *Ventricular pseudopseudofusion beats.* Remember that in a DDD pacemaker, a sensed ventricular event inhibits both the atrial and ventricular channels. A ventricular pseudofusion beat occurs when a ventricular stimulus falls within the spontaneous QRS before the intracardiac ventricular electrogram has developed sufficient amplitude to be sensed. In the same way an atrial stimulus can fall within the surface QRS complex before the intracardiac ventricular electrogram has developed sufficient amplitude to be sensed. In this situation when an atrial stimulus deforms the QRS complex, the arrangement is called a pseudopseudofusion ventricular beat to underscore that the process involves two chambers instead of one as is the case of pseudofusion beats.

Caveat: In the presence of normal atrial and ventricular sensing, a pacemaker stimulus falling within the QRS complex may be atrial (pseudopseudofusion) or ventricular (pseudofusion). In a device with a ventricular-based lower rate, the stimulus is atrial if it terminates the atrial escape interval, which is always constant. In a device with an atrial-based lower rate system (where atrial events control the lower rate), the stimulus is atrial if it terminates an interatrial interval equal to the lower rate interval.

Crosstalk and crosstalk intervals

In patients without an underlying cardiac rhythm, inhibition of the ventricular channel by crosstalk can be catastrophic. The postatrial ventricular blanking period (*PAVB*) starts with the atrial stimulus and is usually programmable from about 10 to 60 ms. Note again that no blanking period is in effect after atrial sensing. Some pacemakers are designed with an additional safety mechanism to counteract the inhibitory effect of crosstalk should the postatrial ventricular blanking period be unsuccessful. This special "safety period" is really a crosstalk detection window and is often described in pacemaker specifications as starting from the atrial stimulus. In fact, it cannot be functional until the brief postatrial ventricular blanking period has timed out. Nevertheless, the AV delay is often described as having two parts. The first part is the *ventricular safety pacing* (*VSP*) window which extends from the onset of the AV delay for a duration of 100–110 ms. During the *VSP* interval, a sensed ventricular signal does not inhibit the DDD pacemaker. Rather, it immediately *triggers* a ventricular stimulus delivered prematurely only at the completion of the *VSP* interval, producing a characteristic abbreviation of the paced *AVI* (AP–VP). If a QRS complex is sensed within the

VSP window, it will also trigger an early ventricular stimulus. However this triggered ventricular stimulus falls harmlessly within the QRS complex in the absolute period of the ventricular myocardium. In the second part of the AV delay beyond the *VSP* interval, a sensed ventricular signal inhibits the pacemaker in the usual fashion.

Manifestations of crosstalk

1. In pacemakers with a *VSP* interval, crosstalk will cause shortening of the paced AV delay (AP–VP). In a device with ventricular-based lower rate timing, the pacing rate will increase because the sum of the constant atrial escape interval and the abbreviated AV delay becomes less than the lower rate interval.
2. In pacemakers without a *VSP* interval, the ECG will show: (a) prolongation of the interval between the atrial stimulus and the succeeding conducted QRS complex to a value greater than the programmed AV delay; (b) if there is no AV conduction ventricular asystole will occur. The atrial pacing rate interval (there are no ventricular stimuli) will be shorter than the lower rate interval (atrial pacing rate faster than the lower rate) because the interval between two consecutive atrial stimuli becomes equal to the sum of the atrial escape interval (*AEI*) and the short *PAVB* because sensing of the atrial stimulus can only occur after the blanking period has timed out.
3. Crosstalk tachycardia. In pacemakers with *VSP* and ventricular-lower rate timing, a lower rate of 80 p.p.m. (*LRI* = 750 ms) yields an atrial escape interval of 450 ms if the AV delay = 300 ms. During continual crosstalk with an abbreviated paced AV delay (AP–VP) of 100 ms, the pacing interval becomes 450 + 100 = 550 ms corresponding to a rate of 109 p.p.m.

Caveat: VSP can be puzzling in the ECG without markers. When the atrial stimulus falls within a QRS complex and is invisible on the surface ECG, a single visible ventricular stimulus will fall beyond the QRS complex. This must not be interpreted as ventricular undersensing. To make the diagnosis, go back to the previous ventricular event and with calipers move to the end of the atrial escape interval when the atrial stimulus should have occurred. Then, add the *VSP* interval and its end should coincide with the late stimulus in question thereby proving it is ventricular and establishing normal pacemaker function. If *VSP* has not occurred and the QRS complex fell in the postatrial ventricular blanking period, add the AV delay to the atrial escape interval (measured as indicated) rather than the *VSP* interval.

Reminders:

1. The frequent occurrence of *VSP* involving spontaneous QRS complexes should immediately raise the possibility of atrial undersensing.
2. The opposite of AV crosstalk is ventriculoatrial (VA) crosstalk where the atrial channel senses ventricular activity. VA crosstalk is important in pacemakers with automatic mode switching (discussed later).

Increasing complexity: our simple DDD pacemaker grows to nine intervals

Many pacemakers have nine timing cycles, five related to the ventricular channel and four to the atrial channel. A ventricular paced or sensed event initiates: lower rate interval (*LRI*), upper rate interval or *URI* (independent of the *TARP*), *PVARP*, ventricular refractory period (*VRP*) and atrial escape interval (*AEI*). An atrial paced or sensed event initiates: *AVI*, *TARP* (derived as the sum of *AVI* and *PVARP*); an atrial paced event initiates the postatrial ventricular blanking period (*PAVB*) and the *VSP* interval.

A pacemaker with the capability of programming a longer upper rate interval independently of the *TARP* provides two levels of upper rate response. The first level defines the onset of the Wenckebach upper rate response and occurs when the P–P interval is shorter than the upper rate interval but longer than the *TARP*. The second level uses the *TARP* itself to define the onset of block when the P–P interval becomes shorter than the *TARP*.

Upper rate response of DDD pacemakers

The maximum paced ventricular rate of a DDD pacemaker can be defined either by the duration of the *TARP* or by a separate timing circuit controlling the ventricular channel. In general, upper rate limitation by only the *TARP* (as in our early DDD pacemaker) is less suitable because it produces a sudden fixed-ratio block such as 2:1 or 3:1 block. In contrast a smoother response occurs with a Wenckebach upper rate response, which requires a separate *URI* timing interval that must be longer than the *TARP*.

Fixed-ratio block

In this system the upper rate becomes a function of only the *TARP* (*AVI* + *PVARP*). As the atrial rate increases, any P wave falling within the *PVARP* is

unsensed and, in effect, blocked. The AV delay always remains constant. If the programmed upper rate is 120 p.p.m. (*TARP* = 500 ms) and the lower rate is 60 p.p.m., a 2:1 response will occur when the atrial rate reaches 120 p.p.m.,. One P wave is blocked (or unsensed) and the other initiates an AV delay and triggers a ventricular response. The situation is not as simple mathematically when the lower rate is 70 p.p.m. because the ventricular rate cannot fall below the lower rate. An upper rate response using fixed-ratio block may be inappropriate in young or physically active individuals because the sudden reduction in the ventricular rate with activity may be poorly tolerated.

Wenckebach upper rate response

The Wenckebach upper rate response requires a separately programmable upper rate interval. The purpose of the Wenckebach response is to avoid a sudden reduction of the paced ventricular rate (as occurs in fixed-ratio block) and to maintain some degree of AV synchrony at faster rates. The upper rate interval (*URI*) must be longer than the *TARP*. During the Wenckebach upper rate response, the pacemaker will synchronize its ventricular stimulus to sensed atrial activity. The pacemaker cannot violate its *URI*. Therefore upon atrial sensing, the pacemaker has to wait until the *URI* has timed out before it can release a ventricular stimulus. For this reason the AV delay (initiated by atrial sensing) must be extended to deliver the ventricular stimulus at the completion of the *URI*. The sensed AV delay gradually lengthens throughout the Wenckebach sequence but the ventricular rate remains constant at the programmed upper rate. Mathematically the AV delay must progressively lengthen in the Wenckebach progression simply because the *URI* cannot be violated and the atrial rate interval or P–P interval is shorter than the *URI* but longer than the *TARP*. Eventually a P wave will fall in the *PVARP* where it will not be followed by a ventricular stimulus and a pause will occur. In other words, the Wenckebach response maintains the constant *URI* at the expense of extension of the AV delay (AS–VP).

1. The maximum prolongation of the *AVI* represents the difference between the *URI* and the *TARP*.
2. With progressive shortening of the P–P interval, the Wenckebach upper rate response eventually switches to 2:1 fixed ratio block when the P–P interval becomes shorter than the *TARP*.
3. There are only two ventricular paced intervals during a Wenckebach upper rate sequence:
   (a) repeated ventricular pacing at the upper rate interval;
   (b) a longer interval (pause) between 2 successive ventricular beats following the undetected P wave in the *PVARP*; the pause may terminate with AS or AP and the ventricular event may be VP or VS according to circumstances.

   Some patients feel the pause at the end of a Wenckebach sequence as an uncomfortable sensation. The pause may be abbreviated or even eliminated with appropriate programming of the sensor function of a DDDR pacemaker. This process has been called sensor-driven rate-smoothing.
4. Let us consider two clinical examples.
   (a) a DDD pacemaker is programmed as follows: upper rate = 100 p.p.m. (upper rate interval = 600 ms); AV delay = 150 ms; *PVARP* = 250 ms. The *TARP* will be 250 + 150 = 400 ms. The pacemaker will therefore respond to an atrial rate faster than 100 b.p.m. by exhibiting Wenckebach sequences with the longest prolongation of the *AVI* being (*URI* minus *TARP*) or 200 ms. Thus the AV delay will vary from its programmed value of 150 ms to a maximum of 350 ms. Fixed-ratio block will occur when the P–P interval is shorter than the *TARP* (400 ms) or at an atrial rate of 150 b.p.m.
   (b) When the same DDD pacemaker is programmed with AV delay = 200 ms, *PVARP* = 250 ms, upper rate = 125 p.p.m. (upper rate interval = 480 ms), it would be difficult to produce an actual Wenckebach upper rate response. The maximum prolongation of the *AVI* would be (*URI* minus *TARP*) = 30 ms and its maximum duration = 230 ms. In this case, the pacemaker will respond with a Wenckebach sequence at an atrial rate of 125 b.p.m., but < 133 p.p.m. When the atrial rate exceeds 133 b.p.m., fixed-ratio block will occur (P–P shorter than *TARP* of 450 ms).

Remember the three important variables: *URI*, *TARP* and the P P interval (atrial rate)

1. *URI* shorter or equal to *TARP*. No Wenckebach response is possible.
2. *URI* > *TARP*:
   (a) P–P interval > *URI*, the pacemaker maintains 1:1 AV synchrony;
   (b) P–P interval < *URI*: when the P–P interval becomes shorter than the *URI* but longer than the *TARP*, that is, *URI* > P–P > *TARP*, the pacemaker responds with a Wenckebach upper rate response;
   (c) P–P < *TARP*: when the P–P interval is shorter than the *TARP*, the pacemaker can only re-

spond with a fixed-ratio form of upper rate limitation.

Duration of the AV interval and programmability of the upper rate

The sensed *AVI* (*sAVI*) initiated by AS (AS–VP) and not the one initiated by AP (*pAVI*), determines the point where fixed-ratio block occurs, i.e. when P–P interval < *TARP* or (AS–VP) + *PVARP*. In many pacemakers the *sAVI* (AS–VP) can be programmed to a shorter value than the *pAVI* (AP–VP) interval thereby shortening the *TARP* during sensing. Furthermore the *sAVI* (AS–VP) can decrease further with exercise according to the sensed atrial rate and/or sensor activity. This shortening on exercise mimics the physiological response of the PR interval and provides hemodynamic benefit and a more advantageous shorter *TARP*. (In some pacemakers the *TARP* can also shorten further on exercise because of an adaptive *PVARP*). Therefore a shorter *TARP* allows programming of a shorter (separately programmable) *URI* to permit a Wenckebach upper rate response to occur at faster atrial rate.

Lower rate timing of dual chamber pacemakers

Traditional DDD pacemakers are designed with ventricular-based lower rate timing. In this system a ventricular paced (VP) or ventricular sensed (VS) event initiates the lower rate interval (*LRI*) and the atrial escape interval. The atrial escape interval always remains constant. The *LRI* is the longest VP–VP or VS–VP interval without intervening atrial and ventricular sensed events. In atrial-based lower rate timing, the *LRI* is initiated and therefore controlled by atrial sensed or paced (AS or AP) events rather than ventricular events. The *LRI* becomes the longest AP–AP or AS–AS interval. The atrial escape interval becomes variable and adapts its duration to maintain a constant AP–AP or AS–AP interval equal to the *LRI*. The duration of the atrial escape interval can be calculated as the *LRI* minus the *AVI* immediately preceding the atrial escape interval in question. In an atrial-based lower rate system, ventricular premature complexes initiate either the basic atrial escape interval (as if it were ventricular-based) or a complete *LRI* according to design.

Table 1. Basic multiprogrammability.

Rate	Increase	(a) To optimize cardiac output; (b) to overdrive or terminate tachyarrhythmias; (c) to adapt to pediatric needs; (d) to test AV conduction in AAI pacemakers; (e) to confirm atrial capture using the AAI mode by observing a concomitant increase in the ventricular rate; (f) rate drop response for the treatment of vasovagal syncope. An abrupt fall in the spontaneous rate causes pacing at a higher rate (than the low basic pacing rate) for a given duration
	Decrease	(a) To assess underlying rhythm and dependency status; (b) to adjust the rate below the angina threshold; (c) to allow the emergence of sinus rhythm and preservation of atrial transport; (d) to test sensing function; (e) sleep mode to provide a lower rate during the expected sleep time. Some devices use an activity sensor to drop the rate automatically with inactivity
Output	Increase	To adapt to pacing threshold
	Decrease	(a) To test pacing threshold; (b) to program pacemaker according to chronic threshold to enhance battery longevity; (c) to reduce extracardiac stimulation (voltage rather than pulse duration)of pectoral muscles or diaphragm; (d) to assess underlying rhythm and dependency status.

continued

Table 1. Basic multiprogrammability (*continued*).

Sensitivity	Increase	To sense low amplitude P or QRS electrograms.
	Decrease	(a) To test sensing threshold; (b) to prevent T wave or afterpotential sensing by ventricular channel; (c) to avoid sensing extracardiac signals such as myopotentials.
Refractory period	Increase	(a) Atrial: to minimize sensing of the far-field QRS during AAI pacing
		(b) Ventricular: to minimize T wave or afterpotential sensing by the ventricular channel
	Decrease	(a) To maximize QRS sensing; (b) to detect early ventricular premature beats
Hysteresis		In the VVI mode to delay onset of ventricular pacing to preserve atrial transport function
Polarity	Conversion to unipolar mode	(a) To amplify the signal for sensing when the bipolar electrogram is too small; (b) to compensate temporarily for a defect in the other electrode
	Conversion to bipolar mode	(a) To decrease electromagnetic or myopotential interference; (b) to evaluate oversensing; (c) to eliminate extracardiac anodal stimulation
AVI	Increase or decrease to optimize LV function	(a) Differential: to permit a longer interval after an atrial paced event than a sensed atrial event
		(b) Rate-adaptive: to shorten the AV delay with an increase in heart rate
PVARP	Increase	To prevent sensing of retrograde P waves
PVARP extension after a VPC	On/off	To prevent sensing of retrograde P wave after a VPC
Postatrial ventricular blanking period	Increase	To prevent crosstalk
Ventricular safety pacing	On/off	To guarantee ventricular stimulation in the presence of crosstalk
Separately programmable upper rate	*URI* > *TARP*	To provide a smoother (Wenckebach) upper rate response and avoid abrupt slowing of the ventricular rate when *URI* = *TARP*

Phantom programming

This is unintended, inadvertent or mysterious reprogramming of a pacemaker. It may be the result of intentional reprogramming by an operator who made no record of it in the patient's chart. It may also be caused by electromagnetic interference unbeknown to the patient.

Programmability of lower rate

Patients with coronary artery disease and angina pectoris tend to have their pacemaker programmed to a low rate to avoid the precipitation of angina (chest pain). This may be true for VVI pacing but not for VDD, DDD, rate-adaptive DDD (DDDR) and rate-adaptive VVI (VVIR) pacing, which such patients tolerate well because their heart responds more efficiently on exercise. The upper rate, however, should be programmed cautiously. Patients with sick sinus syndrome and atrial tachyarrhythmias may benefit from overdrive suppression by increasing the pacing rate to 80 b.p.m., which may eliminate or reduce atrial tachyarrhythmias.

Endless loop tachycardia

Endless loop tachycardia (ELT), sometimes called pacemaker-mediated tachycardia, is a well-known complication of DDD, DDDR and VDD pacing. It represents a form of ventriculoatrial (VA) synchrony or the reverse of AV synchrony. Any circumstance that causes AV dissociation (separation of the P wave from the paced or spontaneous QRS complex) can initiate ELT only in patients who have the capability of retrograde VA conduction. The most common initiating mechanism is a ventricular premature complex (VPC) with retrograde VA conduction. (Table 2).

Reminder: ELT should be considered a complication of the past because it is almost always prevented by programming the PVARP to contain the retrograde P waves. Problems arise when the VA conduction time is very long and a long PVARP restricts programmability of the upper rate. In such cases, pacemakers use special automatic tachycardia-terminating algorithms.

When the atrial channel senses a retrograde P wave, a ventricular stimulus is issued at the completion of the AV delay which may have to be extended to conform to the *URI*. The pacemaker provides the antegrade loop of a process similar to the reentrant mechanism of many spontaneous tachyarrhythmias. VA conduction following ventricular pacing provides the retrograde limb of the reentrant loop. The atrial channel of the pacemaker again senses the retrograde P wave and the process perpetuates itself. The cycle length of ELT is often equal to the *URI* but it can be longer than the *URI* if retrograde VA conduction is delayed. The tachycardia is called a balanced ELT when its rate is slower than the programmed upper rate. The true programmed AV delay will be seen in ELT when the rate is slower than the programmed upper rate because the *AVI* is not extended. When the ELT is at the upper rate, the AV delay is extended to conform to the upper rate interval.

Reminder: Application of the magnet over the pacemaker immediately terminates ELT in virtually 100% of cases.

Caveat: The rate of ELT is not always at the programmed upper rate. In the DDI mode an endless loop with repetitive retrograde VA conduction will occur at the lower rate (no tachycardia is possible).

Table 2. Initiating mechanism of endless loop tachycardia.

1. Ventricular extrasystoles (commonest cause)
2. Subthreshold atrial stimulation (commonly used for testing)
3. Atrial extrasystole with prolongation of AV delay to conform to the programmed upper rate interval > total atrial refractory period
4. Application and withdrawal of the magnet
5. Decrease in atrial sensitivity; undersensing of anterograde P waves with preserved sensing of retrograde P waves
6. Myopotential sensing usually by the atrial channel
7. Programmer electromagnetic interference sensed by the atrial channel only
8. Excessively long AV delay
9. Programming the VDD mode when the sinus rate is slower than the programmed lower rate.
10. Treadmill exercise (rarely) and increase in sinus rate with Wenckebach upper rate response and AV delay extension
11. Sensing of a far-field signal by the atrial lead, usually the far-field R wave

Diagnosis and prevention of endless loop tachycardia

The presence of retrograde VA conduction and its duration must always be determined (Table 3). Rarely, retrograde VA conduction is intermittent.

The maneuvers to initiate ELT are repeated until appropriate programming of the pacemaker prevents induction of tachycardia. In general the *PVARP* should be programmed at least 50 ms longer than the VA conduction time. A *PVARP* of 300 ms offers protection against ELT in most patients with retrograde conduction (Table 4).

The best way to initiate ELT is to program subthreshold atrial stimulation, the shortest *PVARP* and a lower rate faster than the spontaneous sinus rate.

Caveat: Programming a long PVARP will limit the upper rate. This may be important in vigorous or young patients.

Table 3. Situations permitting evaluation of retrograde VA conduction.

1. Programming to VVI mode
2. Programming the atrial output to subthreshold level in the DDD mode
3. Application and withdrawal of the magnet
4. Holter monitoring
5. Treadmill exercise (rarely)

Table 4. Programmability for the prevention of endless loop tachycardia.

1. Program *PVARP*
2. Automatic *PVARP* after VPC (defined by a pacemaker as a ventricular event not preceded by a P wave; thus, a true VPC will not be labeled a VPC if preceded by a P wave)
3. Adaptive *PVARP*
4. Programmable sensitivity: 60–75% of anterograde P waves are at least 0.5 mV larger than retrograde P waves
5. Shortening of the AV delay
6. Programming to a nontracking mode such as DDI is no longer acceptable

Repetitive nonreentrant VA synchrony: the cousin of endless loop tachycardia

Endless loop tachycardia (ELT) is a form of repetitive VA synchrony and as mentioned it is a reentrant or circus movement tachycardia. Repetitive VA synchrony can occur in the VVI or VVIR with continual retrograde VA conduction where it may cause hemodynamic impairment and pacemaker syndrome. Repetitive VA synchrony can also occur in the DDD or DDDR mode when a paced ventricular beat causes retrograde VA conduction but the retrograde P wave is unsensed (unlike ELT) because it falls within the *PVARP*. Under certain circumstances, this form of VA synchrony can become self-perpetuating when the pacemaker continually delivers an ineffectual atrial stimulus (despite being well above the pacing threshold under normal circumstances) in the atrial myocardial refractory period generated by the preceding retrograde P wave. The potential reentrant circuit does not close as in ELT and this arrhythmia is often labeled as being nonreentrant. Both ELT and repetitive nonreentrant VA synchrony depend on VA conduction and are physiologically similar. Both share similar initiating and terminating mechanisms. Repetitive nonreentrant VA synchrony depends on a short atrial escape interval (relatively fast lower rate and/or a long AV delay) and a relatively long VA conduction time. Thus, it is more likely to occur during sensor-driven faster pacing rates. The process may therefore occur when programming a very long AV delay to promote AV conduction and normal ventricular activation. Occasionally during ELT, magnet application over the pacemaker can cause a locked arrangement similar to repetitive nonreentrant VA synchrony (with preservation of VA conduction) so that removal of the magnet reinitiates ELT.

Types of dual chamber pacemakers

Simpler pacing modes can be easily derived from the DDD mode by the removal of certain intervals and equalizing others. All retain a fundamental *LRI*, ventricular refractory period, AV delay initiated by atrial pacing except for the DOO mode which has only an AV delay and *LRI*.

DVI mode

The AV sequential (DVI) mode may be considered as the DDD mode with the *PVARP* lasting through the entire duration of the atrial escape interval. As the

AV delay is always refractory in a DDD pacemaker, the *TARP*, in effect, lasts through the entire *LRI*. No *URI* can exist because atrial sensing is impossible. Therefore, the *LRI*, *TARP* and *URI* are all equal. Crosstalk intervals are retained. The DVI mode is rarely used and is obsolete as a primary pacing mode. The terms "committed" or variants thereof are therefore obsolete descriptions of the DVI mode.

DDI mode

The DDI mode may be considered as the DDD mode with equal *URI* and *LRI*. This concept facilitates understanding of complex rhythms generated by this mode although this conceptualization is not recommended by some experts. Nevertheless, it is easy to remember and apply. Remember the DDTI/I designation for the DDD mode. The DDI mode is simply created by removing the "T" from the atrial channel. Thus atrial sensing occurs but no "T" function is possible. In other words, a sensed P wave cannot trigger a ventricular stimulus and a programmed *AVI* cannot occur after atrial sensing. The programmed AV delay can only exist as the AP–VP interval. This means that atrial tracking cannot occur. The DDI mode will therefore always exhibit a constant ventricular paced rate equal to the *LRI*. There is no *URI* (or a *URI* equal to the *LRI*). A *PVARP* is retained because atrial sensing occurs. Crosstalk intervals are retained. In the early days of DDD pacing, the DDI mode was useful in patients with AV block and paroxysmal atrial tachyarrhythmias because it prevented rapid ventricular pacing during tachycardia. The use of the primary continuous DDI mode for this problem has been superseded by automatic mode switching of a DDD pacemaker to the DDI mode upon the detection of an atrial tachyarrhythmia and reversion to the DDD mode automatically upon termination of tachycardia.

During DDI pacing with atrial fibrillation and AV block, many AR markers (atrial refractory sense events) will be seen in the atrial refractory period (in the AV delay and the *PVARP*) and AS markers outside the atrial refractory period. AS cannot start an AV delay. The AR markers provide diagnostic representation of the underlying arrhythmia and insight as to how the pacemaker activates the automatic mode switching function.

VDD mode

The original atrial synchronous pacemaker was the VAT system without ventricular sensing. Then, ventricular sensing was added (VAT + VVI = VDD). The VDD mode functions like the DDD mode except that the atrial output is turned off. The required timing cycles include *LRI*, *URI*, *AVI* and *PVARP*. The omitted atrial stimulus begins an implied AV delay during which, according to traditional design, the atrial channel is refractory. In the absence of atrial activity, the VDD mode will continue to pace effectively in the VVI mode (at the *LRI* of its DDD parent) because the VDD keeps all the basic cycles of the DDD mode despite the missing atrial output. This is an important disadvantage of the VDD mode because VVI pacing during sinus bradycardia may be poorly tolerated and cause pacemaker syndrome. No crosstalk intervals are required because there is no atrial stimulation in the VDD mode.

Reminder: One can easily derive the function and timing cycles of all dual chamber pacemakers starting with a thorough knowledge of the timing cycles of a DDD pacemaker.

Caveats:
There are two types of response to the sensed P wave in the VDD mode according to design.

1. A P wave falling in the implied AV delay is not sensed. The *LRI* always remains constant.
2. In some pacemakers a P wave in the implied *AVI* can be sensed and actually reinitiates an entirely new AV delay so that the VS–VP or VP–VP interval becomes longer than the programmed (ventricular-based) *LRI*. This produces a form of hysteresis with the maximum extension of the *LRI* being equal to the AS–VP interval.

Overdrive suppression and the underlying rhythm

Continuous pacing may suppress the underlying spontaneous rhythm, a phenomenon called overdrive suppression. Thus, the sudden interruption of pacing may cause prolonged asystole because it takes time for a dormant rhythm to "wake up." The underlying rhythm is determined by programming to the VVI and *gradually* reducing the rate, sometimes to as low as 30 p.p.m. Often a slow rhythm "warms-up" and will emerge. Most patients tolerate such a slow rate of pacing. A patient that has a poor underlying rhythm is often labeled as being "pacemaker dependent." This is a vague term which has never been clearly defined. It may be defined as the occurrence of severe or life-threatening symptoms with failure to pace as may occur with lead dysfunction, battery failure or electromagnetic interference. Pacemaker dependency may be tested by totally and abruptly inhibiting the pacemaker, but this may dangerous. The emergence of a slow rhythm during gradual reduction of the pacemaker rate to 30 p.p.m. does not

mean that the patient is not pacemaker-dependent. The presence of pacemaker dependency should be displayed prominently on the cover of the pacemaker chart.

Caveat: Always have two programmers on hand in case one malfunctions during induced severe bradycardia or asystole.

Pacemaker hemodynamics

The early pacemakers had little in the way of electronics and no hemodynamic refinement. VVI pacing was basically nonphysiologic and ignored the atrium. Pacemaker syndrome was relatively common. The advent of DDD pacing was hailed as the universal pacing mode. Patients with sick sinus syndrome and poor atrial chronotropic function, however, complained of fatigue and the inability to perform exercise to a level that they thought reasonable because the heart rate did not increase during exercise. The subsequent development of rate-adaptive pacemakers (with artificial sensors in addition to the natural P wave sensor) permitted a pacemaker to respond by increasing its rate similarly to the normal heart on effort. These pacemakers improved effort tolerance in patients with bradycardia at rest or with activity. Many older patients have little ability to increase their cardiac output by increasing left ventricular contractility and therefore stroke volume (volume of blood ejected per heart beat), so that an increase in heart rate is their only way to increase cardiac output on effort. The cardiac output may increase by as much as 300% on exercise by rate increase alone. Unfortunately the settings on rate-adaptive pacemakers are often left on factory settings unless the patient becomes symptomatic or the physician has a particular interest in the technology.

AV synchrony

The atrial contribution provides about 15–30% of the cardiac output (volume of blood in liters ejected by the heart per minute) at rest in individuals with normal LV systolic function. Although the atrial contribution plays little or no role on exercise when heart rate is basically the only determinant of cardiac output, AV synchrony at rest is vital to prevent pacemaker syndrome and atrial tachyarrhythmias. The loss of AV synchrony can be especially detrimental in patients with LV diastolic dysfunction where the systolic function can be normal but the ventricle is stiff and noncompliant, as in hypertrophy from hypertension. Furthermore, patients with heart failure often do not tolerate loss of AV synchrony.

Reminder: Loss or inappropriate AV synchrony is the cause of pacemaker syndrome. The optimal AV delay for the individual patient cannot be predicted but can be evaluated by echocardiography.

Ventricular activation sequence

While the AV delay and rate responsiveness are essential components of pacemakers, the role of the ventricular activation sequence is presently becoming recognized. In patients with sick sinus syndrome and normal AV conduction, AAI or AAIR pacing (associated with a small risk of AV block even in highly selected patients) provides the best hemodynamics because it preserves normal ventricular activation. Long-term RV pacing, which by necessity causes abnormal LV activation (similar to left bundle branch block), may cause long-term deterioration of LV function or precipitate congestive heart failure in patients with poor LV function. This disturbance seems to be based on the cumulative duration of right ventricular pacing. For this reason, the AV delay should be programmed to promote AV conduction if possible so that the advantage of normal ventricular depolarization offsets the depressant effect of pacing on the LV. Patients with relatively normal AV conduction who require minimal or backup pacing could be paced with a slow lower rate such as 40–50 p.p.m. to allow a spontaneous rhythm most of the time with the hope of preventing long-term deterioration of LV function. Patients with a long PR interval ≥ 0.28 s require ventricular pacing for optimal hemodynamic benefit because the shorter AV delay offsets the negative impact of abnormal pacing-induced LV depolarization.

Biventricular pacemakers are used to treat congestive heart failure in patients with poor LV function and left bundle branch block. The latter produces an inefficient left ventricular contraction because of abnormal ventricular depolarization and contraction. Biventricular pacing produces "resynchronization" by promoting a more physiologic pattern of depolarization and a more efficient LV contraction.

Caveat: Programming a long AV delay to promote normal AV conduction may increase the risk of endless loop tachycardia and repetitive nonreentrant VA synchrony by promoting retrograde VA conduction. A long AV delay may also favor the delivery of ventricular stimulation on the T wave (vulnerable period).

Rate-adaptive pacemakers

A sensor monitors the need for a faster pacing rate according to activity and works independently of intrinsic atrial activity. A VVI pacemaker with a rate-adaptive function is coded as a VVIR pacemaker. A DDDR pacemaker is thus a DDD device with rate-adaptive function or rate modulation. However the VDDR mode is a misnomer because such a mode operates in the VDD mode except when it is sensor-driven, when the pacing mode becomes VVIR.

Five basic parameters can be programmed in sensor-driven pacemakers: sensor threshold, lower rate, upper sensor rate, upper tracking (or atrial-driven) rate, and sensor slope. Unfortunately many pacemakers are left at their nominal settings (out of the box) which may not be optimal for some patients.

The sensor threshold is the minimum degree of sensor activation required to initiate an increase in heart rate. In other words, it sets the lowest level of sensor activation that will be counted and used for rate control. Threshold settings may be numeric or descriptive. Sedentary patients may require a more sensitive setting. The sensor slope determines the rate of change of the heart rate in response to sensor activation. Increasing the slope will result in an increased pacing rate for the same amount of activity. The normal sinus node produces a linear increase in the heart rate during exercise. The slope can be variable, however, and depends on the degree of conditioning. Some manufacturers have designed pacemakers with an autoresponsive slope and threshold. The pacemaker learns the appropriate settings based on the patient's activity. These automatic system are not perfect but are better than empiric systems or not programming the rate-adaptive response.

The pause in the Wenckebach upper rate response can be attenuated or even eliminated by appropriate programming of a DDDR pacemaker. This process is called sensor-driven rate smoothing.

The sensor in DDDR pacemakers can also influence intervals other than the *LRI*. These include:

1. the AV delay that shortens on exercise to mimic physiologic shortening of the *PR* interval;
2. the *PVARP*.

Shortening of the *PVARP* on exercise coupled with adaptive shortening of the *AVI* produce substantial shortening of the total atrial refractory period. This allows programming of a faster upper rate. An adaptive *PVARP* allows programming of a relatively long *PVARP* at rest when endless loop tachycardia is likely to occur. Initiation of endless loop tachycardia is quite unusual on exercise with fast atrial-driven ventricular pacing when a shorter *PVARP* is safe.

Programming the pacemaker

An easy way to program the sensor-driven response, is to have the patient walk up and down and adjust the parameters accordingly. Avoid overprogramming the threshold response, which will produce an excessively fast pacing rate poorly tolerated by patients.

Table 5. Characteristics of commonly used pacing modes.

Characteristics	VVI	VVIR	AAI	AAIR	DDD	DDI	DDDR	DDIR
Simplicity	+++	+++	++	++	+	+	–	–
AV synchrony	–	–	+	+	+	+[a]	+	+[a]
Potential for pacemaker syndrome	+	+	–	–	–	–	–	–
Normal LV activation	–	–	+	+	–[b]	–[b]	–[b]	–[b]
Propensity to endless loop tachycardia	–	–	–	–	+	+[c]	+	+[c]
Tracking of supraventricular tachycardia	–	–	–	–	+	–	+	–
Contraindicated in AV block	–	–	+	+	–	–	–	–
Increase of pacing rate in atrial chronotropic incompetence	–	+	–	+	–[d]	–	+	+
Cost	–	+	–	+	++	++	+++	+++

[a] In the DDI mode, if normal sinus rhythm is faster than the programmed rate, and in the DDIR mode if normal sinus rhythm is faster than the sensor-driven rate, AV dissociation with hemodynamic disadvantage is frequent in patients with AV block.
[b] Unless AV delay is prolonged to allow for normal antegrade conduction.
[c] Endless loop without tachycardia at the lower rate or at the sensor-driven rate.
[d] Ventricular pacing rate does not increase if the sinus rate does not increase on exercise.

Caveat: After the implantation of a pacemaker, fluid in the pacemaker pocket may dampen vibrations and the response of activity rate-adaptive pacemakers. If these devices are programmed too early, there may be an excessive rate response several weeks later after the absorption of fluid. It seems wise to leave the rate-adaptive function of activity-driven devices turned off soon after implantation to prevent constantly changing pacing rates when the patient turns in bed, etc. Such fluctuations may cause confusion for the personnel monitoring the patient.

The pacemaker stimulus

Contemporary digital ECG recorders distort the pacemaker stimulus, so it may become larger and show striking changes in amplitude and polarity. Digital recorders can also miss some of the pacemaker stimuli because of sampling characteristics. Diagnostic evaluation of the pacemaker stimulus is only possible with analog machines. Many inkjet recorders and ECG machines with a stylet writer are analog recorders. With such recorders, the direction and amplitude of the pacemaker stimulus may yield valuable information about lead displacement or defects. A bipolar lead with an insulation defect may exhibit a very large stimulus artifact on the electrocardiogram (unipolar–bipolar phenomenon) and pace normally in contrast to the tiny deflections with an intact bipolar lead.

Caveats:

1. Static interference may generate deflections mimicking pacemaker stimuli. Careful scrutiny of the deflections often suggests they are not pacemaker stimuli. When in doubt, measure the timing cycles to and from the deflection in question and establish the lack of relationship to pacemaker function.
2. The interval from the stimulus to the onset of cardiac depolarization is called latency. The normal value is 40 ms or less. If there is a relatively long isoelectric (zero) interval from stimulus to the QRS or P wave, the commonest cause is isoelectric depolarization in the ECG lead in question. Confirmation requires the recording of several ECG leads simultaneously to demonstrate the true onset of cardiac depolarization. Hyperkalemia is a common cause of increased latency. Other causes of latency include serious metabolic disorders, right ventricular infarction and terminal situations.

Magnet mode

The magnet mode refers to the response of a pacemaker when a magnet is applied over it. The magnet closes the special reed-switch within the pulse generator causing the device to pace at the asynchronous mode at the magnet rate. The behavior of the magnet mode varies according to the manufacturer and so does the magnet rate. The magnet mode is used to assess pacemaker function and battery depletion. The magnet mode can be programmed "off" in some pacemakers.

QRS patterns during ventricular pacing

Pacing from the RV apex produces negative paced QRS complexes in the inferior leads (lead II, lead III and lead aVF) simply because the activation starts in the inferior part of the heart and travels superiorly away from the inferior leads. The mean QRS frontal plane axis is superior either in the left or the right superior quadrant. Displacement of the electrode towards the RV outflow tract should be suspected whenever the frontal plane QRS axis shifts to where it is considered "normal" (at least for spontaneous QRS complexes) so that the inferior leads QRS complexes become positive. As stated pacing from RV outflow tract produces a dominant R wave in the inferior leads and may generate qR, QR, or Qr complexes in leads I and aVL. The axis of the paced ventricular beats moves in a clockwise fashion to the so-called "normal" sites (for spontaneous beats) and then to the (inferior) right quadrant as the pacing lead approaches the pulmonary valve. Occasionally with slight displacement of the pacing lead from RV apex to the RV outflow tract, leads I and aVL may register a qR complex in conjunction with the typical negative complexes of RV apical stimulation in the inferior leads. This qR pattern must not be interpreted as a sign of myocardial infarction. RV pacing from any site does not produce qR complexes in V5 and V6. A qR (Qr) complex in the precordial or inferior leads is always abnormal in the absence of ventricular fusion. Right ventricular outflow tract pacing produces a left bundle branch block pattern in the precordial leads similar to that from right ventricular apical pacing.

Dominant R wave in lead V1

A dominant R wave in V1 during ventricular pacing has been called a right bundle branch block (RBBB) pattern of depolarization, but this terminology is

misleading because this pattern is often not related to RV activation delay. A dominant R wave of the paced beat in the right precordial leads occurs in approximately 8–10% of patients with uncomplicated RV apical pacing. The position of V1 and V2 should be checked because a dominant R wave can sometimes be recorded at the level of the third intercostal space during uncomplicated RV pacing. The pacing lead is almost certainly in the RV (apex or distal septal site) if V1 and V2 are negative when recorded one space lower (fifth intercostal space). Furthermore the "RBBB" pattern from pacing at the RV sites results in a precordial vector change from positive to negative by V3. Therefore a tall R wave in V3 and V4 signifies that the lead is not in the RV provided ventricular fusion from spontaneous AV conduction is excluded.

Unintended endocardial left ventricular pacing

Unintended and unsuspected passage of a pacing lead into the LV cavity occurs via the subclavian artery or an atrial septal defect (patent foramen ovale). An LV lead is a potential source of cerebral emboli and stroke. The access sites to the LV can be easily identified by the RBBB pattern during pacing, standard chest radiographs and transesophageal echocardiography.

Reminder: Always look at lead V1 for the absence of a dominant R wave during ventricular pacing.

Complications of pacemakers

Two major groups of complications are associated with pacemaker implantation: (a) nonelectrical complications including acute complications at the time of implantation such as pneumothorax and complications of lead placement and pocket formation; (b) electrical complications.

Nonelectrical complications

Infection

Transesophageal echocardiography is superior to transthoracic imaging for the detection of pacing lead vegetations in patients with intravascular infected pacemakers (endocarditis). Vegetations may occur in the right atrium, right ventricle and the tricuspid valve. Vegetations are best visualized by transesophageal echocardiography.

Perforation

Perforation of a cardiac chamber is now an uncommon complication. It may occur at the time

Table 6. Dif culties in the diagnosis of myocardial infarction during ventricular pacing.

1. Large unipolar stimuli may obscure initial forces, cause a pseudo Q wave and false ST segment current of injury
2. Fusion beats may cause a pseudoinfarction pattern (qR/Qr complex or notching of the upstroke of the S wave)
3. QRS abnormalities have low sensitivity (many false negatives) but high specificity (few false positives). These include qR or Qr patterns and Cabrera's sign in the appropriate leads.
4. Retrograde P waves may simulate Cabrera's sign
5. Diagnosis of acute MI:
   - signs in QRS complex are not useful for the diagnosis of acute MI
   - looking at the underlying rhythm: cardiac memory. Repolarization ST–T wave abnormalities (mostly T wave inversion) in the spontaneous rhythm may be secondary to RV pacing per se and not related to ischemia or non Q wave MI
   - differentiation of MI vs. ischemia may be impossible
   - differentiation of acute MI vs. old or indeterminate age MI may be impossible if old MI is associated with prominent chronic T wave changes usually indicative of an acute process
   - ST segment abnormalities may help the diagnosis of acute myocardial infarction during ventricular pacing. ST elevation ≥ 5 mm in predominantly negative paced QRS complexes is the best marker. ST depression ≥ 1 mm in V1, V2, and V3 and ST elevation ≥ 1 mm in leads with a concordant (same direction) QRS deflection. So-called primary T wave abnormalities where the T wave is in the same direction as the QRS complex are not diagnostically useful during RV pacing

Table 7. Nonelectrical or arrhythmic complications.

Venous access	Pneumothorax Hemothorax Air embolism Brachial plexus injury Thoracic duct injury Trauma to the subclavian artery Hematoma
Pacemaker pocket	Infection, septicemia, etc. Conservative therapy is often unsuccessful and removal of the entire system may be required Hematoma/seroma Erosion Pacemaker migration Twiddler's syndrome Muscle stimulation from either a flipped but normally functioning unipolar or extravascular insulation defect Chronic pain including subcuticular malposition of the pulse generator
Intravascular	Subclavian or inominate vein thrombosis Thrombosis of superior vena cava Coronary sinus dissection or perforation during implantation of a left ventricular lead Large right atrial thrombus Endocarditis with vegetations Manifest pulmonary embolism (rare) Cardiac perforation Cardiac tamponade Entanglement of lead in the tricuspid valve and ruptured chordae Tricuspid insufficiency Pericardial rub
Lead problems	Displacement Malposition in the coronary venous system Endocardial left ventricular malposition across a patent foramen ovale or via subclavian arterial puncture (or via atrial or ventricular septum defect) Right ventricular perforation or lead perforation of the interventricular septum Diaphragmatic pacing. Left side with or without right ventricular perforation and right side by phrenic nerve stimulation by atrial pacing Intercostal muscle stimulation due to right ventricular perforation Post pericardiotomy syndrome (pericarditis etc.) with or without lead perforation Intracardiac rupture of lead during attempt to remove old or broken lead

of implantation or days afterwards. Perforation may be catastrophic when it occurs acutely at the time of implantation, but it is less dramatic when recognized after initial implantation. Perforation of an atrial lead is quite rare. In ventricular perforation, the lead lies more commonly in the pericardial space and less commonly across the ventricular septum. Perforation may be asymptomatic or cause chest pain from pericarditis. It causes intermittent or complete failure to pace and/or diaphragmatic pacing. Diaphragmatic stimulation can also occur in the absence of perforation. Obvious intercostal muscle stimulation may also occur with perforation. The ECG may show a right bundle branch pattern

(dominant R wave) in lead V1 during pacing if the lead stimulates the left ventricle. The chest radiograph may show the lead beyond the cardiac shadow. Transesophageal echocardiography is superior to transthoracic echocardiography in delineating the entire course of a pacing lead. A two-dimensional echocardiogram may be diagnostic in localizing the tip of the lead outside the heart and may show a pericardial effusion. Multiple views are required to follow the lead and localize the tip beyond the epicardium. Echocardiography is superior to radiography, conventional and spiral computed tomography (CT) scan for the diagnosis.

Accessory muscle stimulation

Accessory muscle stimulation may occur at several sites.

1. Contraction of the diaphragm. Left diaphragmatic stimulation by pacemaker stimuli may occur during traditional pacing with and without lead perforation of the RV. Perforation must always be excluded when diaphragmatic pacing is observed. Late appearance of diaphragmatic pacing suggests an insulation defect of the pacing lead. Left ventricular pacing from a coronary vein (in the absence of perforation) is an important and troublesome cause of left diaphragmatic pacing during biventricular pacing for the treatment of heart failure. Contraction of the right diaphragm is related to a malpositioned right atrial electrode.
2. Left intercostal muscle stimulation is invariably the result of ventricular lead perforation.
3. Deltopectoral muscle stimulation (twitching) owing to:
   (a) an extravascular lead insulation leak. In the case of a bipolar pacemaker, it always indicates an insulation problem;
   (b) a unipolar pacemaker that has flipped over in a large pocket so that the anodal plate faces the skeletal muscle;
   (c) a normally functioning unipolar pacemaker without any other problems. This is now rare with better pacemaker design but can occur at high voltage outputs.

Decreasing the output voltage with preservation of an adequate safety margin often minimizes or eliminates accessory muscle stimulation. Decreasing the pulse duration alone is usually ineffective.

Pacemaker syndrome

Pacemaker syndrome refers to a clinical situation in the pacemaker patient caused by inadequate timing of atrial and ventricular contractions. The main problems are reduced cardiac output and hypotension. The symptoms may be obvious in about 10–20% of patients with VVI pacemakers, but may be more common with less severe manifestations. The clinical manifestations can be subtle and easily missed. Obvious symptoms include dizziness, syncope, dyspnea (precipitation of pulmonary venous congestion), fatigue, pulsations in the neck, and cough. Pacemaker syndrome occurs typically in patients with intermittent VVI pacing, mostly with retrograde VA conduction. The diagnosis is supported by comparing the blood pressure during AV synchrony and during ventricular pacing. During ventricular pacing the systolic pressure should drop 20 mmHg or more for the diagnosis. The pacemaker syndrome is most commonly associated with retrograde ventriculoatrial (VA) conduction but it may also be caused by complete AV dissociation without retrograde VA conduction. Patients with a VVIR pacemaker may develop pacemaker syndrome only during exercise when the spontaneous rate is adequate at rest but not on exercise when pacing supervenes. The treatment of the pacemaker syndrome is restoration of AV synchrony. The implantation of a dual chamber pacemaker does not necessarily prevent pacemaker syndrome if the mode or programming fails to provide appropriate AV synchrony. It is therefore important to optimize the AV delay of DDD pacemakers for maximum hemodynamic benefit.

Caveat: Do not attribute symptoms to "old age" because pacemaker syndrome is basically an iatrogenic condition which is easily reversible.

Electrical complications

The various complications and methods of troubleshooting are presented in Tables 8–17. Loss of capture by visible stimuli is presented in the illustrated section.

Never neglect determination of atrial capture in dual chamber pacemakers

The presence of atrial stimuli does not mean atrial capture. Unsuspected atrial fibrillation is a common cause of lack of atrial capture. Telemetered AP markers simply reflect release of AP and cannot indicate successful atrial capture.

Table 8. Absence of pacemaker stimuli.

1. Normal situation: total inhibition of pacemaker when the intrinsic rate is faster than the preset pacemaker rate
2. Hysteresis with normal pacemaker function: escape interval after ventricular sensing is longer than the automatic interval during pacing
3. Pseudomalfunction: overlooking tiny bipolar stimuli in the ECG
4. Normal pulse generator with poor anodal contact:
   (a) subcutaneous emphysema with air preventing contact of anode of unipolar pacemaker with the tissues. This occurs soon after subclavian vein puncture
   (b) air entrapment in the pacemaker pocket preventing contact of anode of unipolar pacemaker with the tissues; this may occur after battery replacement when a smaller (new) pacemaker is inserted in a large pacemaker pocket
5. Lead problems: fracture, loose connection or set screw problem on the pacemaker itself
6. Abnormal pulse generator:
   (a) total battery depletion
   (b) component failure
   (c) sticky reed switch (magnet application produces no effect)
7. Extreme electromagnetic interference
8. Oversensing of signals originating from outside or inside the pulse generator
9. Filter settings of ECG recorder masking pacing stimuli
10. Saturation of ECG amplifier

Table 9. How to test for atrial capture.

1. If the paced P wave is not discernible in the 12-lead ECG, record the ECG at double standardization to bring out P waves and tiny bipolar stimuli; faster paper speed may help
2. In the presence of relatively normal AV conduction, program the AAI or AOO mode; use several pacing rates to demonstrate the consistent relationship of the atrial stimulus to the succeeding spontaneous conducted QRS complex
3. In patients with AV block, reduce the pacing gradually to 30 p.p.m.; this is often well tolerated. Then use the AAI or AOO at various fast rates to determine atrial capture by looking at the P wave configuration and rate which must correspond to the pacing rate
4. A paced P wave may be difficult to see if the AV delay is too short. A relatively late P wave can be unmasked by prolonging the AV delay. A "late" P wave from the atrial stimulus usually indicates interatrial conduction delay and the risk of delivering the P wave too late to provide appropriate AV synchrony. In other words the atrial transport function provided by atrial pacing may be largely wasted if the P wave is too close to the paced QRS complex. In severe cases the paced P wave occurs inside the paced QRS complex. Such a patient requires careful programming of the AV delay under echocardiographic control and evaluation for pacemaker syndrome
5. Shorten the AV delay; if the paced QRS morphology changes, it means that there was ventricular fusion with the spontaneous QRS complex at the longer AV delay and therefore atrial capture giving rise to AV conduction
6. In patients with relatively fast sinus rhythm, program the DVI mode which provides competitive atrial pacing beyond the atrial myocardial refractory period
7. In patients with retrograde VA conduction, subthreshold atrial stimulation causes retrograde P waves identifiable in the ST segment. Such P waves reflect lack of atrial capture and may be documented with event markers. Their disappearance constitutes presumptive evidence of successful atrial capture
8. Atrial capture can also be evaluated with only the programmer using its ECG recorder and markers. Increase the pacing rate above the intrinsic rate and decrease the atrial output. Lack of capture will cause AS, AR and AP markers to march through in a seemingly haphazard way. Increase the atrial output gradually until the AS and AR markers disappear. At that point atrial capture has occurred. This provides an easy way to determine the pacing threshold without a regular ECG machine

Table 10. Causes of undersensing.

Normal situations	Ventricular premature complexes with a small electrogram different from that of sensed conducted beats Beats falling inside blanking or refractory periods. Oversensing can cause undersensing because an oversensed signal generates a refractory period into which a succeeding physiologic signal cannot be sensed*
Abnormal situations	Poor lead position with low amplitude electrogram Lead dislodgment: low amplitude electrogram Lead malfunction: insulation defect or partial fracture Hyperkalemia, severe metabolic disturbance and toxic effects of antiarrhythmic drugs Transient undersensing after cardioversion or defibrillation Chronic fibrosis and scarring around the electrode Signal attenuation with the passage of time Development of new bundle branch block Myocardial infarction near the electrode Electronic component failure (rare) Jammed magnetic reed switch (rare) Interference with reversion to the noise-reversion asynchronous rate Attenuation of adequate cardiac signal upon entry in the pacing system: mismatch between input and source impedance (e.g. combination of large surface area electrode with low input impedance pulse generator (rare with contemporary pacemakers)

*Ventricular pseudofusion beats should not be mistaken for undersensing.

Reminder: Occasionally undersensing with a small bipolar signal can be corrected by programming to unipolar sensing. Do not expect an appropriately programmed pacemaker to sense all kinds of VPCs because they are associated with a variety of electrograms some of which may not be sensed because of a low amplitude and/or slow slew rate. Attempting to increase sensitivity to sense all VPCs may cause oversensing.

Apparent atrial undersensing in dual chamber pacing (functional atrial undersensing)

True atrial undersensing is an important cause of prolongation of the interval from AS to VS beyond the programmed AV delay. Barring true atrial undersensing from a low voltage atrial electrogram, the causes of lack of atrial tracking include the following.

1. Ventricular oversensing during the AV delay.
2. Long or extended *PVARP*. In the presence of a large atrial electrogram, a P wave may be forced into an excessively long *PVARP* sometimes due to automatic extension initiated by a pacemaker-defined VPC. If the patient's PR interval is quite long and the spontaneous rate is relatively fast, there is a greater likelihood that a P wave will fall closer to the preceding QRS complex and therefore in the *PVARP*, which need not be unduly long to cause "functional" atrial undersensing.
3. Upper rate response (preempted Wenckebach upper rate response). Prolongation of the AS-VS interval may result from failure of delivery of the ventricular stimulus if the *URI* has not timed out by the time the *AVI* has terminated. In this situation the interval between 2 consecutive QRS complexes must be shorter than the *URI* of the pulse generator.
4. Short but reinitiated *PVARP*. If the ventricular channel senses a signal other than the QRS (e.g. T wave), the *PVARP* is reinitiated by the oversensed signal and the P wave may fall in this new *PVARP*. In this situation, P wave sensing may be restored by decreasing the sensitivity of the ventricular channel.

Reminder: What looks like atrial undersensing may be functional atrial undersensing when associated with a large atrial signal.

Table 11. Causes of oversensing intracorporeal voltages.

Ventricular oversensing	T wave Afterpotential P wave (rare) Crosstalk: sensing of atrial stimulus Myopotentials False signals Triboelectric signals (static) in unipolar devices
Atrial oversensing	Far-field R wave (VA crosstalk) Myopotentials False signals Ventricular T wave (rare) Triboelectric signals (static) in unipolar devices

Afterpotential

The cathodal pacemaker stimulus charges the electrode–tissue interface to a large voltage (polarization voltage) that is subsequently dissipated over a relatively long time to electrical neutrality. The decay of the afterpotential (of lower amplitude, opposite polarity but longer duration than the output stimulus) creates a voltage that changes with time and thus it can be sensed (similarly to a changing spontaneous intracardiac signal) by a pacemaker coming out of its refractory period, when it will reset the lower rate interval. Sensing of the afterpotential should be suspected when the interval between two consecutive pacemaker stimuli lengthens to a value approximately equal to the sum of the lower rate interval and the pacemaker refractory period. This form of oversensing is now rare and is easily controlled by prolonging the refractory period or decreasing the output or the sensitivity.

False signals (voltage transients)

Abrupt changes in the resistance within a pacing system can produce large voltage changes between the poles used for pacing. Such signals are called false signals. False signals are almost always invisible on the surface ECG so that their presence must be assumed until they are revealed by a telemetered ventricular electrogram. Such "make-break" signals may occur with intermittent derangement of a pacemaker circuit from loose connections, wire fracture with otherwise well-apposed ends, insulation defect, short circuits, poorly designed active fixation leads or the interaction of two leads in the heart (one active, the other inactive) lying side by side and touching each other intermittently. Oversensing of false signals from a defective lead can cause erratic pacemaker behavior with pauses of varying duration. False signals often occur at random and can be demonstrated in the telemetered ventricular electrogram, often as large and irregular voltage deflections.

Remember that oversensing can be associated with undersensing, because the ventricular refractory period generated by a sensed false signal may contain a spontaneous QRS complex. This mixture of disturbances and the constantly changing pauses often create a chaotic pattern of pacing that is characteristic of a lead problem and must not be misinterpreted as pacemaker component failure. The characteristic pattern of false signals usually permits the exclusion of P wave oversensing (rare), T wave oversensing and/or afterpotential oversensing, which can be identified by more regular manifestations. The telemetered ventricular electrogram can be diagnostic when oversensing of false signals (potentially serious) mimics T wave sensing (less serious as it causes only bradycardia).

Reminder: If false signals causing oversensing are suspected, move the pacemaker around in its pocket and evaluate the effect of deep respiration, arm movement and changes in position to unmask an extravascular lead problem such an intermittent fracture. The lead impedance can be normal if the fracture is intermittent.

Myopotentials

Myopotentials represent electrical activity originating from skeletal muscles. A unipolar ventricular pacemaker may sense such myopotentials and cause ventricular inhibition. In a DDD pacemaker myopotentials sensed only by the atrial channel can be tracked and cause an increase in the ventricular pacing rate. Various maneuvers can bring out this interference during follow-up evaluation. This disturbance can often be controlled by a reduction in sensitivity or by programming to the bipolar mode if this is feasible.

Caveat: Lack of ventricular pacing during provocative maneuvers for myopotential oversensing may be the result of myopotential inhibition (oversensing), but may sometimes be caused by an intermittent lead fracture that has become manifest during the testing procedure.

Pacemaker response to oversensing interference

Pacemakers can be inhibited by low frequency interference which is uncommon. Pacemakers are designed to respond to rapidly occurring (high frequency) extraneous signals by reverting temporarily to the protective asynchronous mode (interference mode) functioning usually at the programmed lower rate. A signal sensed in the unblanked portion of the ventricular refractory period (*VRP*) or in a part thereof (specifically called the noise sampling period) reinitiates a new *VRP* or noise sampling period respectively. This process repeats itself with each detected signal so that the "overlapping" effect of these special timing cycles prevents the initiation of a lower rate interval because the entire pacemaker cycle consists of *VRP* or noise sampling periods. This repeated reinitiation or overlapping effect assures the delivery of a pacemaker stimulus at the interference rate. The pacemaker returns to its normal operating mode when noise is no longer detected.

Follow-up of lead impedance

The lead is the weakest link in the pacing system. Lead impedance tends to fall in the first 2 weeks after implantation but then reaches a plateau and remains relatively stable at approximately 15% higher than the implantation value. Some pacemakers automatically track the impedance over time by making periodic measurements. The trend data can be retrieved by standard pacemaker interrogation. Fluctuations of impedance by as much as 300 Ω are often considered normal. Such a change in an asymptomatic patient, however, warrants closer follow-up.

Reminder: A magnet over an ICD eliminates its antitachycardia function but does not convert it to asynchronous pacing.

Table 12. Causes of changes in pacing rate.

Normal function	Application of the magnet Inaccurate speed of ECG machine Apparent malfunction in special situations such as hysteresis, sleep rate Reversion to interference rate in response to electromagnetic interference if the noise reversion rate differs from the programmed lower rate
Abnormal function	Battery depletion with slowing of the rate Runaway pacemaker Component failure Permanent or temporary change in mode after electrocautery, therapeutic radiation, or defibrillation Phantom reprogramming (done without documentation) or misprogramming Oversensing (e.g. T wave sensing) Crosstalk resulting with ventricular safety pacing causing an increase in the pacing rate

Table 13. Manifestations of lead fracture.

- No stimuli because of an open circuit (markers may show normal emission of stimulus)
- Stimuli without capture
- Oversensing of false signals; the false signals are invisible on the ECG but can be demonstrated by telemetry of event markers and electrograms
- Oversensing can cause undersensing; occasionally the sensed signal itself can be attenuated
- Telemetry showing an abnormally high lead impedance, but the value can be normal if the fracture is intermittent or there is a concomitant insulation break
- Maneuvers: if suspected, one should apply pressure along the course of the subcutaneous portion of the lead, extend the arm on the side of the pacemaker, place the arm behind the back, and rotate the shoulder backward to unmask a crush injury due to clavicle–first rib compression
- A fracture may or may not be detectable on a radiograph

Table 14. Manifestations of insulation defect.

- Extracardiac muscle stimulation if the defect is extravascular (twitching)
- Pacing may be preserved but loss of capture can occur when a large current is shunted from the electrodes; an insulation defect accelerates battery depletion
- Undersensing from signal attenuation
- Oversensing of false signals; oversensing can cause undersensing
- False signals are invisible on the ECG but telemetry with annotated markers can demonstrate false signals on the electrogram (also programming in the AAT or VVT mode may be of help)
- Telemetry shows an abnormally low lead impedance, but the value can be normal if the insulation defect is intermittent
- The insulation is radiolucent and abnormalities cannot be detected on a radiograph

Table 15. Presence of an atrial stimulus but no ventricular stimulus during DDD or DDDR pacing.

1. Atrial pacing followed by a conducted QRS complex before completion of the AV delay; apply the magnet for diagnosis
2. Isoelectric or tiny ventricular stimuli; use double standardization of the ECG machine
3. Concealed ventricular stimuli within the QRS complex (pseudofusion); marker channel confirms diagnosis
4. Disconnection of the ventricular circuit as in a lead fracture; this causes apparent AAI pacing; reprogram to the VVI mode whereupon no stimuli will be seen in the VVI and VOO (magnet) modes
5. Crosstalk in devices *without* ventricular safety pacing; application of the magnet confirms diagnosis
6. Oversensing during the AV delay; apply magnet; use telemetry to demonstrate the electrogram and annotated markers

Table 16. Presence of ventricular stimulus but no atrial stimulus during DDD or DDDR pacing.

1. In some devices, magnet application causes VOO pacing
2. Disconnection of the atrial circuit: VVI pacing in the DDD mode and no stimulation the AAI and AOO modes
3. Isoelectric or tiny atrial stimuli; use double standardization of the ECG machine
4. Concealed atrial stimuli within the QRS complex (pseudopseudofusion); use marker channel for diagnosis
5. DDI mode when the atrial channel is continually inhibited; apply magnet for diagnosis
6. Apparent VVI pacing: the atrial stimulus (occasionally because of atrial undersensing) is coincident with the onset of the spontaneous QRS complex with a left bundle branch block configuration

Table 17. Pacemaker magnet application.

1. Conversion to the asynchronous mode; VOO or DOO according to programmed mode
2. Assess capture during asynchronous pacing
3. Elective replacement indicator
4. Provides reed switch activation as required for some programmers to function
5. Eliminates sensing; useful during electrocautery; provides diagnosis of oversensing
6. Patient can trigger electrogram storage during symptomatic episode
7. Termination of endless loop tachycardia
8. Competitive underdrive pacing for the termination of some reentrant tachycardias
9. May help identification of device as some have typical magnet response

Table 18. Data required in pacemaker chart.

Patient data	Name, age, address, phone number, etc.
Pacemaker data	Date of implantation
	Model and serial number of leads
	Model and serial number of pulse generator
Data form implantation	Pacing threshold(s)
	Sensing threshold(s)
	Intracardiac electrograms
	Lead impedance(s)
	Status of retrograde VA conduction
	Presence of diaphragmatic or accessory muscle stimulation with 5 and 10 V output
Technical specifications	Pacemaker behavior in the magnet mode
	Record of elective replacement indicator: magnet and/or free running rate, mode change, telemetered battery data (impedance and voltage)
Data from pacemaker clinic	Programmed parameters from time of implantation and most recent changes
	12-lead ECG and long rhythm strips showing pacing and inhibition of pacing to evaluate underlying rhythm
	12-lead ECG upon application of the magnet
	Electronic rate intervals and pulse duration measured with a special monitor
	Interrogation and printout of telemetric data
	Always print a copy of the initial interrogation and measured data.
Systematic evaluation of pacing system	Atrial and ventricular pacing and sensing thresholds
	Retrograde VA conduction and propensity to endless loop tachycardia
	Evaluation of crosstalk
	Myopotential interference (record best way of reproducing abnormality)
	Special features: automatic mode switching parameters, ventricular safety pacing, noncompetitive atrial pacing, etc.
	Evaluation of sensor function with exercise protocols, histograms and other data to demonstrate heart rate response in the rate-adaptive mode
	Final telemetry printout at end of evaluation and date. Check that any changes in parameters are intentional by comparing the final parameters with those obtained at the time of initial pacemaker interrogation. Any discrepancy must be justified in the record.
Ancillary data	Symptoms and potential pacemaker problems
	ECG with event markers and electrograms mounted in the chart
	Intolerance of VOO pacing upon application of the magnet

Table 19. Causes of increased battery current drain affecting battery longevity. This is the most important determinant of battery longevity (expressed in A). Pacing requires more current than sensing.

1. The greater the % pacing, the shorter the longevity
2. Increase in the pacing rate (cycle length).
3. Increase in output voltage
4. Increase in pulse duration
5. Change from single chamber to dual chamber mode
6. Use of rate-adaptive function with nonatrial sensor
7. Decrease in lead impedance
8. Programming, telemetering, storage of diagnostics

Impedance while not programmable, can be controlled by selecting a high impedance lead at the time of implantation.

Pacemaker longevity can be enhanced by careful programming and selecting steroid-eluting leads with a small radius tip electrode (small surface area for stimulation) that provide low thresholds and efficient high impedance (over 1000 Ω). The high impedance is at the electrode–tissue level where the maximum voltage is available at the electrode tip for stimulation. The high impedance reduces current drain from the battery by Ohm's law. Thus, ideally one should implant small surface area, steroid eluting and porous electrodes. The porosity creates a complex surface structure which increases the effective surface area for sensing and improves the efficiency of sensing.

Caveat: Do not confuse battery current drain with current output (mA) at the electrode–myocardial interface with delivery of the pacemaker pulse. When trying to conserve battery life, monitor the battery current drain as you program various parameters.

Caveat: From the elective replacement indicator (ERI) point, a pacemaker will reach end-of-life (EOL) or end-of-service (EOS) in about 3 months. At EOL pacing becomes erratic and unreliable with the possibility of total system failure.

Table 20. Elective replacement indicator (ERI) vs. reset situation. Differential diagnosis when the mode of operation is identical.

The reset mode, usually VVI or VOO, represents a normal protective response to high intensity electromagnetic interference. A reset pacemaker does not represent malfunction and it can easily be reprogrammed to its previous mode.

The backup pacing circuit of certain DDD pacemakers can produce a similar situation when activated by low battery voltage as a mechanism to reduce the current requirement from the battery

1. In ERI (or recommended replacement time – RRT), the battery voltage is low and the battery impedance is high. The ERI point is manufacturer-defined. Note that when the battery voltage of a dual chamber pacemaker reaches ERI, switching to the VVI mode automatically increases the battery voltage to a higher level than the specified ERI point. In reset, the battery voltage is high and the battery impedance has not yet reached the ERI point
2. Battery stress test: program the pacemaker to dual chamber mode at a relatively fast rate and high output and watch for a while. If the pacemaker continues to function normally, the diagnosis was reset. If it switches back to VVI the diagnosis was ERI

Automatic mode switching

In the past, paroxysmal atrial arrhythmias constituted a contraindication to dual chamber pacing. Advances in pacemaker technology have now made it possible to use dual chamber pacemakers safely in this patient population. Dual chamber pacemakers equipped with automatic mode switching (AMS) can now protect the patient from rapid ventricular pacing by automatically functioning in a nonatrial tracking mode (VVI, VVIR, DDI, DDIR) during supraventricular tachycardia. AMS requires fundamental changes in the operation of pacemaker timing cycles to maximize

supraventricular tachycardia detection above the programmed upper rate. Although many of the AMS algorithms from a variety of manufacturers are device-specific, the timing cycles required for supraventricular tachycardia detection are basically independent of AMS algorithm design. For appropriate supraventricular tachycardia detection the atrial signal should be of sufficient amplitude and the obligatory blanking periods (when the sensing amplifier is temporarily disabled), should be restricted to a small fraction of the pacing cycle. Blanking periods cannot be eliminated because they prevent oversensing of undesirable signals inherent to all pacing systems.

VA crosstalk

The atrial channel cannot sense a signal associated with the ventricular stimulus because the atrial channel of all pacemakers is blinded or blanked by the relatively long postventricular atrial blanking that starts coincidentally with emission of the ventricular stimulus. Ventriculoatrial (VA) or reverse crosstalk refers to far-field sensing that occurs when ventricular signals in the atrial electrogram are sensed by the atrial channel in the *PVARP* beyond the postventricular atrial blanking period (sensing the paced QRS complex) or in the unblanked terminal portion of the AV delay (sensing the spontaneous QRS complex). VA crosstalk occurs because the smaller atrial electrograms during supraventricular tachycardia require programming a higher atrial sensitivity for sensing than those needed to sense the normal rhythm. VA crosstalk can often be eliminated by reducing atrial sensitivity but this carries the risk of atrial undersensing during supraventricular tachycardia when atrial signals become smaller. Far-field atrial sensing may be reduced by the use of bipolar sensing and improved pulse generator and lead technology.

Caveat: Detection of smaller signals during atrial tachyarrhythmias requires a high atrial sensitivity, which predisposes to VA crosstalk.

Timing cycles related to automatic mode switching

The unblanked portion of the *AVI* (initiated by a paced or sensed atrial event) was designed to enhance sensing of atrial fibrillation during the *AVI* to facilitate AMS. A ventricular paced or sensed event initiates the postventricular atrial refractory period (*PVARP*), the first portion of which is the postventricular atrial blanking period (*PVAB*). The second part of the *PVARP* is unblanked (*PVARP*-U) but sensing within it cannot initiate an AV delay. The *PVARP* initiated by ventricular pacing is almost always equal to the *PVARP* initiated by ventricular sensing. Far-field sensing within the *PVARP* can be corrected by programming lower atrial sensitivity or the *PAVB* to a longer value. Programmability of the *PVAB* is a relatively new feature of pacemakers. A long *PVAB* predisposes to atrial undersensing of supraventricular tachycardia crucial for AMS activation. Sensing of supraventricular tachycardia for AMS function is therefore possible during the unblanked refractory periods (*AVI-U* and *PVARP-U*) as well as during the cycle without atrial refractory periods where atrial sensing initiates an AV delay.

Retriggerable atrial refractory period

Some pacemakers work with an atrial refractory period that can be retriggered or reset by reverting to the DVI or DVIR mode upon sensing a fast atrial rate. In such a system, an atrial signal detected in the *PVARP* beyond the initial *PVAB* does not start an *AVI* but reinitiates a new total atrial refractory period (*TARP*) or the sum of *AVI* and *PVARP*. This process repeats itself so that supraventricular tachycardia faster than the programmed upper rate (i.e. P–P interval <*TARP*) automatically converts the atrial channel to the asynchronous mode and the pacemaker to the DVI mode at the lower rate or the DVIR mode according to design and programmability.

Reminder: The concept of overlapping refractory periods is also important in the ventricular channel of pacemakers to prevent continuous inhibition from rapidly recurring extraneous signals from interference.

Testing for VA crosstalk

The propensity for VA crosstalk during the *PVARP* should be tested during ventricular pacing. The AS–VP interval is shortened to permit continual ventricular capture. The pacemaker is then programmed to the highest atrial sensitivity and the largest ventricular output (voltage and pulse duration). These settings should be evaluated at several pacing rates to at least 110–120 p.p.m. because faster ventricular pacing rates impair dissipation of the afterpotential or polarization voltage at the electrode–myocardial interface. Such parameters enhance the afterpotential and therefore generate a voltage superimposed on the tail end of the paced QRS complex. The combined voltage from these two sources may be sensed as a far-field signal by the atrial channel. VA crosstalk can be eliminated by decreasing atrial sensitivity provided one knows that the atrial signals

during supraventricular tachycardia can be sensed at the lower sensitivity. In devices with a programmable *PAVB*, the testing procedure if positive for VA crosstalk can be performed at various durations of the *PVAB* until VA crosstalk is eliminated. VA crosstalk within the *AVI* is evaluated by programming a low lower rate and long *AVI* to promote spontaneous sinus rhythm and AV conduction.

Detection of atrial flutter by dual chamber pacemakers

In some designs, the duration of the blanking periods prevents the pacemaker from detecting atrial flutter, if the atrial cycle does not match the sensing window of the atrial channel. In other words, the duration of the *PVAB* imposes mathematical limits on the detection of atrial flutter. If *AVI* + *PVAB* > atrial cycle length (P–P or f–f interval), the pacemaker will exhibit 2:1 atrial sensing of atrial flutter (2:1 lockout). Sensing of alternate atrial signals will occur if *AVI* + *PVARP* < 2 atrial cycles. Abbreviation of the *PVAB* may solve the problem if far-field R wave sensing does not occur. If *PVAB* is nonprogrammable, restoration of 1:1 atrial sensing would require programming of the *AVI* to very short durations such as 50 ms. Restoration of AMS function by shortening of the *AVI* to circumvent a fixed *PVAB*, produces unfavorable hemodynamics for long-term pacing if the *AVI* remains permanently short in the absence of supraventricular tachycardia.

The detection of atrial signals can be ameliorated by reducing the blanked *AVI*. Thus, a design that allows substantial shortening of the AS–VP interval only with increasing sensed atrial rates, optimizes sensing of atrial flutter, and yet preserves a physiologic *AVI* at rest and low levels of exercise. During supraventricular tachycardia when (AS–VP interval) + *PVAB* = 30 + 150 = 180 ms this combination allows sensing of atrial flutter with a cycle length up to 180 ms (rate = 333/min). Another algorithm specifically designed for atrial flutter, automatically extends the *PVARP* for one cycle whenever the pacemaker detects an atrial cycle length less than twice (*AVI* + *PVAB*) and the atrial rate is greater than half the tachycardia detection rate (or the atrial interval is less than twice the tachycardia detection interval). AMS occurs if an atrial event is sensed within the extended *PVARP* thereby revealing the true atrial cycle.

Caveat: Troubleshooting automatic mode switching requires knowledge of the algorithm, blanking periods and atrial signal in sinus rhythm and atrial sensitivity.

Pacemaker follow-up

The frequency and type of follow-up depend on the projected battery life, type, mode, and programming of pacemakers, the stability of pacing and sensing, the need for programming change, the underlying rhythm (pacemaker dependency), travel logistics, type of third party insurance and alternative methods of follow-up such as the telephone. Most centers follow the Medicare guidelines for pacemaker follow-up (i.e. for single chamber pacemakers: twice during the first 6 months after implant and then once every 12 months; for dual chamber pacemakers: twice during the first 6 months after implant and then once every 6 months). Transtelephonic monitoring is recommended as part of a comprehensive and cost-effective pacemaker patient management program. Telephone follow-up is designed to supplement periodic visits to the pacemaker center and should not replace comprehensive follow-up. It provides early detection of device-related complications. As a rule, transtelephonic follow-up from the convenience of the patient's home does not allow programming and transmission of telemetry data though the latter may soon become possible via the Internet. Medicare guidelines have also been published for telephone follow-up. A typical transtelephonic test takes approximately 15 min. Patients use a simple device that transmits useful information regarding the basic functional capabilities of the pacemaker.

Holter recordings in pacemaker follow-up

Holter monitoring is useful in the investigation of unexplained symptoms such as syncope, dizziness and palpitations. In *routine* Holter recordings the commonest abnormalities consist of atrial undersensing and myopotential interference in unipolar systems. The interpretation of recordings from DDD pacemakers may be difficult or impossible because of various pauses, apparent shortening of intervals, or missing or concealed stimuli. A system that enhances the pacemaker stimulus (and displays it in a separate channel) may be very useful. However, such a system may generate electrostatic discharges that produce deflections from loose electrodes, etc., resembling pacemaker stimuli. Spurious pacemaker stimuli should not be misinterpreted as pacemaker malfunction.

The pacemaker as an implantable Holter system

Histograms cannot separate events or determine when they occur. However, histograms are useful to evaluate the programmed sensor response provided there is a breakdown of the heart rates into ranges. Histograms may also enhance programmability of the *AVI*. Intermittent atrial fibrillation should be suspected if an atrial histogram shows a high rate event. It is questionable whether marker annotations alone stored in pacemaker memory are useful in assessing the number and duration of arrhythmic episodes. The recent development of electrogram storage and retrieval by pacemakers (available for some time in ICDs) has added a new dimension to the diagnosis of spontaneous arrhythmias and device malfunction in patients with pacemakers. Pacemakers store the data either automatically according to a detection algorithm or by a patient-activated system whenever a symptomatic patient applies a magnet or a special activator over the device. Annotated high-quality electrograms allow reliable assessment of stored episodes by visual inspection in practically 100% of cases. The final diagnosis of the retrieved data scrutinized by the physician may, of course, differ from the automatic interpretation by detection algorithm of the device. Detection algorithms for the detection of supraventricular tachyarrhythmias are further developed than those for ventricular tachyarrhythmias which are still rudimentary.

The electrogram must be sampled at twice the minimal frequency component to register all the information contained in it. Sampling at 256 samples/s allows good reproduction and a minimum rate of 128 samples/s is necessary to achieve a sufficiently diagnostic EGM quality. One byte of memory is generally required for each sample. Assuming a pacemaker with 8 K of memory dedicated to EGM recording, and a sampling rate of 128 samples/s, the duration of (uncompressed) single channel EGM recording is 8 K × 1024 bytes/K ÷ 128 bytes/s which is equal to 64 s. Compression algorithms can increase this duration further because repeated sequences such as the baseline can be stored using far less memory. Thus the 64 s in the previous example can be expanded to 320 s with 5:1 average compression yielding 320 s of EGM storage.

Pacemaker technology can now store electrograms with the following features:

1. separate channels for atrial and ventricular EGMs of sufficient resolution and duration;
2. onset and termination data: a programmable number of cardiac cycles before arrhythmia onset ("pre-trigger EGM") and some cycles after arrhythmia termination;
3. simultaneous annotated markers (essential); marker annotations and intervals to facilitate understanding why and how the pacemaker detected and classified an event. An additional marker annotation (e.g. arrow, line) should indicate the exact moment when arrhythmia detection criteria are fulfilled.

The memory capability of modern pacemakers promises to improve our understanding of a variety of electrophysiologic mechanisms that will enhance the diagnosis and treatment of atrial and ventricular tachyarrhythmias. The memory function will be especially useful to optimize programming of increasingly complex devices.

What is cardiac resynchronization?

Cardiac resynchronization refers to stimulation techniques that improve the degree of atrial and/or ventricular electrical dyssynchrony in patients with major (intra- or inter-) atrial and/or ventricular conduction disorders. The latter includes left bundle branch block and the interventricular conduction delay induced by conventional RV pacemakers. Resynchronization produces beneficial hemodynamic effects because of a more physiologic or effective pattern of depolarization. For example, in the treatment of congestive heart failure with dilated cardiomyopathy and left bundle branch block, the change in electrical activation from resynchronization (with biventricular pacing), which has no positive inotropic effect as such, is translated into mechanical improvement with a more coordinated ventricular contraction.

Atrial resynchronization

Multisite atrial resynchronization was introduced for the treatment of severe interatrial conduction delay in patients with sick sinus syndrome and/or paroxysmal atrial fibrillation. Interatrial conduction delay can usually be diagnosed from the ECG in the presence of P waves > 120 ms. Hemodynamically, the delay of electrical activation from a single pacing site in the right atrium to the left atrium may not produce an optimal mechanical AV delay on the left side of the heart. Thus, conventional right atrial pacing may generate left atrial systole too close to or during ventricular systole with the resultant loss of effective atrial contribution. Additionally atrial resynchronization may prevent paroxysmal atrial fibrillation in selected patients. Atrial resynchronization can be achieved with simultaneous (biatrial)

pacing from the right atrial appendage and the left atrium (via the coronary sinus), or a bifocal system involving simultaneous atrial pacing from the right atrial appendage and the atrial septum very close to the coronary sinus os.

Dilated cardiomyopathy and congestive heart failure: ventricular resynchronization

Dual site or biventricular (RV and LV) pacing has emerged as an effective therapy for patients with dilated cardiomyopathy (severe systolic LV dysfunction) and congestive heart failure associated with major left-sided intraventricular conduction delay such as left bundle branch block. This intraventricular conduction disorder causes an inefficient dyssynchronous or uncoordinated pattern of LV activation with segments contracting at different times with a characteristic wobble of the interventricular septum. The erratic LV contraction causes a shorter diastole and/or overlapping systole/diastole with aggravation of functional mitral regurgitation. Biventricular pacing works by reducing the degree of electromechanical disparity. Thus, the improved sequence of electrical activation (a process known as resynchronization) translates into beneficial acute and long-term hemodynamic effects by virtue of a more coordinated and efficient LV contraction associated with a reduction of functional mitral regurgitation. The hemodynamic benefit occurs virtually with an on/off effect (with possible long-term reverse remodeling of the LV) and stems primarily from ventricular recoordination rather than optimization of the AV delay. A recent study suggests that this therapy may also reduce mortality. An optimized AV delay is important but it is not the major factor for improvement in most patients. The proper site of LV stimulation (best in the lateral or posterolateral area) is the most important determinant of a successful hemodynamic response. Some hemodynamic benefit may be obtained by programming the V–V interval (interval between RV and LV stimulation) available in second-generation biventricular pacemakers under echocardiographic control. The LV usually has to be programmed ahead of the RV.

The clinical value of resynchronization with biventricular stimulation has now been established for ≥ 2 years in clinical trials. The functional benefit of resynchronization is sustained over time. However about 20–30% of patients are nonresponders. Patients with idiopathic cardiomyopathy respond better than those with coronary artery disease. In general, long-term resynchronization improves the systolic blood pressure, cardiac output, LV ejection fraction (3–5%) and reduces mitral regurgitation (about 50%). Patients with permanent atrial fibrillation benefit from resynchronization to a lesser degree than those in sinus rhythm. With atrial fibrillation, RF ablation of the AV junction is necessary to ensure continual ventricular depolarization by the biventricular system.

Indications for biventricular pacing (cardiac resynchronization)

Patients with a QRS duration > 150 ms are more likely to improve than those with a QRS between 120 and 150 ms. In a given patient, however, the precise QRS duration is not always predictive of benefit. Biventricular pacing should be considered in medically refractory symptomatic New York Heart Association class III or IV patients with idiopathic dilated or ischemic cardiomyopathy, prolonged QRS (≥ 130 ms), LV end-diastolic diameter ≥ 55 mm (on the echocardiogram), and LV ejection fraction ≤ 35%. Patients with systolic congestive heart failure and a previously implanted RV pacemaker (with a very wide paced QRS complex) are also candidates for biventricular pacing.

Complications

Complications of biventricular pacing include lead dislodgment (5–10%), high pacing threshold (of LV pacing), acute cardiac tamponade from coronary sinus dissection (though dissection is often benign) and phrenic nerve stimulation (causing disturbing diaphragmatic contractions), which can be a major problem. The long duration of the implantation procedure is associated with a higher rate of pocket infection. First generation devices with simultaneous sensing from both ventricles may exhibit special problems, such as double sensing of the QRS complex and oversensing of the P wave by the LV lead (usually because of displacement towards the left atrium) as discussed later.

Electrocardiography

A baseline 12-lead ECG should be recorded at the time of implantation during assessment of the independent capture thresholds of the RV and LV to identify the specific morphology of the paced QRS complexes in a multiplicity of leads. This requires having the patient connected to a multichannel 12-lead ECG during the implantation procedure. A total of four 12-lead ECGs are required:

1. intrinsic rhythm and QRS complex before any pacing;
2. paced QRS associated with RV pacing;

3. paced QRS associated with LV pacing;
4. paced QRS associated with biventricular pacing.

The four tracings should be examined to identify the lead configuration that best demonstrates a discernible and obvious difference between the four pacing states (inhibited, RV only, LV only, and biventricular). This ECG lead should then be used as the surface monitoring lead for subsequent evaluations. Loss of capture in one ventricle will cause a change in the morphology of ventricular paced beats in the 12-lead ECG to that of either single chamber RV pacing or single chamber LV pacing. When there is intact capture in both the RV and LV, the evoked response on the ventricular electrogram will show a monophasic complex in contrast to two distinct deflections (RV and LV electrograms) during spontaneous conduction if the native QRS is wide (left intraventricular conduction delay). With loss of capture in one of the ventricles, the ventricular lead which is still effective will cause a depolarization of that ventricle. The impulse will then have to be conducted via the native pathways to the other ventricle in an manner identical to single ventricular systems with standard pacing. If RV pacing is preserved and there is failure of LV capture associated with a significant left intraventricular conduction delay, the ventricular electrogram will change from a monophasic complex to one showing one relatively late and discrete deflection (electrogram) representing late activation of the LV. A shift in the frontal plane axis may be useful to corroborate the loss of capture.

Reminder: A qR or Qr complex in lead I is rare in uncomplicated RV apical pacing. It is present in 90% of cases of biventricular pacing. In biventricular pacing, loss of the q or Q wave in lead I is 100% predictive of loss of LV capture.

The preempted Wenckebach upper rate response

In a traditional Wenckebach upper rate response, a dual chamber pacemaker (where upper rate interval > total atrial refractory period) delivers its ventricular stimulus only at the completion of the (atria-driven) upper rate interval. The AV delay initiated by a sensed P wave increases progressively because the ventricular channel waits to deliver its output at the end of the upper rate interval. Eventually a P wave falls in the *PVARP*, a pause occurs and the ventricular *paced* sequence repeats itself. In patients with pacemakers implanted for congestive heart failure, the Wenckebach upper rate response (or more precisely the manifestation of upper rate > total atrial refractory period) assumes a form that is not immediately recognizable because no paced beats are evident.

In patients with normal or near normal sinus node function and AV conduction, a pacemaker Wenckebach upper rate response takes the form of a repetitive preempted process which consists of an attempted Wenckebach upper rate response with each cycle, associated with continual *partial* or *incomplete* extension of the programmed *AVI*. The conducted spontaneous QRS complex continually occurs before completion of the upper rate interval. It is therefore sensed by the pacemaker, and ventricular pacing is preempted. In other words, the pacemaker cannot time out the upper rate interval and thus cannot emit a ventricular stimulus at its completion. This form of upper rate response tends to occur in patients with relatively normal AV conduction, a short programmed AV delay, a relatively slow programmed (atrial-driven) upper rate, and a sinus rate faster than the programmed (atrial-driven) upper rate. It is therefore more likely to emerge on exercise or during times of distress when adrenergic tone is high. Consequently the preempted Wenckebach upper rate response has become important recently because pacemakers are now implanted in patients with congestive heart failure (or hypertrophic cardiomyopathy) where there is usually relatively normal sinus node function and AV conduction. The occurrence of a preempted Wenckebach response in such patients defeats the very purpose of this type of cardiac stimulation. Hence, in patients with congestive heart failure susceptible to sinus tachycardia (despite beta-blocker therapy and especially during decompensation), it is important to program a relatively fast upper rate during biventricular pacing to avoid a preempted Wenckebach upper rate response with resultant loss of cardiac resynchronization manifested by the emergence of the patient's own QRS in the electrocardiogram.

In summary, a preempted Wenckebach upper rate response has *no paced events* and is characterized by four features:

1. VS–VS interval < atrial-driven upper rate interval (VS = ventricular sensed event);
2. PR interval (AS–VS) > programmed AS–VP. The spontaneous PR interval remains relatively constant (AP, atrial paced event; AS, atrial sensed event);
3. There are no unsensed (or refractory sensed) P waves as in a typical Wenckebach upper rate response in the presence of AV block;
4. P wave tracking will not be restored until the atrial cycle length exceeds the duration of the intrinsic total atrial refractory period (intrinsic *PR* + *PVARP*).

Caveats:

1. Patients with congestive heart failure and no bradycardia may develop sinus tachycardia under certain circumstances. Therefore the upper rate of biventricular pacemakers should be relatively fast to avoid a preempted Wenckebach response that desynchronizes the heart and withholds beneficial biventricular pacing.
2. If the upper rate is programmed too low in a patient with angina pectoris, loss of ventricular resynchronization on exercise may actually precipitate angina. Such patients usually do better with a higher upper rate to permit ventricular resynchronization and improved cardiac efficiency during activity.

Double counting of the ventricular electrogram

In first generation biventricular systems, the pacemaker paces and senses from the two ventricles simultaneously. Double counting of the ventricular complex involves the spontaneous conducted wide QRS complex of left bundle branch block (as most patients do not have AV block). This situation produces temporal separation of right ventricular (RV) and left ventricular (LV) electrograms. The degree of separation depends on the severity of the interventricular conduction delay (left bundle branch block) and the location of the electrodes. The LV electrogram may therefore be sensed some time after detection of the RV electrogram if the LV signal extends beyond the relatively short ventricular blanking period initiated by RV sensing. With ventricular rhythms, the LV electrogram may precede that from the RV. Double counting in first generation biventricular cardioverter-defibrillators (sensing both RV and LV simultaneously) may cause inappropriate shocks. Second generation devices allow programming of the sensing function of the ventricular channels individually to prevent double counting (RV and LV electrograms).

The circumstances leading to the emergence of the spontaneous QRS complex and the perpetuation of double QRS counting must be understood because it prevents the delivery of therapeutic biventricular stimulation and the problem can often be corrected by appropriate programming of the pacemaker. The main causes are a long *PVARP* (that may be extended after a VPC) which pushes the sinus P in the *PVARP* (refractory sensed) where it cannot initiate an AV delay and sinus tachycardia above the programmed upper rate. When the sinus rate increases beyond the programmed upper rate, spontaneous AV conduction occurs in the form of a preempted Wenckebach upper rate response and therapeutic biventricular pacing is inhibited. Hence the importance of programming a relatively fast upper rate to prevent this process. Supraventricular and ventricular tachycardias also cause double counting, but their impact is more important in biventricular cardioverter-defibrillators when double counting may cause the delivery of an inappropriate shock.

Table 21. How to ensure biventricular pacing in a rst generation dual chamber system with a dual cathodal system (simultaneous pacing and sensing in both ventricles).

1. Low ventricular sensitivity to prevent oversensing of far-field left atrial activity
2. High output (at least initially) to ensure LV pacing
3. Program a high upper rate to prevent a preempted Wenckebach upper rate response. Programming a relatively slow rate to control angina may be counterproductive
4. Program appropriate rate-adaptive AV delay
5. Program a relatively short *PVARP*:
   (a) this may require using the "PMT" intervention function on in case the patient is prone to endless loop tachycardia
   (b) program off the *PVARP* extension response to a VPC
   (c) turn off automatic mode switching in pacemakers requiring a relatively long *PVARP* for the algorithm
6. Treat atrial fibrillation aggressively to prevent the emergence of spontaneously conducted QRS complexes
7. Use pacemaker diagnostics for % ventricular sensing to assess efficacy of biventricular pacing
8. Consider AV junction ablation in patients with atrial fibrillation and fast ventricular rate unresponsive to beta blockers

PMT = pacemaker mediated tachycardia

Caveats:

1. Ensure the absence of ventricular fusion beats with the spontaneous QRS complex to provide the patient the full benefit of biventricular pacing. The absence of fusion is determined by observing the QRS configuration in the 12-lead ECG during gradual shortening of the AV delay.

2. During follow-up, check the memory data of the pacemaker to confirm the absence of spontaneous AV conduction.
3. Remember that the site of LV stimulation is the most important determinant of successful therapy. (The wrong site may actually aggravate heart failure.) Optimization of the AV delay provides only modest benefit but may be more important in patients with a long PR interval. New devices permit optimization of the LV–RV interval but this also provides modest benefit.

Anodal stimulation

This phenomenon may be confusing but it has no clinical importance. During bipolar ventricular pacing, cathodal and anodal capture can occur at high outputs but such anodal stimulation is not seen on the electrocardiogram. In first-generation biventricular systems, the RV lead is bipolar and the LV lead unipolar. The ring of the RV lead provides a common anode for both RV and LV pacing. The increased current density at the common anode (pacing two ventricles) may cause anodal capture in the RV when the common output is high. This causes a change in the paced ECG which disappears when biventricular pacing is performed at a lower output or as true unipolar pacing of the RV and LV using the pacemaker can as the anode. Anodal stimulation can also occur when a second-generation biventricular pacemaker is programmed to pace only the LV, whereupon anodal capture will mimic biventricular pacing.

Signi cance of the paced QRS duration

Evaluation of the paced QRS duration as an index of efficacy is simplistic and potentially misleading. It is possible to have a wide biventricular paced QRS (longer than the spontaneous QRS) with clinical improvement if the LV walls contract more homogeneously. In other words, lack of QRS shortening with biventricular pacing is not a marker for a poor clinical response. The best example of this concept is provided by unichamber LV pacing (mostly documented in acute studies), which produces significant hemodynamic improvement in the setting of a very large paced QRS complex. In other words, the electrical manifestations are of limited value in the clinical assessment. Proper evaluation of the consequences of biventricular pacing requires the use of mechanical indices by echocardiographic techniques

Far- eld sensing of atrial depolarization

An LV lead located in one of the coronary veins may sense the far-field P wave because of electrode proximity to the left atrium especially if anatomical constraints prevent placement of the lead in a desirable distal site away from the AV groove. Moreover, the higher dislocation rates of LV leads towards the AV groove increases the likelihood of sensing relatively large atrial signals from the coronary sinus. Far-field P wave sensing by a displaced lead in the coronary sinus can be devastating in pacemaker-dependent patients who have undergone ablation of the AV junction for atrial fibrillation. Far-field atrial sensing by the ventricular channel can inhibit biventricular pacing and withhold therapy for congestive heart failure.

Table 22. Indicators for far- eld P wave sensing in biventricular pacemakers.

1. Recurrence or development of symptoms of congestive heart failure
2. Inappropriately short AS–VP delay on surface ECG
3. Unexpected inhibition of ventricular output (DDD mode) with a PR interval > programmed AS–VP delay (at rates *below* the maximum tracking rate)
4. Event markers recorded with simultaneously telemetered ventricular electrogram and surface ECG

Table 23. Management of atrial far- eld P wave oversensing in biventricular pacemakers.

1. Prophylaxis: some cases of far-field P sensing may be prevented by repositioning the LV lead at the time of implantation if the LV or biventricular electrogram registers a large atrial deflection
2. Reduce ventricular sensitivity while monitoring the rhythm using the programmer, and marker channel
3. Use the DOO mode in selected cases
4. Obtain 24-h Holter monitor looking for undersensing of ventricular premature beats and competition to determine whether the reduced sensitivity should be maintained
5. If far-field sensing of the P wave cannot be eliminated by programming or reducing the sensitivity, the LV lead needs to be repositioned or the device replaced by one that senses only from the RV

Impedance measurements in first-generation biventricular pacemakers

Before totally independent programmability became available for each lead, a divided pacemaker output or common dual cathodal system (simultaneous dual site cathodal stimulation with the leads connected in parallel) was widely used. The parallel arrangement and the larger combined surface area of the right and left ventricular leads (compared to a single lead) result in a reduced stimulation impedance. Thus, the total lead impedance is likely to be low (in the range of 250–400 Ω) in a normally functioning biventricular system. A mechanical problem in one of the ventricular leads but not the other may not be readily detectable using standard impedance criteria. An open circuit (conductor fracture) involving one lead will not result in the very high impedances that are present with single chamber pacing. Rather, that lead will effectively be taken out of the system and the measured impedance will reflect the expected impedance for the intact ventricular lead. Hence, with an open circuit on one of the two ventricular leads, the measured impedance may rise to the normal range for a univentricular lead. The normally low impedance in a dual cathodal system may also complicate the diagnosis of an insulation failure in one of the leads. The low telemetered impedance that is associated with an insulation failure in a single chamber lead may be in the "normal" range during intact biventricular pacing.

Caveat: In most cases the RV pacing threshold will be lower than the LV threshold. The monochamber LV pacing threshold is not the same as the biventricular threshold.

Biventricular pacing with conventional pacemakers

Although conventional dual chamber pacemakers are not designed for biventricular pacing and generally do not allow programming of an AV delay of zero or near zero, they are being increasingly used with their shortest "AV delay" (0–30 ms) for ventricular resynchronization in congestive heart failure patients with permanent atrial fibrillation. Their advantages include programming flexibility, avoidance of a cumbersome Y adapter (required for conventional VVIR devices), protection against far-field sensing of atrial activity (an inherent risk of dual cathodal devices with simultaneous sensing from both ventricles), and cost considerations. When a conventional dual chamber pacemaker is used for biventricular pacing, the "atrial" channel is generally connected to the LV and the "ventricular" channel to the RV. This arrangement provides:

1. LV stimulation before RV activation (LV preexcitation);
2. protection against ventricular asystole related to oversensing far-field atrial activity by dual cathodal devices in case of displacement of the LV lead towards the AV groove.

The DVI(R) mode behaves like the VVI(R) mode except that there are always two closely coupled stimuli (or electrocardiographically fused stimuli if the "AV delay" is very short) thereby facilitating evaluation of pacemaker function. Furthermore the DVI(R) mode provides absolute protection against far-field sensing of atrial activity in case of LV lead displacement. The short delay between LV and RV stimulation imposed by the shortest "AV delay" may not be a significant limitation in many patients because it is LV pacing that generally provides the salutary effect of biventricular pacing.

atrial fibrillation with 227
basic characteristics 309
choice/indications 147
lead/electrode positions 176
interactions of active and inactive electrodes lying side-by-side in 183
missing stimuli during, causes 187
pacemaker syndrome and 201, 313
with rate-adaptive function *see* VVIR pacemakers
sensitivity compared to AAI device 86
ventricular pacing rate with 200
ventricular lead
reversed connection of atrial and 165
VVI pacing positions 176
ventricular paced cycles at upper rate, number in termination of endless loop tachycardia 137
ventricular paced event (VP) 45, 293, 300
in automatic termination of endless loop tachycardia
monitoring of VP interval 139
"n" consecutive VP intervals shorter than given value 138
ventricular paced interval (VPI) 107, 108
ventricular paced rate (VPR) 107, 108, 109
with VVI and VVIR pacemaker 200
ventricular pacing/stimulation 19–33, 74–8
asynchronous (=VOO) 21, 292
atrial activity during 78
atrial sensing of, inappropriate 92
atrial stimulation without, DDD/DDDR pacing 318
in AV crosstalk testing 103
ECG 74–7
lack during provocation maneuvers for myopotential oversensing 317
left *see* left ventricular pacing
memory effect and 77
MI diagnosis difficulties during 311
and no atrial stimulation, DDD/DDDR pacing 318
QRS patterns 310–11
right *see* right ventricular pacing
spike within QRS complex identified as 155
ventricular ports
independent, biventricular pacing with 249, 253
interconnected, biventricular pacing with 249, 253
ventricular premature complexes (VPC; PVC)
atrial-based lower rate timing and responses after 151
unsensed by demand pacemaker 49
ventricular safety pacing with, manifestations of 102
ventricular pseudofusion beats 80, 297, 300
ventricular pseudopseudofusion beats 102
ventricular rates
histogram 279
rapid, myopotentials triggering 228
ventricular refractory period 20, 65, 66–7, 68
DDD pacemaker 90, 297
with four timing cycles at work 93
duration 66
functions 66
unblanked 68
ventricular resynchronization 247, 324, 326
ventricular safety pacing (VSP) interval or period 98–101, 300, 301
with atrial lead dislodged into RV 162
ECG patterns 101
with f waves unsensed 226
myopotential sensing and 229
pacemakers with 98–101, 301
pacemakers without 301
programming 304
with ventricular premature complexes, manifestations of 102
ventricular sense (VS; ventricular sensed events) 45, 293, 300
ventricular sense in refractory period (VR) 45

ventricular sensing
  oversensing 97, 316
    with postatrial ventricular blanking period too short 97
    preventing P wave detection 121
  undersensing, with postatrial ventricular blanking period too long 97
ventricular stimulation *see* ventricular pacing
ventricular tachycardia, unsustained, stored ECG 286
ventricular triggered pacing (VVT) 87
  explanation of 3 letter code 46
ventriculoatrial conduction, retrograde 258, 305, 306
  evaluation 132
    situations permitting 306
  impact on cardiac pacing 258
  lack of atrial capture suggested by 158
  in ventricular pacing 78
ventriculoatrial crosstalk (reverse crosstalk) 301, 321
  stored ECG 285
  testing for 321–2
ventriculoatrial synchrony 127–39, 305
  repetitive nonreentrant (RNRVAS) 134–5, 160, 306
    predisposing factors 134, 203
    prevention 135
    treatment 135
  retrograde 127–39
  sustained pacemaker-mediated rhythms related to 136
voltage 23, 293–4
  common units for pacemakers 14
  in Ohm's law 11, 13
  oversensing of intracorporeal voltages 316
  programming 26
  safety margin 30, 294–5
voltage threshold in analysis of lead problems 190
voltage transients *see* false signals
VOO pacemakers 21, 292
VVI pacemakers *see* ventricular inhibited pacemakers
VVIR pacemakers 309, 328
  basic characteristics 309
  biventricular pacing 328
  choice/indications 147
  minute ventilation sensors 208
  pacemaker syndrome 313
  ventricular pacing rate with 200
VVT mode *see* ventricular triggered pacing

walking test in follow-up 262
water equivalent of electricity 12
Wenckebach second degree block and AAI pacing follow-up 266
Wenckebach upper rate response and Wenckebach behavior 110, 111, 112–14, 118, 302
  atrial premature complexes and 117, 118
  preempted 254, 325
    and atrial undersensing in dual chamber pacing 315
  in rate-adaptive pacing 221
workload, rate-adaptive pacing and 212, 214

Foreword

There has been a near exponential increase in the amount of information available on the pathophysiology and management of heart diseases over the past decades. Meanwhile, our understanding of the underlying pathology and physiology has deepened and broadened with new methodologies to monitor cardiac structure and function. These developments have led to an overwhelming amount of information available to students, trainees, and physicians on all aspects of cardiac disease. What is in short supply is a comprehensive yet concise and clear description of the important cardiac conditions and disorders, an approach to their management, and an easily consulted and well indexed summary to be used at the bedside or in the clinic.

The Cardiology Handbook fills an extremely important, not well occupied niche in providing junior and senior practitioners alike with a brief yet detailed summary of "what you need to know" about virtually all important cardiovascular conditions.

This handbook does not aim to be a comprehensive review of all of the evidence pertaining to pathophysiology, investigation, and treatment of cardiovascular disorders. It does however wonderfully clearly get "straight to the point" and I think will be a frequently used and extremely effective resource for a brief "look up" in the clinic, in the emergency room, and on the wards.

I anticipate this handbook will be a treasured resource for senior medical students, trainees in internal medicine, emergency medicine, anesthesia, and other specialties where cardiovascular disorders are commonly seen. The effective use of figures and tables makes this appealing both visually and cognitively, and for those unfamiliar with the complex and varied terrain of cardiovascular medicine, will prove an outstanding trail map to allow successful navigation of unfamiliar terrain. In an era where there is often "too much information", this handbook provides just the right amount.

Sincerely,

Paul Dorian, MD, FRCPC, FHRS
Dexter H.C. Man Chair in Cardiology
Director Division of Cardiology, University of Toronto
Past President, Canadian Heart Rhythm Society

Table of contents

01 CARDIAC DIAGNOSTIC ASSESSMENT

1.1/ Cardiac physical examination 2
1.2/ Electrocardiogram (ECG) 8
1.3/ Stress test 22
1.4/ Transthoracic echocardiography (TTE) .. 27
1.5/ Transesophageal echocardiography (TEE) 39
1.6/ Stress echocardiography 43
1.7/ Chest x-ray (CXR) 45
1.8/ Coronary angiography 48
1.9/ Hemodynamic assessment 53
1.10/ Cardiac nuclear medicine 60
1.11/ Cardiac magnetic resonance imaging (cardiac MRI) 63
1.12/ Cardiac CT scan 65
1.13/ Cardiopulmonary exercise testing 66
1.14/ Exposure to radiation during cardiac examinations 67

02 CORONARY ARTERY DISEASE (CAD) & MYOCARDIAL INFARCTION

2.1/ Stable angina 72
2.2/ Biomarkers 80
2.3/ Myocardial infarction: Definition 81
2.4/ Unstable angina & NSTEMI 83
2.5/ STEMI 88
2.6/ Acute coronary syndrome: Adjuvant treatments 95
2.7/ Complications of myocardial infarction 98
2.8/ Revascularization – PCI 103
2.9/ Revascularization – Coronary artery bypass graft 106
2.10/ Prinzmetal angina (vasospastic angina) 108
2.11/ Cardiac syndrome X 108

03 HEART FAILURE

3.1/ Heart failure: assessment 112
3.2/ Systolic heart failure: management ... 115
3.3/ Diastolic heart failure (preserved LVEF) 123
3.4/ Decompensated heart failure 125
3.5/ Heart transplantation 130
3.6/ Long-term ventricular assist device 133
3.7/ Right heart failure 136
3.8/ Palliative care 136

04 VALVULAR HEART DISEASE

4.1/ Aortic stenosis 140
4.2/ Chronic aortic regurgitation 145
4.3/ Acute aortic regurgitation 148
4.4/ Mitral stenosis 148
4.5/ Chronic mitral regurgitation 151
4.6/ Acute mitral regurgitation 155
4.7/ Tricuspid stenosis 156
4.8/ Tricuspid regurgitation 156
4.9/ Pulmonary stenosis 157
4.10/ Pulmonary regurgitation 157
4.11/ Multivalvular heart disease 158
4.12/ Valvular prostheses 158
4.13/ Infective endocarditis 160
4.14/ Cardiovascular implantable electronic device infection 167
4.15/ Rheumatic fever 168

05 DISEASES OF THE PERICARDIUM & MYOCARDIUM

5.1/ Diseases of the pericardium: etiologies 172
5.2/ Acute pericarditis 173
5.3/ Incessant and recurrent pericarditis .. 174
5.4/ Cardiac tamponade 174
5.5/ Constrictive pericarditis 177
5.6/ Congenital anomalies of the pericardium 179
5.7/ Cardiomyopathies - Classification 179
5.8/ Hypertrophic cardiomyopathy 181
5.9/ Dilated cardiomyopathy 184
5.10/ Restrictive cardiomyopathy 184
5.11/ Cardiac amyloidosis 187
5.12/ Arrhythmogenic right ventricular dysplasia (ARVD) 188
5.13/ Isolated left ventricular noncompaction 190
5.14/ Takotsubo (stress) cardiomyopathy ... 191
5.15/ Myocarditis 191
5.16/ Indications for endomyocardial biopsy 193
5.17/ Cardiac tumors 194
5.18/ Cardiac complications of cancer 196

Table of contents

06 ARRHYTHMIAS

6.1/ Physiology 200
6.2/ Bradyarrhythmias 201
6.3/ Supraventricular tachyarrhythmias ... 204
6.4/ Atrial fibrillation 210
6.5/ Ventricular tachyarrhythmias 219
6.6/ Channelopathies 224
6.7/ Syncope 227
6.8/ Antiarrhythmic drugs (AAD) 229
6.9/ Amiodarone 232
6.10/ Permanent pacemaker (PPM) 233
6.11/ Cardiac resynchronization therapy (CRT) 239
6.12/ Implantable cardioverter-defibrillator (ICD) 241

07 ADULT CONGENITAL HEART DISEASE & HEART DISEASE IN PREGNANT WOMEN

7.1/ Segmental assessment & fetal circulation 248
7.2/ Atrial septal defect (ASD) 248
7.3/ Patent foramen ovale (PFO) 250
7.4/ Ventricular septal defect (VSD) 250
7.5/ Atrioventricular canal defect 251
7.6/ Patent ductus arteriosus 252
7.7/ Left ventricular outflow tract obstruction 253
7.8/ Coarctation of the aorta (CoA) 254
7.9/ Right ventricular outflow tract obstruction 256
7.10/ Tetralogy of Fallot (TOF) 257
7.11/ Transposition of the great arteries (D-TGV) 259
7.12/ Congenitally corrected Transposition of the great arteries (L-TGV) 261
7.13/ Ebstein's anomaly 262
7.14/ Marfan syndrome 263
7.15/ Fontan procedure 265
7.16/ Eisenmenger syndrome 266
7.17/ Cyanotic heart disease 267
7.18/ Anomalous pulmonary venous connection 268
7.19/ Congenital coronary artery anomalies 268
7.20/ Vascular annulus 269
7.21/ Cor triatriatum 270
7.22/ Heart disease in pregnant women 270

08 PERIPHERAL VASCULAR DISEASE

8.1/ Aneurysm of the thoracic aorta 276
8.2/ Acute aortic syndrome 279
8.3/ Abdominal aortic aneurysm (AAA) 282
8.4/ Other aortic diseases 283
8.5/ Peripheral artery disease (PAD) 285
8.6/ Atherosclerotic renovascular disease 289
8.7/ Cerebrovascular disease 290
8.8/ Pulmonary embolism 295
8.9/ Heparin-induced thrombocytopenia (HIT) 300
8.10/ Pulmonary hypertension 301

09 MISCELLANEOUS

9.1/ Preoperative assessment (non cardiac surgery) 310
9.2/ Primary & secondary prevention of cardiovascular disease 314
9.3/ Smoking cessation 315
9.4/ Dyslipidemia 316
9.5/ Hypertension 323
9.6/ Diabetes 329
9.7/ Physical activity 333
9.8/ Weight & Diet 336
9.9/ Obstructive sleep apnea syndrome ... 338
9.10/ Driving & Air travel 339
9.11/ Cardiovascular complications of systemic diseases 341
9.12/ Cardiovascular complications of trauma 343
9.13/ Poisoning 344
9.14/ Swan-Ganz catheter placement 346
9.15/ Cardiopulmonary resuscitation 347

To my parents, Diane and Marcel,
for their constant support,
and to Anne-Sophie, for
her extraordinary patience.

Preface

Cardiology is a fascinating medical specialty. This vast discipline combines various fields of expertise, including research, prevention, clinical evaluation, diagnostic examinations, therapeutic management, invasive interventions and rehabilitation.

As a result of the spectacular progress over the last two decades, cardiology now comprises sophisticated and advanced diagnostic and therapeutic tools (validated by evidence-based medicine) allowing cardiologists to more effectively manage their patients, who have greatly benefited in terms of survival and/or quality of life.

In relation to such an effervescent and increasingly complex discipline, physicians who have the privilege to practice cardiology must have access to resources that enable them to acquire, update, refine and organize their knowledge.

The purpose of this book is to provide a concise overview of modern cardiology. More than 10,000 pages of references have been condensed and organized into less than 350 pages. This pocket book provides practising clinicians with specific and accurate information on a particular subject. It is also designed to allow students, interns and all other personnel working in the field of cardiology to acquire and organize their valuable knowledge.

The design of this cardiology handbook was a captivating but colossal task. The information presented in this book is derived from numerous valid and up-to-date sources and has been verified by various reviewers, experts in their respective fields. The various recommendations are also derived from American, European or Canadian learned society evidence-based guidelines.

I sincerely hope that this book will inspire or maintain your passion for cardiology and I wish you an enjoyable read.

David Laflamme, MD, FRCPC, Cardiologist
Hôpital Charles-LeMoyne, Longueuil, Canada

Scientific revision

- **Dr Andrew M. Freeman**, MD, FACP, FACC, Director, Clinical Cardiology and Operations, Assistant Professor of Medicine, National Jewish Health, Denver, CO
  Chapter 1 - Cardiac diagnostic assessment

- **Dr Tiziano M. Scarabelli**, MD, PhD, FACP, FAHA, Associate Professor of Internal Medicine and Pharmacology; Director, Center for Heart and Vessel Preclinical Studies, St John Hospital & Medical Center, Wayne State University, Detroit, MI
  Chapter 1 - Cardiac diagnostic assessment

- **Dr Edward Koifman**, Levied Heart Center, Chaim Sheba Medical Center, Tel Hashomer, Israel
  Chapter 2 - Coronary artery disease & Myocardial infarction

- **Dr Émilie Belley-Côté**, MD, FRCPC, Cardiologist - Intensivist, Research fellow, Population Health Research Institute, McMaster University, Hamilton, Ontario
  Chapter 3 - Heart failure

- **Dr Shikhar Agarwal**, MD, MPH, Section of Interventional Cardiology, Heart and Vascular Institute, Cleveland Clinic, Cleveland, OH
  Chapter 4 - Valvular heart disease

- **Dr Ankur Kalra**, MD, FACP, Interventional Cardiology Fellow, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA
  Chapter 5 - Diseases of the pericardium & myocardium

- **Dr Charles Dussault**, MD, FRCPC, Clinical Cardiac Electrophysiology fellow Harvard Medical School, Boston, MA
  Chapter 6 - Arrhythmias

- **Dr Tabitha G. Moe**, MD, Adult Congenital Cardiology, Arizona Pediatric Cardiology, Phoenix Children's Heart Center, Phoenix, AZ
  Chapter 7 - Adult congenital heart disease & Heart disease in pregnant women

- **Dr Ryan Maybrook**, MD, Cardiology fellow, Division of Cardiovascular Diseases, University of Kansas Medical Center, Kansas City, KS
  Chapter 8 - Peripheral vascular disease

- **Dr Jaya Mallidi**, MD, MHS, Cardiology Fellow, Division of Cardiology, Baystate Medical Center, Tufts University, Springfield, MA
  Chapter 9 - Miscellaneous

Legal statement

Every physician is responsible for his or her acts. Although the recommendations and management presented in this book are based on valid, reliable and up-to-date references at the time of writing, the author and publisher decline all responsibility and remind the reader that every physician must practice medicine according to current medical and scientific guidelines, taking into account his or her own capacities and limitations, and, if necessary, seeking advice from more experienced specialists.

Cardiac diagnostic assessment

01

1.1/ Cardiac physical examination 2
1.2/ Electrocardiogram (ECG) 8
1.3/ Stress test 22
1.4/ Transthoracic echocardiography (TTE) 27
1.5/ Transesophageal echocardiography (TEE) 39
1.6/ Stress echocardiography 43
1.7/ Chest x-ray (CXR) 45
1.8/ Coronary angiography 48
1.9/ Hemodynamic assessment 53
1.10/ Cardiac nuclear medicine 60
1.11/ Cardiac magnetic resonance imaging (cardiac MRI) 63
1.12/ Cardiac CT scan 65
1.13/ Cardiopulmonary test 66
1.14/ Exposure to radiation during cardiac examinations 67

1.1/ CARDIAC PHYSICAL EXAMINATION

EXAMINATION OF THE PATIENT

GENERAL INSPECTION: Diaphoresis; Signs of hypoperfusion; Cachexia; Mitral facies; Cheyne-Stokes breathing

CUTANEOUS INSPECTION: Cyanosis (central vs peripheral); Pallor; Telangiectasias (Osler-Weber-Rendu; scleroderma); Tanned skin (hemochromatosis); Jaundice (liver disease); Ecchymoses (coagulopathy); Petechiae (thrombocytopenia); Purpura (vasculitis; endocarditis); characteristic axillary skin fold (pseudoxanthoma elasticum); Lentiginosis (LEOPARD; Carney); Lupus pernio - erythema nodosum (sarcoidosis); blue sclera (osteogenesis imperfecta); nicotine stains (smoking)

- **Familial hypercholesterolemia:** Arcus senilis; pathognomonic tendinous xanthomas (extensor tendons; MCP; Achilles tendon); Xanthelasma
- **Familial hypertriglyceridemia (LPL deficiency)**: Eruptive xanthomas; Lipemia retinalis
- **Dysbetalipoproteinemia:** Tuberous xanthomas (elbows; knees); Palmar xanthomas

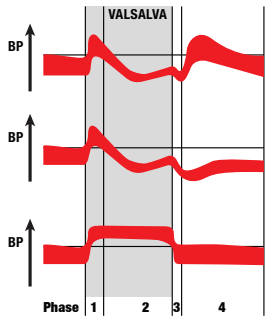
SIGNS OF ENDOCARDITIS: Roth's spots; Janeway lesions; Osler's nodes; splinter hemorrhages; mucosal petechiae

FUNDOSCOPY: hypertensive retinopathy (arteriovenous nicking; exudates; hemorrhages; cotton-wool spots; papilledema); diabetic retinopathy; endocarditis (Roth's spot); Hollenhorst plaque (cholesterol embolism); Lipemia retinalis

VITAL SIGNS

BLOOD PRESSURE: in both arms (± legs)

- **Large pulse pressure (> 50% of SBP)**: Age - HTN; AR; Patent ductus arteriosus; Ruptured aneurysm of the sinus of Valsalva; Fever; Anemia; Hyperthyroidism; Pregnancy; AV fistula; Paget's disease
- **Narrow pulse pressure (< 25% of SBP)**: Cardiac tamponade; Heart failure; Cardiogenic shock; Aortic stenosis
- **BP difference between the two arms > 10 mmHg**: Normal variant; PAD; Inflammatory vascular disease (Takayasu; giant cell arteritis); Supravalvular aortic stenosis; CoA; Aortic dissection
- **BP difference between the arms and legs > 20 mmHg**: Hill's sign (significant AR); CoA; severe PAD
- **Pulsus paradoxus:** ↘ SBP > 10 mmHg on inspiration
- **Orthostatic hypotension**: ↘ SBP > 20 mmHg or ↘ DBP > 10 mmHg during the first 3 minutes after standing up
- **Valsalva response**



NORMAL RESPONSE (SINUSOIDAL)
1. ↑ BP (↑ intrathoracic pressure)
2. ↓ venous return; ↓ BP; ↑ SVR; Reflex tachycardia
3. Release: ↓ BP (brief)
4. Overshoot: ↑ venous return; ↑ BP; ↓ SVR; Reflex bradycardia

NO OVERSHOOT (PHASE 4)
Systolic dysfunction

SQUARE WAVE
↑ filling pressure (little impact of ↓ venous return)

OTHER VITAL SIGNS: Pulse; heart rate regularity; Respiratory rate; Oxygen saturation; Temperature; Weight; Height; Waist

› **Body surface area (m^2)** = **0.007184 x weight (kg) x height (cm)** +

NECK

CAROTID PULSE

› **Shape**: ▸▸| Hemodynamic assessment (arterial recording)

› **Carotid sinus massage:** abnormal response if **asystole > 3 seconds (sinus arrest or AV block) and/or significant and symptomatic fall in SBP** +

JUGULAR VEINS

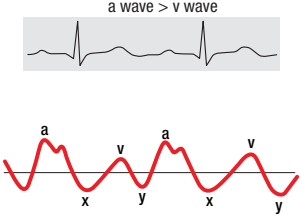
› **Jugular vein vs carotid artery**: Biphasic; Height modified by inspiration and position and hepatojugular reflux (HJR); Impalpable; Compressible +

› **Height**: distance between the sternal angle and the summit of venous pulsation; **normal < 3 cmH_2O** +

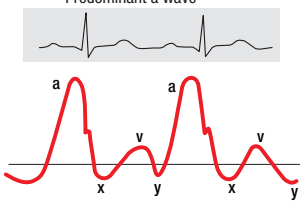
- **CVP (cmH_2O):** height above the sternal angle + 5 cmH_2O
- **Normal CVP**: **< 8 cmH_2O (< 6 mmHg)** +
- **Conversion**: **1.36 cmH_2O = 1 mmHg** +

› **Waves**: ▸▸| Hemodynamic assessment (atrial recording)

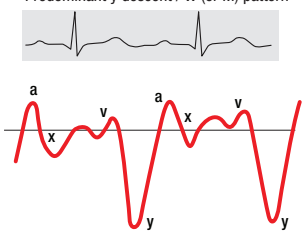
Normal pattern
a wave > v wave



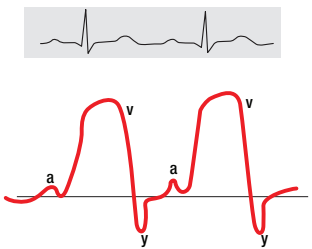
Tricuspid stenosis (or RVH)
Predominant a wave



Constrictive pericarditis
Predominant y descent / W (or M) pattern



Tricuspid regurgitation
Predominant v wave



› **Kussmaul's sign**: inspiratory increase (or absence of decrease) of CVP (constriction; RCM; RV infarction; pulmonary embolism; TS; RA tumor; right heart failure)

› **Hepatojugular reflux (HJR)**: Right upper quadrant (RUQ) compression (25 mmHg) x 15 seconds

- **Abnormal response**: **sustained ↗ of CVP > 3 cm throughout compression** (patient breathing normally)**; reflects right heart failure and/or wedge pressure > 15 mmHg** +

PRECORDIUM

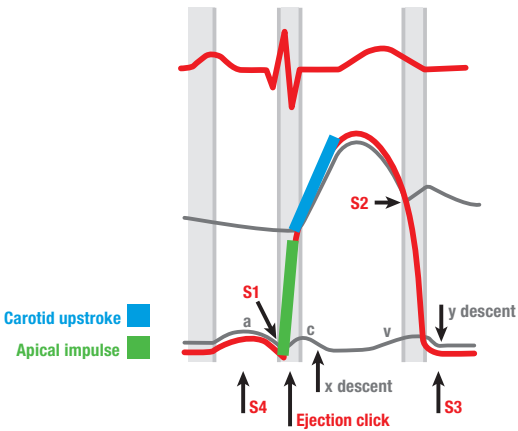
INSPECTION OF THE RIB CAGE: pectus excavatum; pectus carinatum; kyphoscoliosis; barrel chest; surgical scars; breathing; PPM / ICD

INSPECTION OF THE PRECORDIUM: position and dimensions of the apical impulse

PALPATION: patient in 30° supine position

- **Apical impulse**: with the fingertips; left lateral supine position as required; **medial to the midclavicular line; 4th or 5th intercostal space; diameter < 2 cm** +
  - **Apical pulsation: corresponds to isovolumic contraction of the LV**
  - **Hyperdynamic apex:** increased amplitude of apical impulse but of normal duration; AR; patent ductus arteriosus; MR; VSD; hyperthyroidism; anemia; pregnancy
  - **Sustained apical impulse**: **the impulse persists during or after the carotid upstroke; associated with pressure overload** (AS; HCM; HTN) +
  - **Enlarged apical impulse**: dilatation > 2 cm and/or shift downwards and to the left; associated with **LV volume overload** +
  - **Palpable S3**: LV volume overload
  - **Palpable S4**: noncompliant LV / ↗ end-diastolic pressure
  - **Triple apical impulse**: HCM (early-systole; end-systole due to dynamic LVOT obstruction; S4)
- **Ectopic pulsation**: LV aneurysm (mid-precordial or anterior axillary)
- **Left parasternal heave**: associated with RVH
- **Thrill:** palpate the 4 areas (palm of the hand at the level of the MCP joints)
- **Pulsation in the 2nd right intercostal space:** ascending aortic aneurysm
- **Pulsation in the 2nd left intercostal space**: PA dilatation

AUSCULTATION - SYSTOLIC HEART SOUNDS



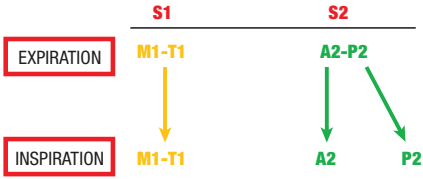
LOOK FOR: S1; Ejection click; Mid-systolic click; S2

S1: M_1-T_1 (interval: 20-30 ms); maximum at the apex; T1 mainly in the 5th left intercostal space; **precedes the carotid upstroke**

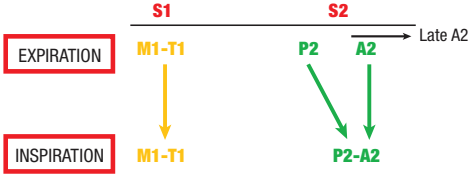
- **↗ Intensity of S1 (S1 ≥ S2 in the 2nd left intercostal space)**: Rheumatic MS (early stage); Hyperdynamic state (↗ dP/dt); PR < 120 ms; ↗ flow through mitral valve (VSD; patent ductus arteriosus)
- **↘ Intensity of S1**: Calcified MS (↘ mobility); Systolic dysfunction; PR > 200 ms; acute AR
- **Variable intensity of S1:** AF; AV dissociation; Tamponade
- **Split S1 (split sound in the 5th left intercostal space)**: RBBB; ASD (delayed T1); ST (delayed T1); Ebstein's anomaly

S2: A2-P2; maximum in the 2nd left intercostal space

- **Normal physiological splitting:** on inspiration; 2nd left intercostal space; interval: 20-60 ms



- **Normal but narrow inspiratory splitting**: PHT (associated with ↗ P2)
- **Increased splitting**: RBBB; severe MR (early A2); VSD (early A2); RVOT obstruction (late P2)
- **Fixed splitting (A2-P2 variation < 20 msec):** ASD; right heart failure (absence of variation of ejection volume according to RV preload)
- **Paradoxical splitting:** LBBB; RV PPM; AS; HCM; LV systolic dysfunction; AR (prolonged ejection)



- **↗ intensity of A2:** HTN; CoA; Ascending aortic aneurysm; Transposition of the great arteries; supravalvular AS
- **↘ intensity of A2:** Valvular AS; AR
- **↗ intensity of P2**: **P2 > A2 in the 2nd left intercostal space or P2 heard at the apex or palpable P2**; PHT; Supravalvular RVOT obstruction
- **↘ intensity of P2**: Valvular PS; pulmonary regurgitation (except if secondary to PHT); Transposition of the great arteries
- **Single S2**: ↘ A2 (AS) or ↘ P2 (PS); Transposition of the great arteries

VALVULAR EJECTION CLICK: coincides with carotid upstroke (120-140 ms after QRS); high-pitched sound; diffuse radiation; best heard in lower left parasternal region; associated with bicuspid aortic valve (valve still pliable) or **congenital PS** **(↘ click on inspiration; valve still pliable)**

- **Vascular ejection click**: **Aortic root dilatation**; PA dilatation (idiopathic; post-stenotic; PHT)

MID-SYSTOLIC CLICK OF MVP: non-ejection click (after the carotid pulsation); high-pitched sound; earlier if the patient stands up; ± MR murmur

AUSCULTATION - DIASTOLIC HEART SOUNDS

LOOK FOR: S2; Opening snap; Pericardial knock; S3; Tumor plop; S4; Friction rub

MITRAL OPENING SNAP: High-pitched sound; stethoscope diaphragm at the apex; **A2-opening snap interval inversely proportional to the severity of MS** (40-120 ms after S2); interval decreases with tachycardia; ↘ intensity of opening snap when the valve is calcified

PERICARDIAL KNOCK: Constrictive pericarditis; early diastolic sound (at the end of the y descent); 100-120 ms after S2

S3: left lateral supine position; stethoscope bell at the apex; 140-160 ms after S2; during rapid ventricular filling (at the end of the y descent); associated with **ventricular volume overload** +

- **Etiologies:** Dilated cardiomyopathy; heart failure; MR; AR; VSD; patent ductus arteriosus; diastolic dysfunction; young subjects in good health; normal pregnancy
- **Right S3:** lower left parasternal region; ↗ on inspiration; TR; right heart failure; PHT

S4: left lateral supine position; stethoscope bell at the apex; occurs during atrial kick (after the P wave); associated with a **poorly compliant ventricle** and **↗ filling pressure** +

- **Etiologies**: HTN; AS; HCM; LVH; Ischemia; Acute AR; Acute MR; Age
- **Right S4**: lower left parasternal region; ↗ on inspiration; RVOT obstruction; PHT

SUMMATION GALLOP: fusion of S3 and S4 during tachycardia

TUMOR PLOP: prolapse of the tumor through the AV valve; sound varies with position

PERICARDIAL FRICTION RUB: **1 or 2 or 3 components** (rapid ventricular filling; atrial kick; ventricular systole); forced expiration while leaning forward; stethoscope diaphragm in left parasternal region

AUSCULTATION - MURMURS

IDENTIFY: Moment of the cycle; Configuration (crescendo; decrescendo; crescendo-decrescendo; plateau); Site; Radiation; Tone; Intensity; Modifiers (breathing; special maneuvers)

- **1/6**: Very faint murmur (barely perceptible)
- **2/6**: Faint murmur but heard immediately
- **3/6:** Moderate murmur
- **4/6**: Palpable thrill
- **5/6:** Very loud; heard even when only part of the stethoscope is in contact with the chest
- **6/6**: Heard even when the stethoscope is not in contact with the chest

BENIGN MURMUR: 1-2/6 in left parasternal region; Ejection murmur; S2 of normal intensity with normal physiological splitting; No other heart sounds or murmurs; No LVH (on examination or ECG); Murmur not increased by Valsalva maneuver or standing

INDICATIONS FOR TTE: Diastolic or continuous or holosystolic or end-systolic or early systolic murmur or associated with ejection click or ≥ 3/6 with mid-systolic peak or radiating to the neck or back or signs or suspicion of MR, MVP, HCM or VSD on dynamic auscultation

SYSTOLIC MURMUR	
Mid-systolic (often diamond-shaped)	• Benign • Ejection murmur: High output state (pregnancy; hyperthyroidism; anemia; AV fistula; AR; PR; ASD) • Aortic stenosis (supravalvular; valvular; subvalvular) • Aortic sclerosis • HCM • PS (supravalvular; valvular; subvalvular) • CoA • Functional / ischemic MR

Holosystolic 	• MR • TR • VSD (restrictive)
Early systolic 	• Acute MR • Primary TR (without PHT) • VSD: small muscular VSD or large VSD with significant PHT
End-systolic 	• MVP • Functional / ischemic MR (↗ on exercise) • Tricuspid valve prolapse
DIASTOLIC MURMUR (ALWAYS INVESTIGATE)	
Early diastolic 	• AR • Graham-Steell: PR secondary to PHT (decrescendo; high-pitched; signs of associated PHT) • PR without PHT (faint murmur)
Mid-diastolic 	• MS • TS • Austin-Flint (absence of opening snap) • Myxoma • ↗ diastolic flow through AV valve (MR; TR; VSD; patent ductus arteriosus; ASD; abnormal pulmonary venous return) • Carey Coombs murmur (mitral valvulitis during acute rheumatic fever)
End-diastolic 	• MS (presystolic accentuation) • TS • Austin-Flint • Myxoma • Rytand's murmur: diastolic mitral regurgitation in a context of complete AV block
CONTINUOUS MURMUR (OFTEN PATHOLOGICAL)	
Starts at systole and continues uninterrupted during diastole  	• Patent ductus arteriosus (Gibson's murmur; machinery murmur) • Aortopulmonary window • Coronary arteriovenous fistula • Ruptured aneurysm of the sinus of Valsalva • Neck venous hum • Mammary murmur of pregnancy • Stenosis of peripheral branch of pulmonary artery • Lutembacher's syndrome: MS + ASD • CoA / Intercostal collateral vessels • Pulmonary or systemic AV fistula • Bronchial collateral vessels

DYNAMIC AUSCULTATION

MANEUVERS	AS	HCM	MVP	MR	OTHER
Valsalva (↘ preload)	↘	↗	↗ duration of murmur	↘	↘ AR
Standing up (↘ preload)	↘	↗	↗ duration of murmur	↘	
Squatting or leg raising (↗ preload)	unchanged or ↗	↘	↘ duration of murmur	↗	↗ AR - ↗ VSD
Hand grip (↗ afterload)	unchanged or ↘	↘	↘ duration of murmur	↗	↗ AR - ↗ VSD ↗ MS (↗ HR)
Amyl nitrate (↘ afterload)	↗	↗	↗ duration of murmur	↘	↗ MS (↗ HR) ↘ AR - ↘ VSD ↘ Austin Flint
Post-PVC (↗ contractility)	↗	↗	↘ duration of murmur (↗ LV volume)	un-changed	

INSPIRATION: louder right heart sounds/murmurs (except for pulmonary valve ejection click); ↗ splitting of S2

PHYSICAL EXAMINATION - OTHER EXAMINATIONS

LUNGS: crackles; effusion; wheezing; pleural friction rub

ABDOMEN: Liver (pulsation); Ascites; Splenomegaly; Aorta; Murmurs

LOOK FOR PRESACRAL EDEMA

UPPER LIMBS: clubbing; arachnodactyly; signs of endocarditis; nicotine stains; sclerodactyly; pulse in both arms

LOWER LIMBS: murmurs; lower limb edema; pulse in both legs; capillary refill; discoloration; ulcer; coldness; atrophic changes; hair loss

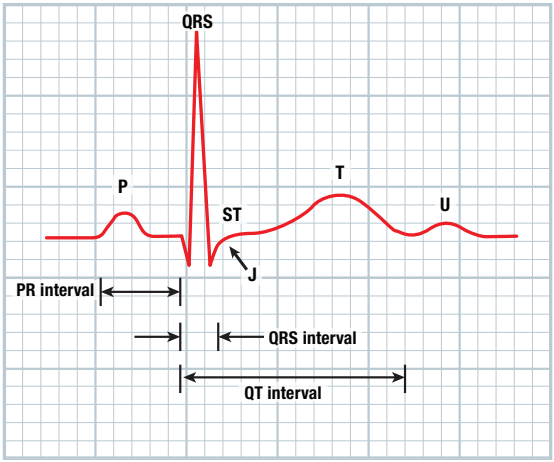
- **Radiofemoral delay:** CoA
- **Pulse**: 0 = absent; 1 = decreased; 2 = normal; 3 = bounding

BRIEF NEUROLOGICAL EXAMINATION

1.2/ ELECTROCARDIOGRAM (ECG)

SYSTEMATIC APPROACH

a) **HEART RATE**: 1500 / number of small squares between 2 QRS or 300-150-100-75-60-50-43-38
b) **RHYTHM** (⏭ Chapter 6 - Arrhythmias)
c) **P WAVE:** morphology
d) **AV CONDUCTION**
e) **QRS**: frontal axis; intraventricular conduction; precordial QRS transition; voltage / chamber hypertrophy
f) **REPOLARIZATION**: ST segment - T wave - QT interval - U wave
g) **MYOCARDIAL INFARCTION / Q WAVE**



NORMAL VALUES	
Calibration	• **Vertical: 10 mm = 1 mV** • **Horizontal: 1 mm = 40 msec**
P wave duration and amplitude	< 120 ms and < 2.5 mm in amplitude
P wave axis	60° (positive I-II-aVL-aVF; negative aVR) Normal axis: 0-90°
PR interval	120-200 ms
QRS duration	≤ 110 ms
QRS axis	-30° to +90°
Precordial QRS transition	R = S in V3 or V4
QRS amplitude	• **Limbs:** > 5 mm • **Precordial**: > 10 mm
J Point / ST segment	**Elevation** • **V2-V3**: < 2 mm (men > 40 years); < 2.5 mm (men < 40 years); < 1.5 mm (women) • **Other leads**: < 1 mm **Depression**: < 0.5 mm
T wave	• **Positive:** I-II-V3-V4-V5-V6 › **V5-V6**: T wave inversion < 1 mm in 2% • **Negative:** aVR • **Variable:** aVL-III-V1-V2 • **Maximum amplitude V2**: < 14 mm (men) and 10 mm (women)
QTc	• **Men:** < 450 ms • **Women:** < 460 ms

TECHNICAL CONSIDERATIONS

ARM LEAD REVERSAL: P and QRS and T wave inverted in I and aVL but not in V6

PRECORDIAL LEAD MALPOSITION: abnormal precordial QRS transition

RIGHT HEART OR POSTERIOR LEADS: V3R-V4R or V7-V8-V9

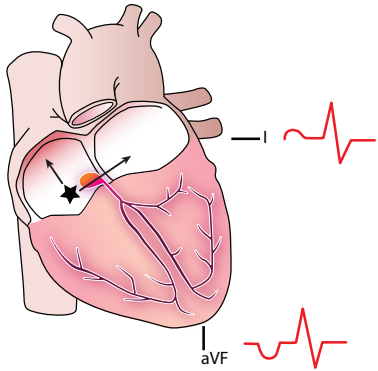
ARTIFACTS: tremor; Parkinson's disease (pseudo-flutter)

SINUS RHYTHM

▸▸| Chapter 6 - Arrhythmias

SINUS RHYTHM (SR): origin of sinoatrial node; HR 60 -100 bpm

- **Sinus tachycardia**: HR > 100 bpm
- **Sinus bradycardia**: HR < 60 bpm
- **Normal atrial activation**: RA to AV node and to LA; P axis 0° to +90° (positive P wave I-II-aVL-aVF); biphasic P wave in V1-V2; duration < 120 ms
- **Retrograde atrial activation**: retrograde AV conduction or ectopic atrial pacemaker close to AV node; negative P wave in II and aVF



SINUS ARRHYTHMIA: phasic respiratory variation of the duration of the PP interval; variation ≥ 120 ms or PPmax - PPmin / PPmin > 10%

SUPRAVENTRICULAR ARRHYTHMIAS

▸▸| Chapter 6 - Arrhythmias

VENTRICULAR ARRHYTHMIAS

▸▸| Chapter 6 - Arrhythmias

P WAVE

	NORMAL	RA ABNORMALITY	LA ABNORMALITY
II			V1				• Axis 60° • Duration < 120 ms	• Axis > 75°	• Axis terminal portion -30° to -90° (negative in III)

INTRA-ATRIAL CONDUCTION BLOCK: Duration of P wave > 120 ms; biphasic P wave in inferior leads; does not satisfy the criteria for RA or LA anomaly

› **Abnormal activation:** RA activation → Bachmann's bundle block → LA activation from coronary sinus (from inferior to superior)

AV CONDUCTION

▸▸| Chapter 6 - Arrhythmias

NORMAL PR INTERVAL: 120-200 ms

LONG PR INTERVAL: PR > 200 ms; 1st degree AV block

SHORT PR INTERVAL: PR < 120 ms in sinus rhythm; rule out accessory pathway

› **Lown-Ganong-Levine syndrome**: atrio-His accessory pathway (James fibers) short-circuiting the AV node; narrow QRS

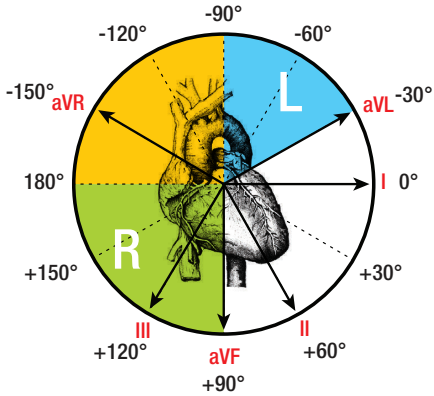
X:Y AV CONDUCTION: failure of AV node to conduct certain atrial impulses to the ventricle; **the refractory period of the AV node is longer when it is stimulated more rapidly (decremental conduction)**

› **AV block with variable conduction**: 2:1 3:1...; frequent in atrial flutter

AV DISSOCIATION: independent atrial and ventricular rhythms; 3 situations:

1) 3rd degree AV block; RR interval > PP interval
2) Accelerated junctional rhythm or junctional tachycardia or VT (without retrograde VA conduction); RR < PP; ± fusion or capture beats
3) Sinus bradycardia with junctional or ventricular escape (without retrograde VA conduction); RR < PP; ± isorhythmic dissociation

FRONTAL QRS AXIS

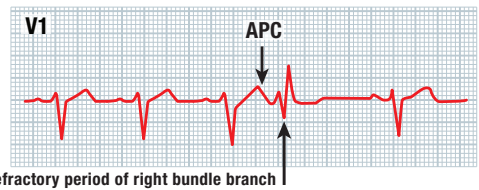


Normal axis	-30° to + 90°	I + aVF + (if aVF - → II +)	
Right axis deviation	+90° to +180°	I - aVF +	**DDx:** RVH; LPHB; dextrocardia; lateral infarction; secundum ASD; vertical heart (COPD); pulmonary embolism
Left axis deviation	-30° to -90°	I + aVF - and II -	**DDx**: LVH; LAHB; primum ASD; complete AV canal defect; Tricuspid atresia (under-developed RV); pregnancy; ascites; inferior infarction
Extreme "North-West" axis deviation	- 90° to 180°	I - aVF -	

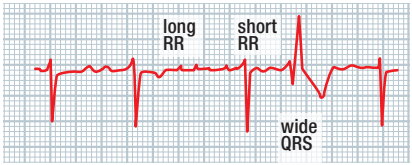
INDETERMINATE AXIS: Equiphasic QRS in all frontal leads (with no dominant QRS); axis perpendicular to the frontal plane

QRS: INTRAVENTRICULAR CONDUCTION

ABERRANT CONDUCTION OF SUPRAVENTRICULAR BEATS: arrival of a supraventricular beat during the relative refractory period of intraventricular conduction tissue; conduction with wide QRS (RBBB > LBBB morphology)



ASHMAN PHENOMENON: **Long RR then short RR** → wide QRS (frequent RBBB morphology); **long RR associated with ↗ refractory period of His-Purkinje tissue**

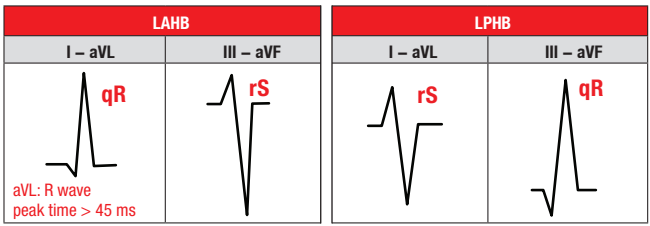


LAHB (LEFT ANTERIOR HEMIBLOCK)

1) Left axis deviation -45° to -90°
2) qR in I and aVL
3) rS in III and aVF
4) QRS duration < 120 ms
5) R wave peak time in aVL > 45 ms
   - Late precordial QRS transition
   - **Rule out differential diagnoses**: LVH; COPD; inferior infarction

LPHB (LEFT POSTERIOR HEMIBLOCK)

1) Right axis deviation +90° to +180°
2) rS in I and aVL
3) qR in III and aVF
4) QRS duration < 120 ms
   - **Rule out differential diagnoses**: RVH; COPD; lateral infarction; dextrocardia; arm lead reversal



LBBB (LEFT BUNDLE BRANCH BLOCK)

1) QRS ≥ 120 ms
2) Wide monophasic R wave in I-aVL-V5-V6
3) Absence of septal q wave in I-V5-V6
4) R wave peak time > 60 ms in V5-V6
5) ST and T in opposite direction to QRS (appropriate discordance)

Acute myocardial infarction with a LBBB (Sgarbossa criteria)	**1) ST elevation ≥ 1 mm in leads with positive QRS (inappropriate concordance)** **2)** ST depression ≥ 1 mm V1-V2-V3 (inappropriate concordance) **3)** ST elevation ≥ 5 mm in leads with negative QRS (extreme discordance)
Old myocardial infarction in LBBB	**1) Cabrera's sign:** Notch of the upslope of the S wave in V2-V3-V4 **2) Chapman's sign:** Notch of the upslope of the R wave in V5-V6-I-aVL

INCOMPLETE LEFT BUNDLE BRANCH BLOCK

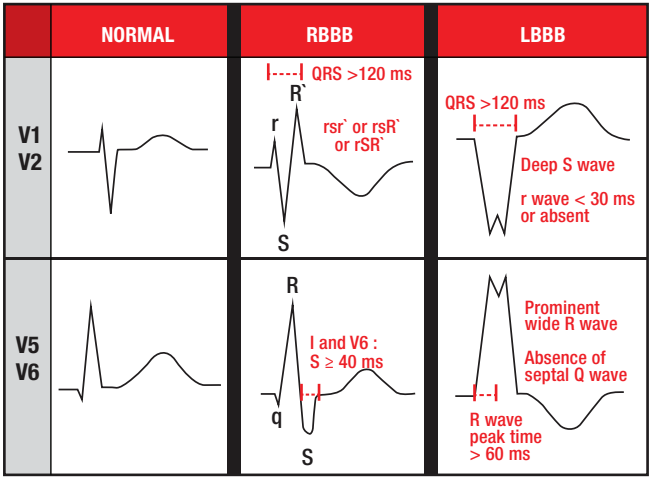
1) QRS 110-119 ms
2) LVH pattern
3) R wave peak time > 60 ms in V5-V6
4) Absence of septal q wave in I-V5-V6

RBBB (RIGHT BUNDLE BRANCH BLOCK)

1) QRS ≥ 120 ms
3) rsr', rsR', or rSR' in V1 or V2 (width of R' or r' > width of r)
4) S > 40 ms in I and V6 (S larger than R in V6)
   - In a minority of patients, wide monophasic R wave in V1 and/or V2 (with R wave peak time > 50 ms in V1)
   - **If axis deviation:** consider bifascicular block (RBBB with LAHB or RBBB with LPHB)
   - **If bifascicular block with ↗ PR**: consider lesion of 3 branches with prolonged HV interval

INCOMPLETE RIGHT BUNDLE BRANCH BLOCK

1) QRS 110-119 ms
2) Other criteria similar to RBBB

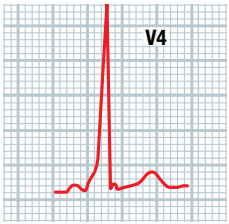


NONSPECIFIC INTRAVENTRICULAR CONDUCTION DISORDER

1) QRS > 110 ms
2) Absence of criteria of RBBB or LBBB

VENTRICULAR PRE-EXCITATION

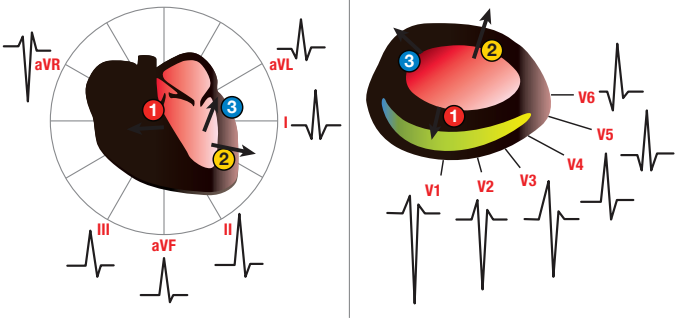
1) PR interval < 120 ms (in sinus rhythm)
2) **Delta Wave:** slow rise of the initial portion of the QRS
3) QRS ≥ 120 ms
4) Secondary ST and T anomalies
   - Possible pseudo-infarction (Q waves)
   - **Concertina effect**: the degree of pre-excitation can vary according to conduction and the refractory period of the accessory pathway and AV node



SITE OF ACCESSORY PATHWAY	V1	aVF	aVL
Left lateral	+	+	-
Posterior or left septal	+	-	+
Posterior or right septal	-	-	+
Anterior or right lateral	-	+	+

QRS: PRECORDIAL R WAVE TRANSITION

NORMAL VENTRICULAR ACTIVATION: **1)** Left-to-right septal activation (septal q wave in I-aVL-V5-V6; septal r wave in aVR and V1; **2)** Anterior LV then lateral LV activation; **3)** Posterobasal LV activation



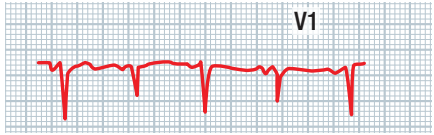
NORMAL PRECORDIAL TRANSITION: rS V1 → qR V6; R = S in V3 or V4

› **DDx of abnormal precordial transition**: lead malposition; dextrocardia; anterior or anteroseptal or posterior myocardial infarction; LVH; RVH; LAHB; LBBB; RBBB; dilated or infiltrative cardiomyopathy; pre-excitation (right or anteroseptal accessory pathway); COPD; pneumothorax; chest wall anomaly...

LOW VOLTAGES: QRS amplitude **< 5 mm on frontal leads and < 10 mm on precordial leads**

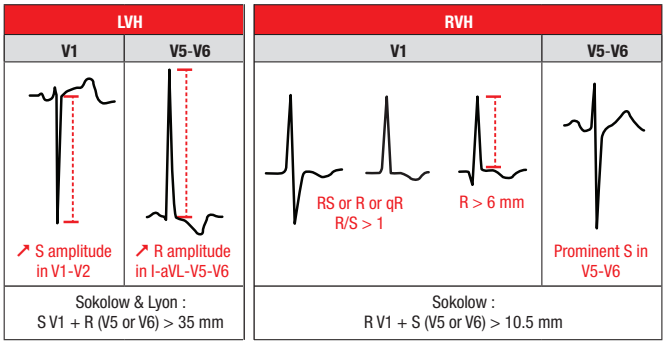
› **DDx**: COPD; obesity; cardiomyopathy; infiltrative disease - amyloidosis - tumor; myocarditis; extensive MI; pericardial effusion; constrictive pericarditis; pleural effusion; myxedema; anasarca; calibration; left pneumothorax

ELECTRICAL ALTERNANS: QRS amplitude varies between beats



- **DDx**: pericardial effusion; severe cardiomyopathy; severe AR; supraventricular tachycardia
- **P wave alternans**: pathognomonic of pericardial effusion
- **T wave alternans**: long QT syndrome

QRS: CHAMBER HYPERTROPHY



LEFT VENTRICULAR HYPERTROPHY (LVH): multiple criteria

- **Sokolow & Lyon:** S V1 + R (V5 or V6) ≥ 35 mm
- **Cornell voltage**: S V3 + R aVL ≥ 28 mm (men) and ≥ 20 mm (women)
- **R aVL**: > 11 mm (> 18 mm if left axis deviation)

ROMHILT-ESTES SCORE		
Frontal leads: R or S max ≥ 20 mm or SV1 or SV2 ≥ 30 mm or RV5 or RV6 ≥ 30 mm	3 points	≥ 5 points: definite LVH 4 points: probable LVH
ST-T abnormality (without Digoxin) **ST-T abnormality (with Digoxin)**	3 points 1 point	
LA abnormality	3 points	
Left axis deviation (-30° to -90°)	2 points	
QRS duration ≥ 90 ms	1 point	
R wave peak time V5 or V6 ≥ 50 ms	1 point	

- **Other**: secondary repolarization abnormalities; left axis deviation; LA abnormality; Prolonged R wave peak time in V5-V6

- **LVH associated with LBBB**: consider concomitant LVH if: **A)** LA abnormality; **B)** QRS > 155 ms; **C)** Precordial voltage criteria
- **LVH associated with RBBB**: consider concomitant LVH if: **A)** LA abnormality; **B)** Left axis deviation; **C)** S V1 > 2 mm; **D)** R V5 or V6 > 15 mm; **E)** Left axis deviation and precordial SR max > 29 mm; **F)** R in I > 1 mm

RIGHT VENTRICULAR HYPERTROPHY (RVH): multiple criteria

- **Sokolow**: R V1 + S (V5 or V6) > 10.5 mm
- **R/S V1**: > 1
  - **DDx of prominent R wave in V1-V2**: **Lead malposition; Dextrocardia; posterior myocardial infarction; Duchenne muscular dystrophy; RVH (right axis deviation); septal HCM; RBBB; Preexcitation (left posterior or lateral pathway); pediatric ECG** +
- **R V1:** > 6 mm
- **R wave peak time V1**: > 35 ms
- **R/S V5 or V6**: < 0.75 (V5) or < 0.4 (V6)
- **S V5 or V6**: > 10 mm (V5) or > 3 mm (V6)
- **Other:** Right axis deviation; T wave inversion V1-V2-V3; RA abnormality; S1S2S3; S1Q3
- **RVH associated with RBBB**: consider concomitant RVH if **R in V1 > 15 mm** and right axis deviation +

BIVENTRICULAR HYPERTROPHY: look for criteria of both RVH and LVH

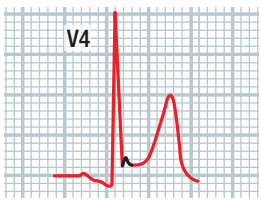
- **LVH:** consider concomitant RVH if → prominent S in V5 or V6; right axis deviation; unusual biphasic R/S complexes on several precordial leads (late precordial transition); RA hypertrophy
- **RVH**: consider concomitant LVH if → combined R/S amplitude in V2 to V4 > 60 mm; LA hypertrophy; prominent R wave in right and left precordial leads

REPOLARIZATION: ST - T - QT - U

ST ELEVATION (AT J POINT IN ≥ 2 CONTIGUOUS LEADS	
V2 – V3	• Men ≥ 40 years: ≥ 2 mm • Men < 40 years: ≥ 2.5 mm • Women: ≥ 1.5 mm
All other leads	≥ 1 mm
V3R – V4R – V7 – V8 – V9	≥ 0.5 mm

DDX OF ST ELEVATION: Myocardial ischemia / STEMI; normal variant (early repolarization); LV aneurysm; pericarditis; myocarditis; cardiomyopathy; Prinzmetal angina / Vasospasm; Takotsubo; LVH; LBBB; pre-excitation; PPM; Brugada syndrome; pulmonary embolism; hyperkalemia; intracranial haemorrhage / SAH; hypothermia (Osborn); post-ECV; lead malposition; hypercalcemia; Rx (class IC AAD)…

- **Early repolarization:** 2-5% of the population; concave ST segment elevation (V2-V3-V4-V5) from J point; notch at J point; prominent T wave



ST DEPRESSION (AT J POINT ON ≥ 2 CONTIGUOUS LEADS)
≥ 0.5 mm (horizontal or descending)

DDX OF ST DEPRESSION: ischemia; LVH; RVH; LBBB; RBBB; pre-excitation; myocarditis; pericarditis; cardiomyopathy; amyloidosis; hypokalemia; Digoxin; pulmonary embolism; intracranial hemorrhage; stroke; acute systemic disease; sepsis; fever; acidosis; anemia; postoperative period after cardiac surgery; hyperventilation...

T WAVE INVERSION (ON ≥ 2 CONTIGUOUS LEADS)
≥ 1 mm; leads with R/S > 1

DDX OF T WAVE INVERSION: persistent juvenile pattern; RBBB; LBBB; pre-excitation; LVH; RVH; apical HCM; ARVD; Brugada; acute CNS lesion; PVC; ventricular pacing ("*memory T wave*")

› **Persistent juvenile pattern:** T wave inversion in V1-V2-V3 persisting since childhood

GIANT T WAVE INVERSION (>10 MM): Apical HCM; ischemia; Wellens' syndrome; post-STEMI; CNS lesion

› **Wellens' syndrome**: deep T wave inversion in V2-V3-V4 with ↗ QT interval associated with proximal LAD lesion

SYMMETRICALLY PEAKED T WAVES
≥ 5 mm (frontal leads); ≥ 10 mm (precordial leads)

DDX OF SYMMETRICALLY PEAKED T WAVES: hyperkalemia; acute ischemia (early STEMI); CNS lesion; LVH or LBBB (asymmetrical T waves)

PROLONGED QT INTERVAL
QTc ≥ 450 ms (men) or ≥ 460 ms (women)

DDX OF PROLONGED QT INTERVAL: medication - **www.qtdrugs.org** (interrupt agent when **QTc > 500 ms or increases by > 60 ms**); long QT syndrome; hypocalcemia; hypokalemia; hypomagnesemia; hypothermia; CNS lesion; ischemia; severe bradycardia... +

› **Normal QT**: **< 1/2 RR interval**
- **Bazett's equation**: **QTc = QT (msec) / √R-R (s)** (HR < 100 bpm) +
- **Linear model**: **QTc = QT + 1.75 x (HR - 60)**
- **Significant change on medication: > 60 ms**

› **Measurement of QT:** longest interval (often V2-V3); draw a tangent from the most pronounced descent of the T wave to intersect the TP segment

› **QT associated with prolonged QRS**: **JTc interval** (QT duration - QRS duration) (normal < 370 ms)

SHORT QT INTERVAL: **QTc ≤ 390 msec** (HR < 100 bpm) +

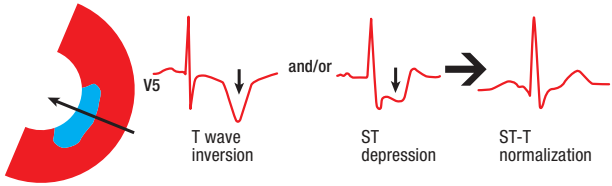
› **Etiologies**: hypercalcemia; hyperkalemia; Digoxin; congenital short QT syndrome

PROMINENT U WAVE (> 2 MM): hypokalemia; hypercalcemia; Digoxin; class IA and IC AAD; thyrotoxicosis; intracranial hemorrhage; congenital long QT syndrome

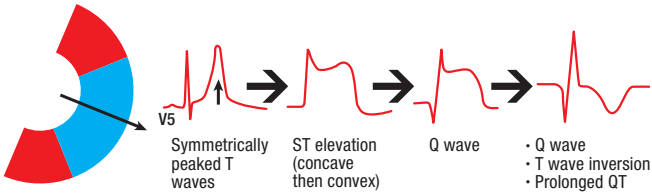
› **U wave inversion**: leads on which the T wave is positive; sign of ischemia

MYOCARDIAL INFARCTION (▶▶| Chapter 2 - Myocardial infarction)

SUBENDOCARDIAL ISCHEMIA



TRANSMURAL ISCHEMIA



ST ELEVATION OR SYMMETRICALLY PEAKED T WAVES	
V1-V2	Anteroseptal infarction
V3-V4	Anteroapical infarction
V5-V6 (± aVL - I)	Anterolateral infarction
V1-V2-V3-V4-V5-V6	Extensive anterior infarction
aVL-I	Lateral infarction
II-III-aVF	Inferior infarction
V3R-V4R (± V1) (+ II-III-aVF)	RV infarction
V7–V8–V9 (mirror changes in V1–V2)	Posterior infarction

ABNORMAL Q WAVE (IN ≥ 2 CONTIGUOUS LEADS)	
V2-V3	QS or Q duration ≥ 20 ms
I-II-aVL-aVF V4-V5-V6 V7-V8-V9	QS or Q ≥ 30 ms and > 1 mm
V1-V2	Consider old posterior infarction if R > 40 ms with R/S ≥ 1 in absence of conduction disorder

DDX OF Q WAVES (PSEUDO-INFARCTION): septal Q waves (V4-V5-V6; I; aVL; aVF); normal variant in V1 or III; LVH; RVH; LBBB; LAHB; pre-excitation; myocarditis; RCM - Infiltration (amyloidosis; sarcoidosis; tumor); HCM; DCM; dextrocardia; hyperkalemia; chest deformity; pneumothorax; COPD; pulmonary embolism...

CLINICAL ENTITIES

ACUTE PERICARDITIS: 4 phases

1) Diffuse ST elevation (concave); PR segment depression; mirror image in aVR
2) Normalisation of ST segment with depression of J point
3) T wave inversion
4) Normalisation of T waves

PERICARDIAL EFFUSION: low voltage; electrical alternans

PULMONARY EMBOLISM: sinus tachycardia; QR or qR in III-aVF / V1-V2-V3 (pseudo-infarction); S1Q3T3 (12% of patients); ST depression (sometimes elevation) and T wave inversion in V1-V2-V3; complete or incomplete RBBB; delayed precordial QRS transition; right axis deviation

HYPERTROPHIC CARDIOMYOPATHY (HCM): LVH; LAH; left axis deviation; pseudo-infarction (Q waves - inferior - lateral - precordial leads); giant T wave inversion in precordial leads (apical HCM)

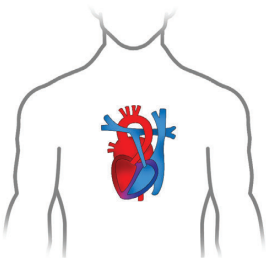
PRIMUM ASD: RBBB; left axis deviation; RAH

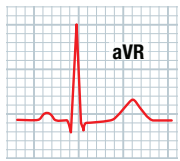
SECUNDUM ASD: Incomplete RBBB; right axis deviation; RAH; notch in the upslope of the R wave in inferior leads

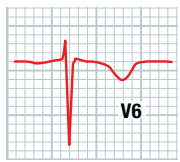
MITRAL STENOSIS: RVH; right axis deviation; LAH ± RAH

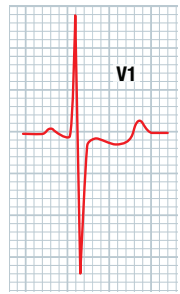
LEFT VENTRICULAR ANEURYSM: persistent convex ST elevation (3 weeks post-MI) in the presence of a Q wave

DEXTROCARDIA: inverted P and QRS and T waves in I and aVL; positive QRS in aVR; inverted precordial QRS transition





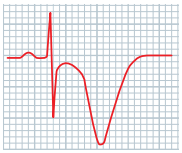




COPD: RVH; RAH; right axis deviation; ↘ QRS amplitude on frontal leads (electrical isolation due to hyperinflation); delayed precordial transition (cardiac position modified by hyperinflation and lowering of the diaphragm); persistent S wave in all precordial leads; low amplitude R wave in V6; pseudoinfarction (Q waves); MAT - APCs - AF - Flutter

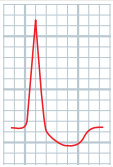
ACUTE CNS LESION: giant T wave inversions on precordial leads (sometimes positive and prominent); ↗ QT interval; U waves; transient ST elevation; ± Torsade de pointes

V2



DIGOXIN IMPREGNATION: **scooped ST**; flattened T wave; ↘ QT interval; ↗ PR interval; U wave

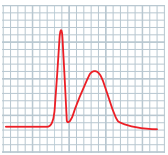
V5



DIGOXIN TOXICITY: sinus bradycardia; sinus arrest; ectopic atrial tachycardia; "regularized" AF (junctional escape rhythm); junctional tachycardia; AV block; PVCs; VT; bidirectional VT; VF

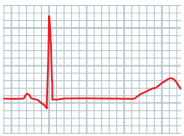
HYPERCALCEMIA: ↘ QT interval; sharp T wave upstroke; ↗ PR interval

V5



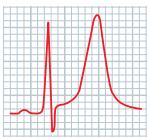
HYPOCALCEMIA: **↗ QT interval** (due to ↗ ST interval; T wave unchanged)

V5



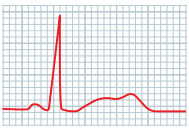
HYPERKALEMIA: **symmetrically peaked T waves**; ↘ QT interval → **↗ QRS duration** and ↗ PR interval; conduction disorders (RBBB; LBBB; bifascicular block; AV block) → **flattened P wave** (or even loss of P wave with sinoventricular rhythm; unexcitable atrial muscle); ST elevation → ventricular flutter / sinusoidal rhythm → asystole

V5



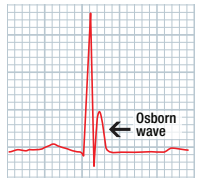
HYPOKALEMIA: **prominent U wave**; ST depression; flat T wave; ↗ QT interval; blocks; atrial - ventricular - junctional tachyarrhythmias / Torsade de pointes

V5



HYPOTHERMIA (< 34°C): Osborn wave; bradycardia; ↗ QT interval; ↗ QRS duration; ↗ PR interval; artefacts secondary to rigors; junctional bradycardia; ventricular arrhythmia; asystole

› **Osborn wave**: notch and elevation of J point (maximal in V5-V6)



HYPOTHYROIDISM: low voltage; sinus bradycardia; flat T wave; ↗ PR interval; conduction disorders; ↗ QT interval

1.3/ STRESS TEST

INDICATION

INDICATION FOR STRESS TEST

DIAGNOSTIC
Intermediate pretest probability of CAD
(stop anti-ischemic medication 5 half-lives before the test)

and/or

PROGNOSTIC
Known CAD or intermediate or high probability of CAD

	SENSITIVITY	SPECIFICITY
General population	68 %	77 %
LMCA or 3–vessel disease	86 %	53 %

CONTRAINDICATIONS

ABSOLUTE	RELATIVE
• Acute infarction ≤ 48 h • High-risk unstable angina • Decompensated heart failure • Uncontrolled arrhythmia with symptoms or hemodynamic instability • Myocarditis or acute pericarditis • Severe symptomatic aortic stenosis • Acute pulmonary embolism • Acute aortic dissection	• Left main coronary artery stenosis • Moderate stenotic valvular heart disease • Electrolyte disorders • Severe HTN: > 200/110 mmHg • Tachyarrhythmia or bradyarrhythmia • HCM • Advanced AV block • Mentally unable to perform the exercise **ANOMALIES ON BASELINE ECG** • Pre-excitation • LBBB • Ventricular pacing • ST depression > 1 mm • Digoxin and LVH with repolarization abnormalities (false-positive)

COMPLICATIONS: 3.5 infarctions - 4.8 arrhythmias - 0.5 deaths per 10,000 examinations performed

PROTOCOLS

7	12.5	3	14	28	8

1 MET: = **3.5 mL O_2/kg/min** (O_2 consumption in a resting subject)

ESTIMATED VO_2: = [(2.68 x mph) x (0.1 + (% slope x 1.8))] + 3.5

MONITORING: **ECG - HR - BP - Rating of perceived exertion (Borg scale)** at the end of each stage; at the end of exercise; every 2-3 min during recovery (for 6-10 min or normalization of ECG)

BRUCE PROTOCOL: change of speed and slope at each 3-min stage; modified Bruce with the addition of 2 initial stages if necessary

CORNELL PROTOCOL: more gradual increase of exertion (each Bruce stage is subdivided into 2 substages)

NAUGHTON PROTOCOL: 2-min stages; increase of 1 MET per stage; used during evaluation of VO_2 max

RAMP PROTOCOL: the slope and speed increase progressively according to the patient's previously estimated functional class (according to an activity scale expressed in METs) to achieve exercise lasting about 8 to 12 minutes

POST-INFARCTION: **A)** Prescription of physical activity; **B)** Effects of treatment; **C)** Prognostic value (unknown coronary anatomy)

- **Submaximal stress test (3-4 days):** Modified Bruce or Naughton; stop if HR ≥ 120 bpm or ≥ 70% of predicted HRmax or 5 METs or Angina or Dyspnea or ↘ ST 2 mm or ↘ BP or ≥ 3 consecutive PVCs
- **Stress test limited by symptoms (3 weeks):** standard test

ELECTROCARDIOGRAPHIC EVALUATION

ST SEGMENT: depression compared to PQ segment, **80 ms from point J (ST80)** or 60 ms from point J if HR > 130 bpm (ST60)

Normal response: ascending ST depression	• ST80 depression < 1.0 mm • Ascending slope ≥ 1 mV/s (1 mV = 10 mm)	Abnormal response: horizontal ST depression	• J and ST80* depression ≥ 1 mm • Horizontal slope (< 0.7 to 1 mV/s)	Abnormal response: descending ST depression	• J and ST80* depression ≥ 1 mm • Descending slope (< -1 mV/s)	Gray zone: ST depression with slow rise	• ST80 depression ≥ 1.0 mm • Ascending slope ≥ 1 mV/s • Evaluate according to the patient's pretest probability of CAD	Transmural ischemia: ST elevation	• J and ST60 elevation ≥ 1 mm • Absence of Q wave • Localize ischemia	
* ST60 if HR > 130 bpm

MORE SPECIFIC LEADS: **V4-V5-V6**; isolated ST abnormalities in II and aVF often associated with false-positive results

ST DEPRESSION: does not localize the ischemia

ST ELEVATION IN AVR: associated with left main coronary / ostial LAD stenosis

U WAVE INVERSION: associated with significant CAD

BASELINE RBBB: ignore leads V1-V2-V3-V4 during the stress test

FALSE-POSITIVE: baseline ST abnormality; anemia; cardiomyopathy; Digoxin; hyperventilation; hypokalemia; intraventricular conduction disorders; LVH; pre-excitation; severe AS; severe HTN; severe hypoxia; severe volume overload; supraventricular tachycardia; MVP

INDICATIONS TO TERMINATE THE TEST

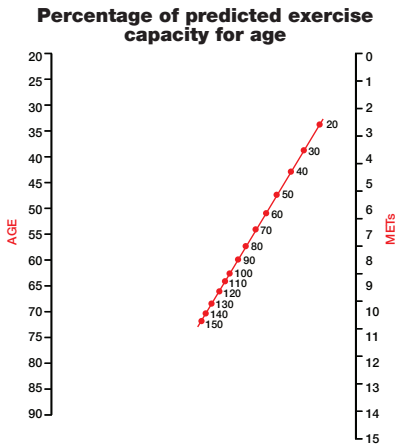
ABSOLUTE	RELATIVE
• ↘ BP ≥ 10 mmHg with ischemia • Severe and intolerable angina (CCS 3 to 4/4 on tolerance scale) • Ataxia; Faintness • Hypoperfusion (cyanosis; pallor) • Technical difficulty • Patient wants to stop • Sustained VT • ST elevation: ≥ 1 mm (in absence of Q wave and elsewhere than in aVR or V1)	• ↘ BP ≥ 10 mmHg • ST depression: > 2 mm • Marked change of QRS axis • Arrhythmia: polymorphic PVCs; triplet PVCs; supraventricular tachycardia; block; bradyarrhythmia • Fatigue - Dyspnea - Wheezing - Leg cramps - Claudication • Intraventricular conduction disorder unable to be distinguished from VT • Worsening retrosternal chest pain • Exaggerated hypertensive response: BP > 250/115

OTHER ELEMENTS TO BE EVALUATED

NON-DIAGNOSTIC TEST: **insufficient exercise (< 85% of predicted HRmax for age)**

› **Predicted HRmax for age**: **= 220 - age**

MAXIMUM FUNCTIONAL CAPACITY: # METs; powerful prognostic marker



Source: *Morris CK, Myers J, Froelicher VF, et al. JACC 1993; 22; 175-182.*

DOUBLE PRODUCT: HR x SBP / 1000 (normal: 20-35 mmHg x bpm x 10^{-3})

ANGINA: generally occurs after ST abnormalities

SYSTOLIC BLOOD PRESSURE: peak generally observed between 160 and 200 mmHg

- **Abnormal response**: failure to reach 120 mmHg or ↘ > 10 mmHg or ↘ below baseline SBP; associated with significant ischemia or cardiomyopathy or LVOT obstruction or antihypertensive medication or significant dehydration
- **Exaggerated hypertensive response**: SBP > 210 mmHg in men or > 190 mmHg in women; risk of developing HTN in the future in a currently normotensive patient; indicates an insufficient reduction of systemic vascular resistance by arteries and arterioles during exercise; ABPM may be indicated

CHRONOTROPIC INCOMPETENCE: failure to achieve > 80-85% of predicted HRmax for age (with significant exercise); associated with poor prognosis

- **Chronotropic index**: observed HR reserve (maximum HR on stress test - HR at rest) / (predicted HRmax for age - HR at rest); chronotropic incompetence if **< 80 %**

DE NOVO LBBB ON EXERTION: associated with ↗ risk of mortality and significant CAD

RECOVERY OF HR AT 1 MIN: = peak HR - HR after 1 minute of rest

- **Abnormal HR recovery:** < 12 bpm (standing) or 18 bpm (supine); associated with poor prognosis

PVCS DURING RECOVERY: associated with ↗ risk of mortality (compared to patients with PVCs on exertion only)

DUKE TREADMILL SCORE (DTS)

DTS = EXERCISE TIME (MIN) - (5 X MAXIMUM ST DEPRESSION IN MM) -4 X (ANGINA SCORE)	
ANGINA SCORE • Angina requiring termination = 2 • Angina not requiring termination = 1 • No angina = 0	**ONE-YEAR MORTALITY** • DTS -11 and less: 5.0% • DTS between +4 and -10: 1.25% • DTS ≥ +5: 0.25 %

Mark DB, Hlatky MA, Harrell FE Jr et al. Ann Intern Med. 1987; 106:793.

FACTORS OF POOR PROGNOSIS

DUKE TREADMILL SCORE: -11 and less +

LOW FUNCTIONAL CAPACITY: < 5 METs +

LOW THRESHOLD ANGINA OR ISCHEMIA: < 70% predicted HRmax or HR < 120 bpm or ≤ 4 METs +

SEVERE ST DEPRESSION: ≥ 2 mm +

MULTIPLE LEADS: ischemia on ≥ 5 leads +

PERSISTENCE: ischemia ≥ 3 min during recovery +

ST ELEVATION: ≥ 1 mm (except for aVR) +

ABNORMAL BP RESPONSE: failure to achieve 120 mmHg or ↘ > 10 mmHg or ↘ below baseline SBP

SUSTAINED OR SYMPTOMATIC VT

Mean PAP (mmHg)	• **mPAP = 1/3 sPAP + 2/3 dPAP** • **mPAP = 4 x early diastolic PR velocity² + RA pressure** • **Mahan: mPAP = 79 – (0.45 x PA acceleration time)** › If PA acceleration time < 120 ms: mPAP = 90 - (0.62 x PA acceleration time) › **PA acceleration time**: start of QRS to peak pulmonary flow velocity; pulsed Doppler			
Pulmonary artery diameter (mm)	15-21	22-25	26-29	≥ 30

DIASTOLIC FUNCTION

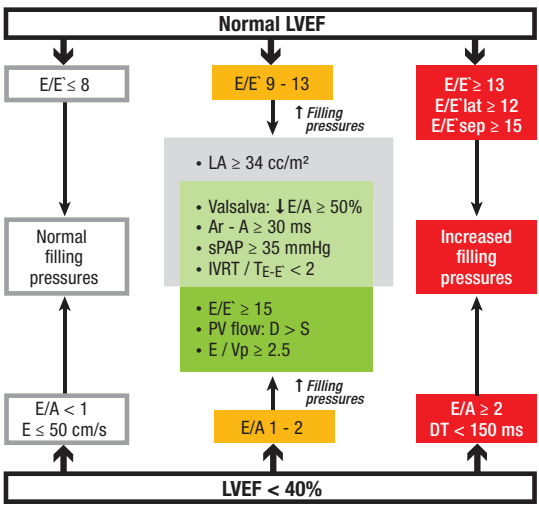
	DIASTOLIC FUNCTION - GRADING				
	E` (cm/s) E/E`	**LA (mL/m²)**	**E/A DT (ms) IVRT (ms)**	**PV FLOW AR - A (ms)**	**VALSALVA**
NORMAL PATTERN	E`sep ≥ 8 E`lat ≥ 10 E/E`≤ 8 	< 34	E/A 0.8 - 1.5 DT 160-200 	PV S > D Ar - A < 0 	Reduction of E/A ratio < 0.5
GRADE I: ABNORMAL RELAXATION PATTERN	E`sep < 8 E`lat < 10 E/E`≤ 8 	≥ 34	E/A < 0.8 DT > 200 IVRT ≥ 100 	PV S > D Ar - A < 0 	Reduction of E/A ratio < 0.5
	Normal filling pressures (generally)				
	> 60 years: E/A < 1 and DT > 200 ms in the absence of LVH or heart disease → normal for age				
GRADE II: PSEUDO-NORMAL PATTERN	E`sep < 8 E`lat < 10 E/E` 9-12 	≥ 34	E/A 0.8 - 1.5 DT 160-200 	VP D > S Ar - A ≥ 30 	Reduction of E/A ratio ≥ 0.5
	↗ Filling pressures				

GRADE III: RESTRICTIVE PATTERN	E`sep < 8 E`lat < 10 E/E`> 13 E/E`sep ≥ 15 E/E`lat > 12 	≥ 34	E/A ≥ 2 DT < 160 IVRT ≤ 60	PV D > S Ar - A ≥ 30 	Variable
	↗↗↗ Filling pressures **DDx**: Severe decompensated heart failure; advanced RCM; severe CAD; severe acute AR; Constrictive pericarditis				
	IIIa: filling pattern improves in response to treatment **IIIb**: absence of improvement of the filling pattern in response to treatment				

IVRT: Continuous Doppler LVOT; interval between end of Ao ejection and start of mitral filling (E wave)

FUSION OF E AND A: E wave > 20 cm/s at the beginning of the A wave

FILLING PRESSURES



- **Increased filling pressures**: Wedge pressure > 12 mmHg or LVEDP > 16 mmHg
- **TE-E`**= (interval between QRS and onset of E) - (interval between QRS and onset of E`)
- **Vp**: velocity of propagation of diastolic flow on color M-mode
- **AF**: ↗ filling pressures if **IVRT ≤ 65 ms or DT of pulmonary vein diastolic flow ≤ 220 ms or septal E/E' ≥ 11**

SEGMENTAL WALL MOTION

LEFT VENTRICLE: **divided into 16 segments** (+ apical cap)

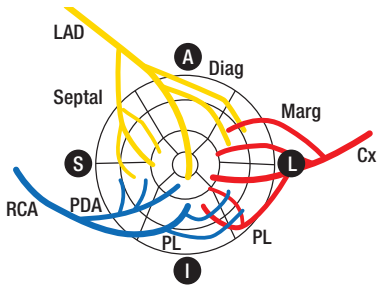
› **Interventricular septum**: between the attachments of the RV to the LV

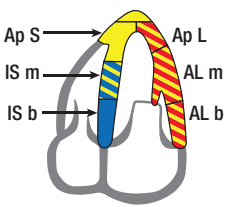
LEFT VENTRICULAR CHAMBER: **3 levels → A) Base - B) Mid 1/3 (papillary muscles) - C) Apex**

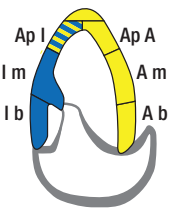
SEGMENTAL WALL MOTION: **evaluate endocardial excursion and segmental thickening** +

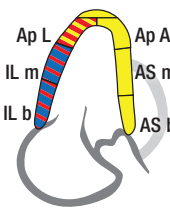
– 1 – NORMAL (or hyperdynamic)	– 2 – HYPOKINESIA	– 3 – AKINESIA	– 4 – DYSKINESIA	– 5 – ANEURYSM
Thickening > 40% in systole	Thickening 10-40%	Thickening < 10% (negligible)	Paradoxical systolic movement	Diastolic deformity

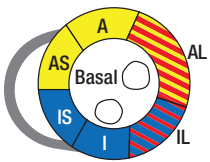
WMSI = Sum of each segment / Number of segments evaluated
Normal = 1; WMSI > 1.7 associated with perfusion defect > 20% (MIBI)

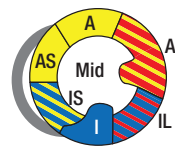


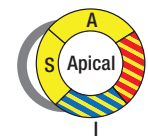












AORTIC STENOSIS		SEVERE
Maximum jet velocity	Look for parallel alignment between continuous Doppler and the jet	**> 4 m/s**
Mean gradient	Mean of instantaneous mean gradients during ejection	**> 40 mmHg**
Valve area by continuity equation	**Aortic valve area = 0.785 x LVOT diameter² x LVOT VTI / Aortic valve VTI**	**< 1 cm²**
	• LVOT VTI and LVOT diameter obtained at the same distance from the valve • **Proximal velocity (LVOT) > 1.5 m/s**: use peak velocity and maximum gradient to grade severity **› Maximum gradient = 4 (maximum v² – proximal v²)**	
LVOT VTI / Ao valve VTI ratio	Independent of measurement of LVOT	**< 0.25**
Velocity > 4 m/s and Area > 1 cm²: high output; significant AR; tall patient **Velocity < 4 m/s and Area < 1cm²:** low output; small patient; significant MR		

MITRAL STENOSIS		SEVERE
Mean gradient	Mean of instantaneous mean gradients during filling	**> 10 mmHg**
Valve area by planimetry	• Method of choice in rheumatic MS • At the extremity of the leaflets (PSAX)	**< 1 cm²**
Valve area by pressure half-time	**Mitral valve area = 220 / PHT**	**< 1 cm²**
	• Use the slope of the E wave at mid-diastole • Method of choice in rheumatic MS • **Caveats**: immediately after balloon valvuloplasty; severe AR (short PHT); abnormal LV relaxation (long PHT); ↗ LVEDP (short PHT); prosthetic valve (do not calculate prosthetic area but report PHT)	
Valve area by continuity equation	**Mitral valve area = 0.785 x LVOT diameter² x LVOT VTI / mitral valve VTI**	**< 1 cm²**
Valve area by PISA	**Mitral valve area = [6.28 x PISA radius x Aliasing velocity / Peak MS velocity] x alpha/180°**	**< 1 cm²**

INDICATE HR AT THE TIME OF MEASUREMENTS; EVALUATE PAP

BVR SCORE – BALLOON VALVULOPLASTY REGISTRY (WILKINS SCORE)				
	– 1 – Mobility of leaflets	**– 2 – Thickening of leaflets**	**– 3 – Calcification of leaflets**	**– 4 – Thickening of subvalvular apparatus**
1 point	Very mobile valve; restriction of the extremity of the leaflets	Leaflets measure 4-5 mm	A single hyperechodense zone	Minimal thickening under the leaflets

2 points	Normal mobility of the base and middle parts of the leaflets	Localized thickening (5-8 mm)	Several localized hyperechodense zones on the leaflets	Thickening of the chordae (1/3 of their length)
3 points	Mobility of the base of the valve	Thickening of all of the leaflet (5-8 mm)	Hyperechodensities as far as the middle portion of the leaflets	Thickening of the chordae as far as their distal third
4 points	Minimal or absent movement of the leaflets	Considerable thickening of the entire leaflet (8-10 mm)	Extensive hyperechodensities on the majority of the leaflets	Severe thickening as far as the papillary muscles

Score ≤ 8 associated with a favorable result of balloon valvuloplasty

MITRAL REGURGITATION		SEVERE
Vena contracta	Narrowest portion of the jet distal to the regurgitating orifice; avoid AP2C; Nyquist 50-60 cm/s	**≥ 7 mm**
Regurgitant volume	**VOLUMETRIC METHOD** Regurgitant volume = (0.785 x Mitral annulus diameter ² x anterograde mitral VTI) - (0.785 x LVOT diameter ² x LVOT VTI) • **Mitral annulus diameter**: mean of PLAX and AP4C • **Significant AR**: use pulmonic valve flow **PISA**: Regurgitant volume = EROA x MR VTI	**≥ 60 cc**
EROA (Effective Regurgitation Orifice Area)	**VOLUMETRIC METHOD** EROA = Regurgitant volume / MR VTI **PISA** EROA = 6.28 x PISA radius ² x "aliasing" velocity / peak MR velocity  • PISA corresponds to the time of peak MR velocity • "Aliasing" velocity adjusted to the direction of regurgitation to obtain hemispheric convergence flow (Nyquist 20-40 cm/s)	**≥ 0.40 cm²** **(≥ 0.20 cm² if functional MR)**
Regurgitant fraction	Regurgitant fraction = Regurgitant volume / (0.785 x Mitral annulus diameter ² x anterograde mitral VTI)	**≥ 50 %**
PISA radius	Nyquist 40 cm/s	**≥ 9 mm**
MR jet	• Nyquist 50-60 cm/s • **Severe MR:** Large central jet > 10 cm² (or > 40% LA area) or eccentric jet adhering to the wall of the LA (Coanda effect)	

E wave	Dominant E wave	**> 1.2 m/s**
Envelope of the jet on continuous Doppler	• **Severe MR**: dense envelope; early peak and triangular shape • **MVP:** mid- or end-systolic envelope	
Pulmonary venous flow	**Severe MR**: systolic reversal	
LA dilatation and LV dilatation; Carpentier's mechanism		

AORTIC REGURGITATION		**SEVERE**
Vena contracta	Narrowest portion of the jet distal to the regurgitating orifice; PLAX; Nyquist 50-60 cm/s	**≥ 6 mm**
Regurgitant volume	**VOLUMETRIC METHOD** Regurgitant volume = (0.785 x LVOT diameter ² x LVOT VTI) - (0.785 x Mitral annulus diameter ² + anterograde mitral VTI) • **Mitral annulus diameter**: mean of PLAX and AP4C • **Significant MR**: use pulmonic valve flow **PISA**: Regurgitant volume = EROA x AR VTI	**≥ 60 cc**
EROA (effective regurgitation orifice area)	**VOLUMETRIC METHOD** EROA = Regurgitant volume / AR VTI **PISA** EROA = 6.28 x PISA radius ² x "aliasing" velocity / peak AR velocity	**≥ 0.3 cm²**
Regurgitant fraction	**Regurgitant fraction = Regurgitant volume / (0.785 x LVOT diameter ² x LVOT VTI)**	**≥ 50 %**
Jet width / LVOT diameter	PLAX; 1 cm inside the Ao valve; Nyquist 50-60 cm/s	**≥ 65 %**
Jet area / LVOT area	PSAX	**≥ 60 %**
Pressure half-time	• Continuous Doppler • End-diastolic speed > 4 m/s • ↘ **PHT**: HTN; ↘ LV compliance; ↗ LVEDP	**< 200 ms**
Envelope of the jet on continuous Doppler	**Severe AR**: dense envelope (compare with density of the anterograde flow); rapid deceleration	
Holodiastolic flow reversal in descending aorta	• Pulsed Doppler (after the origin of the L subclavian) • Also look for reversed flow in abdominal aorta • **Reversal VTI ≈ anterograde flow VTI** 	
LV dilatation; Ao dilatation; look for eversion or malcoaptation of leaflets; severe acute AR → restrictive mitral filling pattern		

PROSTHETIC VALVE

LOOK FOR: normal 60° opening of leaflets (normal movement of acoustic shadows); dehiscence / rocking movement; vegetation; thrombus; pannus; structural degeneration; abscess; intracardiac mass; pseudoaneurysm; fistula; periprosthetic regurgitation

- **Thrombus**: large mass; similar density to that of myocardium; recent symptoms; recent subtherapeutic INR; more frequent on mechanical mitral valve prosthesis
- **Pannus**: small, dense mass; not visualized in 30% of cases; more frequent in aortic valve prostheses

PROSTHETIC VALVE HEMODYNAMIC MEASUREMENTS: vary according to the model and dimensions of the prosthesis (compare with manufacturer's data); vary according to cardiac output

RECOVERY PRESSURE PHENOMENON: Ao transprosthetic gradient overestimated on TTE compared to catheterization (especially if proximal aortic diameter < 30 mm and small prosthesis)

PROSTHETIC REGURGITATION: distinguish physiological regurgitation specific to the prosthesis from pathological regurgitation; metallic mitral valve can hide MR due to shadowing

- **Central pathological regurgitation**: immobility of a mechanical leaflet; prolapse or perforation of a biological leaflet; mass - vegetation - thrombus
- **Periprosthetic pathological regurgitation:** dehiscence; rocking movement

PATIENT-PROSTHESIS MISMATCH: area of the effective prosthetic orifice too small for the patient's body surface area; **valve functions normally but with ↗ transvalvular gradients; normal prosthetic area (non-indexed) for the type of prosthesis**

- **Mild**: Indexed EOA > 0.85 cm²/m²
- **Moderate**: Indexed EOA: 0.65-0.85 cm²/m²
- **Severe**: Indexed EOA < 0.65 cm²/m²; associated with ↗ mortality (especially if LV dysfunction)
- **Mitral prosthesis:** aim for indexed EOA > 1.2 cm²/m²

	PROSTHETIC AORTIC VALVE DYSFUNCTION		
	PEAK VELOCITY	**VTI 1/2 RATIO**	**ACCELERATION TIME (AORTIC SYSTOLIC FLOW)**
Obstruction (degeneration; thrombus; pannus)	> 3 m/s	< 0.25	> 100 ms Delayed and parabolic peak
Regurgitation or ↗ cardiac output	> 3 m/s	Normal (≥ 0.25)	AT < 80 ms Early triangular peak
Patient-prosthesis mismatch	**Indexed EOA < 0.85 cm²/m²**		
	> 3 m/s	≥ 0.25	AT < 80 ms

	PROSTHETIC MITRAL VALVE DYSFUNCTION			
	PEAK VELOCITY	**GRADIENT**	**PHT**	**PROSTHETIC MITRAL VALVE VTI / LVOT VTI RATIO**

Hyperdynamic state / High output state	≥ 1.9 m/s	> 5 mmHg	< 130 ms	< 2.2 (normal)

ECHOCARDIOGRAPHIC MASS

MASSES / STRUCTURES: Eustachian valve / crista terminalis bridge / Chiari network (RA); vegetation; thrombus; degenerative valve disease; calcification; pacemaker lead; central catheter; lipomatous interatrial septum; pericardial cyst; hydatid cyst; hiatal hernia; tuberculoma; Lambl's excrescences / valvular strands (filiform structures; lenght 3-10 mm; atrial aspect of AV valves and ventricular aspect of semilunar valves; on the line of leaflet closure); benign or malignant cardiac tumor (or metastasis)

THROMBUS: absence of opacification with contrast; adherent to a hypokinetic or akinetic region

CONTRAST ECHOCARDIOGRAPHY

AGITATED SALINE: 10 mL of saline solution; 0.25 mL of air emulsified with 2 syringes; right heart imaging

- **Intracardiac shunt**: **opacification of L chambers within 3 beats** (± Valsalva) +
- **Intrapulmonary shunt (AVMs)**: **opacification of L chambers after 5 beats** +
- **Persistent left SVC:** injection into left arm → opacification of coronary sinus

MICROBUBBLES: lipid microspheres containing gas and able to cross the pulmonary circulation allowing visualization of left cardiac structures; useful for LVEF - segmental wall motion - stress echocardiography - L chamber mass / thrombus (no enhancement in the presence of thrombus) - aneurysm / pseudoaneurysm - HCM - LV noncompaction

- **Complications**: 0.01 %
- **Contraindications**: perflutren allergy; significant PHT; R → L shunt
- **Microbubbles mode**: reduction of mechanical index (0.4-0.5)

TISSUE AND STRAIN DOPPLER

TISSUE DOPPLER IMAGING (TDI): evaluates the velocity of longitudinal movement of a cardiac structure (low velocities); angle dependant

STRAIN (%): longitudinal deformation evaluation; percentage change in length of the muscle during contraction (negative value by convention) or relaxation (positive value by convention)

STRAIN RATE: instantaneous measurement of the deformation (contraction or relaxation)

TISSUE TRACKING: distance covered (displacement) by a structure over a given time interval

TISSUE DOPPLER (S WAVE) (CM/S)	SYSTOLIC STRAIN (%)	STRAIN RATE (S^{-1})	TISSUE TRACKING (cm)
Normal basal septum: 5.97 ± 1.14	Normal basal septum: -17.5 ± 5.32	Normal basal septum: 0.99 ± 0.49	Normal basal septum: 1.2 ± 0.19

SPECKLE TRACKING: evaluation of the deformation of a structure; angle-independent, which allows measurement of longitudinal, radial or circumferential deformation (counterclockwise systolic movement of the apex and clockwise systolic movement of the base)

- **Global longitudinal strain (%)**: relative length change of the LV myocardium between end-diastole and end-systole **(normal peak GLS in the range of -20%)** +

1.5/ TRANSESOPHAGEAL ECHOCARDIOGRAPHY (TEE)

EVALUATION: mitral valve; aortic valve; prosthetic valve; endocarditis; LA; LAA - thrombus (pre-ECV); intracardiac mass; ASD; acute aortic syndrome; pulmonary venous return; perioperative; cardioembolic source; guidance of percutaneous procedures

COMPLICATIONS: < 1%; dental trauma; esophageal trauma; bronchospasm; laryngospasm; aspiration; respiratory depression; arrhythmias; methemoglobinemia (benzocaine)

PREPARATION

- **Contraindications**: dysphagia; esophageal disease; recent esophageal symptoms; esophageal varices; history of radiotherapy to the neck
- **NPO:** minimum 6 hours before the examination (H_2O allowed until 2 hours before the examination)
- Continuous ECG; IV route; O2; saturation and BP monitor; suction
  - Resuscitation trolley at hand
  - Flumazenil 0.2 mg IV PRN (benzodiazepine antagonist); Naloxone 0.1 to 0.4 mg IV PRN
- **Anesthesia:** topical (lidocaine); IV sedation (midazolam 0.075 mg/kg, i.e. 2-4 mg; fentanyl PRN); Meperidine PRN (anti-gag; 25-50 mg IV)

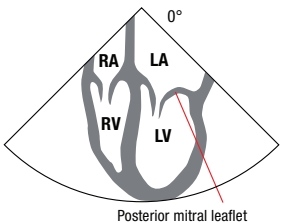
POST-EXAMINATION: NPO 2 hours post-examination; no driving for 12 hours

5 POSSIBLE MOVEMENTS

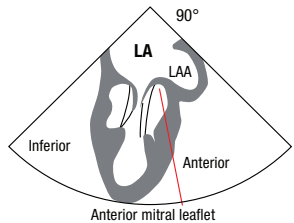
1) Advance - withdraw the probe
2) Rotation of the plane of section (0 degree = horizontal; 90 degrees = vertical)
3) Rotation of the hand piece: clockwise (R heart) or counterclockwise (L heart)
4) Anteflexion (bending of the tip of the probe toward the sternum) or retroflexion
5) Lateral flexion to the right or left (rarely used)

INFERIOR TRANSESOPHAGEAL (30–35 CM)

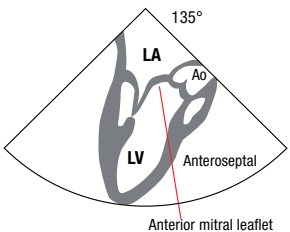
4 CHAMBERS - 0°



2 CHAMBERS - 90°



LONG AXIS - 135°

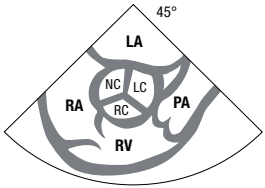


LEFT ATRIAL APPENDAGE

- **45° on mitral valve**: LAA to the right on the screen
  - Progressive rotation of the plane to evaluate the LAA (± slight withdrawal of the probe)
- **Rule out intra-LAA thrombus** (circumscribed mass; bright; uniform texture and different from that of the LA wall)
- **Intra–appendicular velocities (Pulsed Doppler):** < 20 cm/s **associated with a risk of thromboembolic events**
- **Look for spontaneous echo contrast** (prothrombotic state)

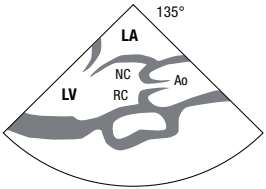
SUPERIOR TRANSESOPHAGEAL

SHORT AXIS (AORTIC VALVE) – 45°



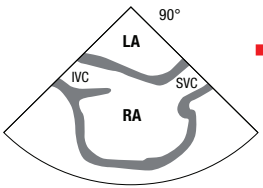
- **Coronary ostia:** 2 o'clock (left) and 6 o'clock (right)
- **Pulmonary valve and PA:** 100-130° ± counterclockwise rotation

LONG AXIS – 135°



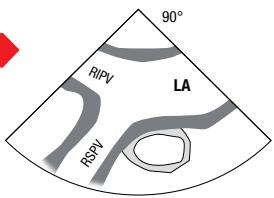
- NC = Non-coronary aortic leaflet
- RC = Right coronary aortic leaflet

BICAVAL VIEW – 90°



- Clockwise rotation of the hand piece
- Longitudinal interatrial septum
- **Rule out shunt**: Color Doprler (Nyquist 30-40 cm/s); agitated saline (± Valsalva)
- Pacemaker lead; central catheter

PULMONARY VEINS – 90°



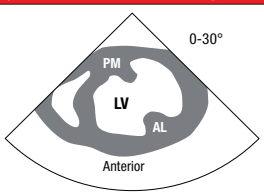
- On the bicaval view → clockwise rotation of the hand piece
- Counterclockwise rotation of the hand piece: left pulmonary veins (adjacent to the LAA)

LEFT PULMONARY VEINS

- **LSPV**: position the probe over the LAA (next to LSPV); slight withdrawal of the probe + anteflexion + counterclockwise rotation of the hand piece (± rotation of the plane)
- **LIPV:** after having localized the LSPV, look for the LIPV by counterclockwise rotation of the hand piece and/or progressive rotation of the plane

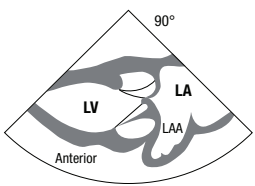
TRANSGASTRIC

SHORT-AXIS LV (MITRAL PAPILLARY MUSCLES) 0–30°



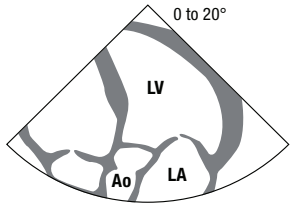
Mitral valve, short axis: slightly withdraw the probe + slight anteflexion + 10-20°

2 CHAMBERS – 90°



110–135°: long axis (LVOT - Ao valve)

5 CHAMBERS (DEEP TRANSGASTRIC) – 0 to 20°



- Maximum anteflexion
- Evaluation of LVOT

DESCENDING THORACIC AORTA

- Counterclockwise rotation of the hand piece
- 0°: short axis; 90°: long axis
- **Complex atherosclerosis**: plaque thickness ≥ 4 mm or mobile / pedunculated debris (= thrombus) or ulceration

MITRAL REGURGITATION - NATIVE VALVE

MECHANISM: Carpentier classification (▶▶| Chapter 4 - Valvular heart disease); prolapse; eversion; restriction; annular dilatation; perforation

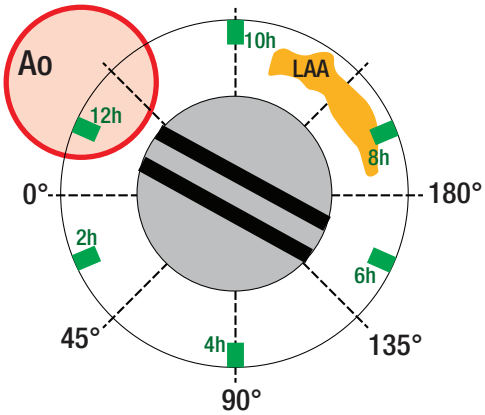
IDENTIFICATION OF THE SEGMENTS INVOLVED

- **A1-P1**: anterolateral
- **A3-P3:** posteromedial

STEP 1 **Transesophageal inferior 4 chambers (0°)**	 Baseline image	 Anteflexion or withdrawal of the probe	 Probe advanced or retroflexion
STEP 2 **Transesophageal inferior 70° (parallel to long axis of mitral valve)**	 Baseline image	 Clockwise rotation of hand piece	 Counterclockwise rotation of hand piece

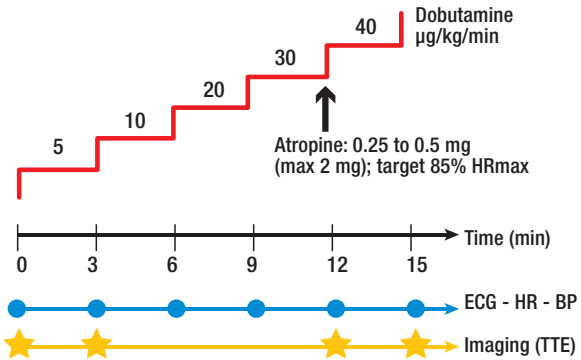
MITRAL REGURGITATION - PROSTHETIC VALVE

IDENTIFICATION OF THE SURGICAL QUADRANT: transesophageal 4 chambers (0); rotation of the plane of section every 10° for 180°



1.6/ STRESS ECHOCARDIOGRAPHY

STRESS: exercise (Bruce protocol) or Dobutamine



INDICATIONS TO STOP DOBUTAMINE STRESS ECHOCARDIOGRAPHY: > 85 % HRmax predicted for age; moderate *de novo* (or progressive) RWMA; significant arrhythmia; hypotension; severe HTN; intolerable symptoms

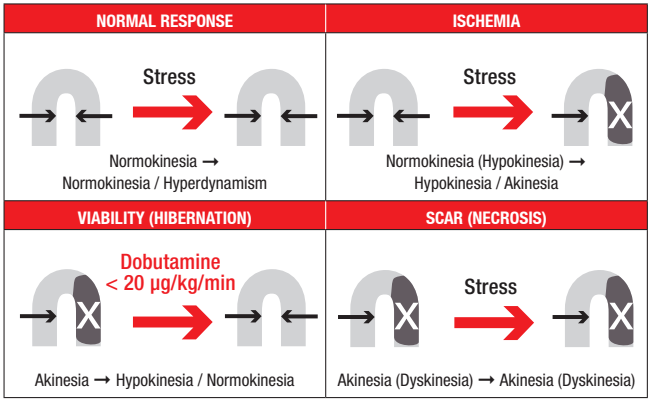
› **Antidote to dobutamine:** beta-blocker

COMPLICATIONS (DOBUTAMINE): angina; hypotension; VT (4%); supraventricular tachyarrhythmia / AF; VF or myocardial infarction (1 / 2,000 studies)

CONTRAST AGENT: ≥ 2 segments poorly visualized on baseline TTE

STRESS-INDUCED ISCHEMIA

a) **RWMA (regional wall motion abnormality):** deterioration ≥ 1 grade of segmental wall motion (normokinetic or hypokinetic segment at rest); deterioration of endocardial excursion and/or segmental thickening
b) **Tardikinesia**: delayed and slow segmental contraction
c) **Chamber dilatation:** ↗ end-systolic LV volume
d) **↘ LVEF:** deterioration of global systolic function



SCAR: regional wall motion abnormality unchanged by stress test (fixed deficit); thin < 6 mm and echodense (fibrotic) segment

DECREASED PREDICTIVE VALUE: target HR not achieved; LVH / concentric remodeling; imaging > 60 s post-stress; 1-vessel disease (particularly circumflex); LBBB; ventricular pacing

FINDINGS IN REPORT: type of stress protocol; result of stress test or dose of dobutamine used; maximum HR reached; test validity (> 85% HRmax); BP; reason for interruption; symptoms on stress test; ECG abnormalities; arrhythmias; ischemic threshold; segmental wall motion at rest and on stress test; LVEF and end-systolic LV volume at rest and on stress test

FACTORS OF POOR PROGNOSIS

- **Resting LVEF:** < 35 %
- **Low ischemic threshold:** dobutamine ≤ 10 µg/kg/min or < 70% HRmax predicted or HR < 120 bpm
- **WMSI on effort:** > 1.4 to 1.7
- **Extensive ischemia:** ≥ 3 segments
- **Ischemia in several coronary territories (≥ 2 vessels)**
- **Deterioration of LVEF (< 45% or ↘ LVEF ≥ 10%) or LV dilatation on stress test**

NEGATIVE STRESS ECHOCARDIOGRAPHY: annual risk of cardiac event < 1% (exercise) or < 2% (dobutamine)

VIABILITY: improvement of the segmental wall motion (≥ 1 grade x ≥ 2 segments) with low-dose dobutamine (2.5 - 5 - 7.5 - 10 - 20 µg/kg/min)

- **Biphasic response**: improvement of wall motion at low-dose then deterioration at higher dose (up to 40 µg/kg/min); specific for improvement of wall motion post-revascularization
- **Sustained improvement**: viable but non-ischemic segment

1.7/ CHEST X-RAY

QUALITY CONTROL: **A)** Patient - Date; **B)** Adequate inspiration (right hemidiaphragm below the 6th rib anteriorly and below the 10th rib posteriorly); **C)** Patient centered - Absence of rotation (tracheal air column in the center of the vertebral bodies; spinous processes of vertebral bodies centered between clavicles); **D)** Adequate penetration (spinous processes of thoracic vertebral bodies visible); **E)** Compare with previous films

SYSTEMATIC APPROACH: Situs (gastric bubble and apex); Cardiothoracic index; Heart shadow and cardiac structures (RA; LA; RV; LV; Ao; PA); Calcifications; Pulmonary venous and arterial blood supply; Hila; Lung parenchyma; Pleura; Bone structures; Prosthetic material

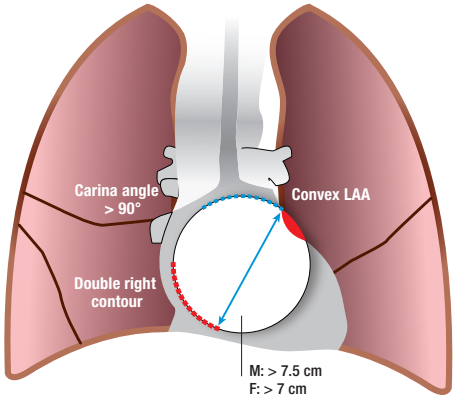
to the IVC

CARDIOTHORACIC INDEX (PA): < 0.5

› **False-positive**: AP film; Obesity; Pregnancy; Pectus excavatum; Ascites; Scoliosis; Under-inspiration

LA DILATATION: convexity of the LAA (between LPA and LV); quadruple contour (Ao; PA; LAA; LV); elevation of left main bronchus (carina angle > 90°); right double contour; posterior dilatation on lateral film



RA DILATATION: right shadow shifted towards the right; ± dilatation of SVC - IVC - azygos vein secondary to ↗ CVP

RV DILATATION: **transverse displacement of the left shadow**; **RV > 1/3 of the distance between the cardiophrenic angle and the sternal angle (lateral film)**; ± PA dilatation

› **DDx of filling of retrosternal space**: post-sternotomy; lymphadenopathy; mediastinal mass (lymphoma; thymoma; thyroid); pulmonary trunk dilatation; aortic root dilatation; small antero-posterior diameter (pectus excavatum; scoliosis; kyphosis)

LV DILATATION: prominent apex displaced downwards; downward displacement of gastric bubble and posterior displacement of LV (> 1.8 cm with respect to IVC) on the lateral film

PA DILATATION: L⟶R shunt; post-stenotic dilatation (main PA and LPA); Pulmonary hypertension (venous or arterial); PR; idiopathic

› **RPA dilatation**: > **17 mm**
› **Main PA dilatation**: prominence between the aortic knob and the LAA

ASCENDING AORTA DILATATION: prominent right contour of mediastinum; prominent anterior contour of mediastinum on lateral film; distance between left lateral edge of tracheal air column and aortic knob > 35 mm

NORMAL PULMONARY BLOOD SUPPLY: peripheral attenuation (distal 1/3 not visible); vessels at base > vessels at lung apex

› **Venous congestion (venous PHT)**: redistribution to apices (cephalization); blurred peripheral vessels; Kerley B lines (1-3 cm long; 1 mm thick; horizontal; arising from pleura); interstitial edema; peribronchial edema; prominent and blurred hila; edema of fissure; pleural effusions; alveolar edema; PA dilatation
  • **Dilatation of azygos vein (>1 cm)**: Right heart failure (↗ CVP); SVC obstruction; Constrictive pericarditis; IVC interruption (venous return via azygos system); anomalous PV connection

- **Peripheral hypervascularization** (vessels visible below the diaphragm)
  a) **L→R shunt**: Dilated PA; branches of PA > associated bronchi; dilatation of heart chambers
  b) **High output state**: pregnancy; hyperthyroidism; anemia
- **Peripheral hypovascularization**
  a) **PHT**: RVH; PA - LPA - RPA dilatation; **early and marked attenuation of peripheral vessels**
  b) **RVOT obstruction**: post-stenotic LPA dilatation in the presence of PS; RVH

1.8/ CORONARY ANGIOGRAPHY

PREPARATION

BASIC WORK-UP: CBC; ECG; electrolytes; creatinine-BUN; Clotting tests; target INR < 2.0

DIABETES: Discontinue metformin in the event of post-coronary angiography ARF

PREVENTION OF CONTRAST NEPHROPATHY: particularly if GFR < 60 mL/min or DM

a) **Hydration with normal saline**: **1 mL/kg/h x 3-12 h before and 6-24 h after angiography** (0.5 mL/kg/h if LVEF < 35% or NYHA III-IV)
b) **Minimize the volume of contrast: < 300 mL or < 4 mL/kg; avoid a contrast volume (mL) / GFR ratio > 3.7**; avoid multiple procedures < 48-72 h
c) **No benefit of N-acetyl-L-cysteine** (★ACT)
d) **Avoid nephrotoxic medications** (NSAIDs; ACE inhibitors; ARB)
e) **Preferred contrast agents: nonionic** (iso-osmolar or low osmolar)

IODINE ALLERGY: Prednisone 50 mg 12 h and 1 h before coronary angiography; Diphenhydramine 50 mg PO and Ranitidine 150 mg PO 1 h before coronary angiography

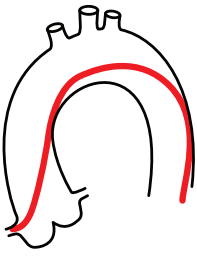
- **Urgent coronary angiography**: Methylprednisolone 125 mg IV + Diphenhydramine 50 mg

VASCULAR ACCESS

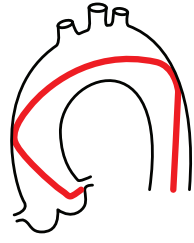
FEMORAL ACCESS: use the common femoral artery; puncture site 3 cm below the inguinal ligament (anterior superior iliac crest to superior pubic ramus) but proximal to the femoral bifurcation (bifurcation distal to the middle third of the femoral head); risk of retroperitoneal bleeding if the artery is punctured too high; risk of pseudoaneurysm if the artery is punctured too low

- **Withdrawal of the introducer**: ACT < 180 s

RADIAL ACCESS: Allen's test before (color returns to normal < 10 seconds); intraarterial Verapamil; Heparin IV (bolus of 2000 to 5000 units); 4-6 F catheters (1 F = 0.3 mm)

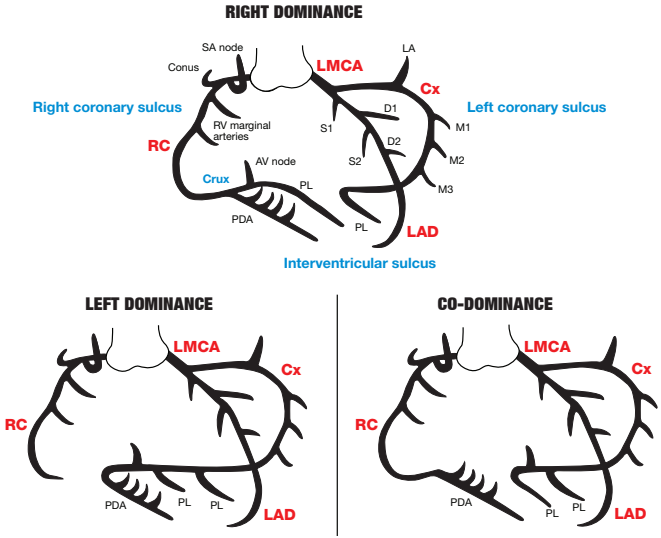


Right Judkins Catheter in the RCA



Left Judkins Catheter in the LCA

CORONARY ANATOMY



Source (with permission): *CathSource iPad application; Rocky Bilhartz, MD; http://ecgsource.com*

RIGHT DOMINANCE: 85% of patients; **PDA + ≥ 1 PL arise from the RCA**

- **Left dominance**: 7%; PDA and ≥ 1 PL arise from the circumflex; small RCA that does not perfuse the LV wall (ends before the crux cordis)
- **Co-dominance**: 7%; PDA arises from the RCA; all PL arise from the circumflex

VEIN GRAFT: adjacent to surgical clip

a) **Bypass graft of the RCA**: 5 cm above the sinotubular junction; right anterolateral aspect of the Ao
b) **Bypass graft of the LAD**: 7 cm above the sinotubular junction; anterior aspect of the Ao
c) **Bypass graft of the circumflex**: 9 cm above the sinotubular junction; left anterolateral aspect of the Ao

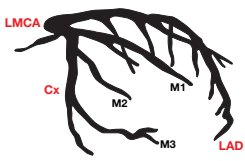
ANGIOGRAPHIC VIEWS

OBTAIN AT LEAST 2 PERPENDICULAR VIEWS for each vessel (to exclude eccentric lesions)

1) **RAO versus LAO versus PA versus lateral**
2) **Cephalic versus Caudal** (depending on the direction towards which the image intensifier above the patient is inclined); cephalic view → circumflex superior on the image; caudal view → LAD superior on the image

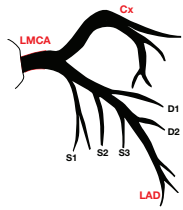
LEFT CORONARY

RAO 30° - CAUDAL 25°



Cx - Marginals - Distal LAD

RAO 10° - CEPHALIC 40°

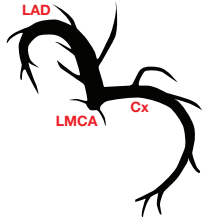


LAD - Septal - Diagonals

LAO 45° - CEPHALIC 25°

Mid and distal LAD - Diagonals - Distal dominant Cx

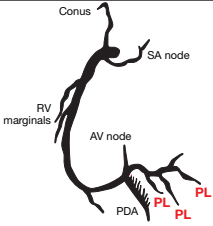
SPIDER: LAO 45° - CAUDAL 45°



LMCA - Proximal LAD - Proximal Cx

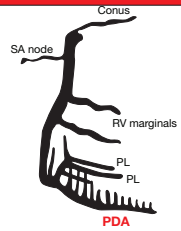
RIGHT CORONARY

LAO 30° - 0°



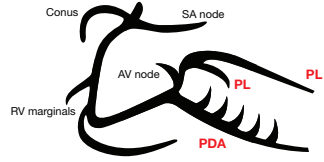
Proximal and mid RCA; PLs

RAO 30°- 0°



Mid RCA / Mid PDA

PA - 20° CEPHALIC



Distal RCA: PDA and PLs

Redrawn and expanded from (with permission): *Uptodate 2015; Zimetbaum PJ, Josephson ME. Conduction abnormalities after myocardial infarction; www.uptodate.com; Post TW (Ed), UpToDate, Waltham, MA, March 2015.*

CORONARY ARTERY STENOSIS

ANGIOGRAPHIC	HEMODYNAMIC	IVUS (INTRAVASCULAR ULTRASOUND)
≥ 70 % (LMCA: ≥ 50%)	FFR ≤ 0.80	• LMCA: Area < 6 mm² (6 to 7.5 mm² → determine FFR) • Other vessels: Area < 4 mm²

CHARACTERISTICS OF THE CORONARY LESION		
TYPE A: PCI WITH HIGH SUCCESS RATE (> 85%) AND LOW RISK	**TYPE B: PCI WITH MODERATE SUCCESS RATE (60-85%) AND MODERATE RISK**	**TYPE C: PCI WITH LOW SUCCESS RATE (< 60%) AND HIGH RISK**
• Short (10 mm) • Concentric • Only slightly calcified • Not totally occluded • Not ostial • Easily accessible • Not angulated (< 45°) • Regular contours • No branch lesion • Absence of thrombus	• Tubular (10-20 mm) • Eccentric • Moderately calcified • Total occlusion < 3 months • Ostial • Moderate tortuosities of proximal segment • Moderate angulation (45-90°) • Irregular contours • Bifurcation • Presence of thrombus	• Diffuse (> 20 mm) • Severe tortuosities of proximal segment • Extreme angulation (> 90°) • Bifurcation with impossibility to protect a major branch • Vein graft with friable lesions

a) **Length**: short (< 10 mm) - tubular (10-20 mm) - diffuse (> 20 mm)
b) **Ostial**: < 3 mm from the ostium; aorto-ostial stenosis often fibrocalcified
c) **Bifurcation**: Medina's X, Y, Z classification
   - **X**: 0 if absence of stenosis or 1 if stenosis in the main proximal segment
   - **Y:** 0 if absence of stenosis or 1 if stenosis in the main distal segment
   - **Z:** 0 if absence of stenosis or 1 if stenosis in the daughter branch
d) **Calcification**: confers rigidity and non-compliance to the dilatation
e) **Angulation**: > 45° moderate; > 90° severe; makes stent placement more difficult and associated with a risk of late stent fracture
f) **Thrombus**: risk of distal microembolism
g) **Eccentricity**: variable stenosis according to angiographic view
h) **Irregularities**: ulcer; intimal flap; aneurysm; saw tooth irregularities (multiple successive irregular stenoses)
i) **Tortuosity of the proximal segment**: moderate (2 proximal curves > 75°) or severe (3 proximal curves > 75°)
j) **Presence of collaterals**: Rentrop classification
k) **TIMI flow**

TIMI 0	Total occlusion
TIMI 1	Presence of a very faint anterograde flow beyond the stenosis; no opacification of the distal coronary bed
TIMI 2	Opacification of the entire distal coronary bed, but sluggish flow (compared to vessels with normal flow)
TIMI 3	Anterograde perfusion of all of the distal coronary bed; normal filling velocity

MICROVASCULAR EVALUATION: myocardial "blush" score

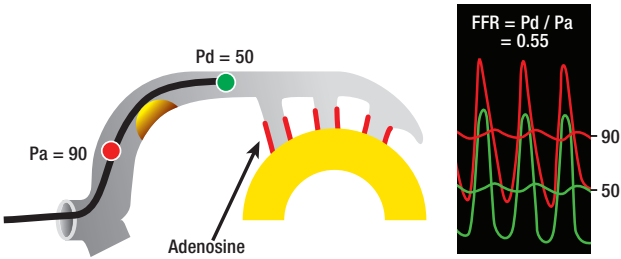
FRACTIONAL FLOW RESERVE (FFR)

INDICATION: **estimate the hemodynamic impact of an intermediate angiographic stenosis (50-70%)**

CALCULATION: Pressure distal to lesion (Pd) / Pressure proximal to lesion (Pa) ratio during maximum hyperemia (IV or intracoronary adenosine)

CORONARY BLOOD FLOW DEPENDS ON: **A)** DBP; **B)** Arteriolar resistance; **C)** Left intraventricular pressure; **D)** Degree of coronary stenosis

› **Abnormal FFR:** ≤ 0.80 (★FAME; ★FAME-2)

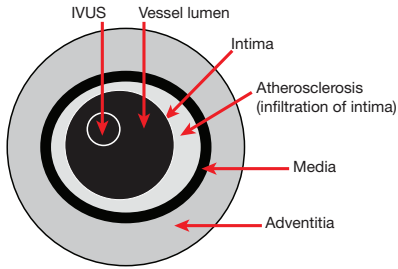


INTRAVASCULAR ULTRASOUND (IVUS)

Transverse ultrasound section of the lumen and arterial wall

EVALUATION: real dimensions of the lumen; abnormality of the arterial wall; degree of atherosclerotic infiltration; positive vascular remodeling (Glagov phenomenon)

INDICATION: A) Specify the severity of LMCA stenosis; **B)** Complex lesion (ostial; bifurcation; aneurysm; dissection); **C)** Bypass graft disease; **D)** Restenosis or intra-stent thrombosis; **E)** Guidance during PCI / evaluation of stent deployment



COMPLICATIONS

COMPLICATIONS: **Major complications < 1%;** Death; MI; Contrast nephropathy; Stroke; Local vascular complication (thrombosis; distal embolism; dissection; hematoma; pseudoaneurysm; AV fistula); Arrhythmia; Allergy; Air embolism; Coronary artery dissection; Atheroembolism

ANAPHYLAXIS: epinephrine 1:10,000 - **1 mL IV every minute (0.1 mg every minute)**

HEPARIN ANTIDOTE: Protamine (1 mg for every 100 units of heparin; if IV infusion of heparine → 25-50 mg of protamine IV slowly); risk of allergy if the patient is treated with NPH insulin

› www.medicines.org.uk/emc/medicine/10807/spc

RETROPERITONEAL HEMATOMA: secondary to puncture above the inguinal ligament; hypotension / abdominal pain / back pain; CBC - clotting tests; CT scan; reverse anticoagulation; transfusion PRN; medical treatment in the majority of cases (or covered stent)

PSEUDOANEURYSM: pulsatile mass with systolic murmur; ultrasound diagnosis; good prognosis if diameter < 2 cm

› **Noninvasive percutaneous treatment**: ultrasound-guided compression or local injection of thrombin; follow-up US at 1 month
› **Surgery:** large or rapidly progressive pseudoaneurysm or infected or failure of noninvasive treatment

AV FISTULA: secondary to puncture below the femoral bifurcation; thrill or continuous murmur; surgical treatment in the majority of cases (risk of progression)

RADIAL ACCESS COMPLICATIONS: Hematoma; Arterial dissection or occlusion; Loss of radial pulse; Compartment syndrome; Spasm

POST-CORONARY ANGIOGRAPHY ARF

› **Contrast nephropathy**: **Early and reversible ARF; Improvement by day 3 to 5**

RISK OF CONTRAST NEPHROTOXICITY POST–PCI		
Hypotension	5 points	**≤ 5 POINTS** • Contrast nephropathy: 7.5% • Dialysis: 0.04% **6-10 POINTS** • Contrast nephropathy: 14% • Dialysis: 0.1% **11-16 POINTS** • Contrast nephropathy: 26% • Dialysis: 1% **> 16 POINTS** • Contrast nephropathy: 57% • Dialysis: 13%
IABP	5 points	
Heart failure	5 points	
> 75 years	4 points	
Anemia	3 points	
Diabetes	3 points	
Each 100 mL of contrast	1 point	
Creatinine > 130 mmol/L or GFR 40-60 mL/m² GFR 20-40 mL/m² GFR < 20 mL/m²	4 points or 2 points 4 points 6 points	

Mehran R, Aymong ED, Nikolsky E et al. JACC 2004; 44; 1393-1399.

› **Atheroembolism: subacute ARF** (several days to several weeks); **eosinophilia / eosinophiluria; slightly active urinary sediment; hypocomplementemia; other micro atheroembolic lesions** (toes; livedo reticularis; petechiae; splinter hemorrhage; mesenteric or pancreatic ischemia; retinal Hollenhorst plaques); slight improvement of renal function

1.9/ HEMODYNAMIC ASSESSMENT

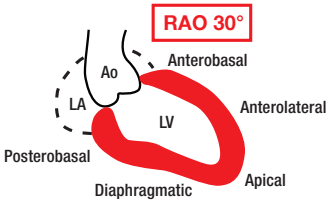
INDICATIONS: More refined assessment of heart disease when noninvasive evaluation is insufficient (heart failure; valvular heart disease; PHT; complicated myocardial infarction; congenital heart disease; intracardiac shunt; pericardial disease; cardiomyopathy; biopsy)

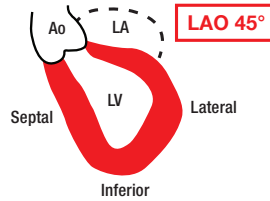
COMPLICATIONS: < 1%; death; MI; stroke; arrhythmia; access site complication; allergy to contrast agent; cardiac tamponade / perforation; RBBB during catheterization of RV and LBBB during catheterization of LV; pulmonary infarction; PA perforation

RIGHT CARDIAC CATHETERIZATION: RA - RV - PA - pulmonary capillary wedge pressures; cardiac output; search for a shunt; calculation of pulmonary vascular resistance

LEFT CARDIAC CATHETERIZATION: LA pressure (transseptal or estimated by wedge pressure) - LV - Ao pressures; coronary angiography; left ventriculography and aortography; calculation of systemic vascular resistance; evaluation of valvular heart disease

- **Transseptal**: verification of the correct position (LA) by atrial pressure curve - oxygen saturation - contrast injection
- **Left ventriculography**: RAO 30° ± LAO 45° (30-40 mL of contrast)





HEMODYNAMIC DATA

MEASUREMENTS: **at the end of expiration**

	MEAN	NORMAL
Cardiac output (L/min)	5	4 - 6
Cardiac Index (L/min/m²)	3.5	2.5 - 4.5
Aorta pressure (mmHg)		
Systole	130	90-140
End-diastole	70	60-90
Mean	85	70-105
Mean BP = 1/3 x SBP + 2/3 X DBP		
LV PRESSURE (mmHg)		
Systole	130	90-140
End-diastole	8	5-12
LA pressure (v > a) (mmHg)		
Max	12	6-21
Mean	8	2-12
PCWP (mmHg)		
Mean	9	4-12
PAP (mmHg)		
Systole	25	15-30
End-diastole	9	4-12
Mean	15	9-19
Mean PAP = 1/3 x sPAP + 2/3 x dPAP		

	MEAN	NORMAL
RV pressure (mmHg)		
Systole	25	15-30
End-diastole	4	1-7
RA (a > v) (mmHg)		
Max	6	2-7
Mean	3	1-5
Resistance (dyn x s / cm^5)		
Systemic vascular resistance	1100	700-1600
Pulmonary vascular resistance	70	20-130

- **Δ P = Q x R**
- **Systemic vascular resistance (WU)** = Mean arterial pressure - Mean RA pressure / Systemic output
- **Pulmonary vascular resistance (WU)** = Mean PAP - Mean wedge pressure / Pulmonary output
- **Conversion**: 1 WU = 80 dyn x s / cm^5

CARDIAC OUTPUT

FICK: gold standard method

- **Systemic cardiac output (L/min)** = O_2 consumption (mL/min) / 1.36 x Hb (g/L) x (Aortic SaO_2 - Mixed venous SaO_2)
- **Pulmonary cardiac output (L/min)** = O_2 consumption (mL/min) / 1.36 x Hb (g/L) x (PV SaO_2 - PA SaO_2)

- **Estimation of O_2 consumption**: 125 ml/m² in young subjects; 110 mL/m² in elderly subjects
- **SaO_2:** expressed as a decimal (70% = 0.70)
- **Mixed venous SaO_2**: = 3/4 x SVC SaO_2 + 1/4 x IVC SaO_2

› **Caveats**: **A)** Estimation of VO_2 (instead of measurement of VO_2 by face tent); **B)** High output (attenuated arteriovenous O_2 difference)

THERMODILUTION: injection of a bolus of NaCl into the vena cava; detection of a change of temperature as a function of time in a distal port (pulmonary artery); **cardiac output is inversely proportional to the area under the curve**

› **Caveats**: **A)** Significant TR (underestimates cardiac output); **B)** Low output (< 2.5 L/m) in which case cardiac output is overestimated; **C)** Intracardiac shunt (cardiac output overestimated if L⟶R shunt)

ANGIOGRAPHIC METHOD

- **Cardiac output** = (LV end-diastolic volume - LV end-systolic volume) x HR

› **Caveats**: **A)** Evaluation of cardiac output in a single cardiac axis; **B)** Less reliable in the presence of MR, AR or AF

HEMODYNAMIC CURVES

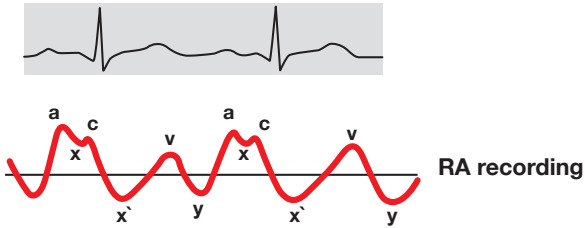
Use the ECG to identify waves on the curves

A) Polyphasic curves: atrial recording; pulmonary capillary wedge pressure recording

B) Monophasic curve

- **Ventricular recording**: End-diastolic pressure > Early diastolic pressure
- **Arterial recording**: Early diastolic pressure > End-diastolic pressure

ATRIAL RECORDING



A WAVE: atrial kick; **follows the P wave on the ECG**

- **Normally**: a > v in RA; v > a in LA
- ↗ **a wave**: MS (or TS); ↘ ventricular compliance (LVH or RVH; LVOT or RVOT obstruction)
- **Canon a wave**: AV dissociation (AV block; ventricular pacemaker; VT; PVC; PAC)
- **Absent a wave**: AF or atrial flutter; severe atrial disease (Ebstein; rheumatic MS; cardiac amyloidosis)

X DESCENT: atrial relaxation; **after S1**

- ↗ **x descent**: Tamponade; Constriction (W-M pattern)

C WAVE: protrusion of the AV valve into the atrium during isovolumic contraction of the ventricle

X' DESCENT: atrial relaxation + descent of AV valve during systolic ejection

V WAVE: passive atrial filling during ventricular systole in the presence of a closed AV valve; **at the end of the T wave on the ECG**

- ↗ **v wave**: MR (or TR); VSD (or ASD on RA recording); rheumatic MS (↘ LA compliance); Heart failure

Y DESCENT: emptying of the atrium following opening of the AV valve (rapid ventricular filling); **after S2**

- ↗ **y descent**: Constriction; RCM; MR (or TR)
- ↘ **y descent**: Tamponade; MS (or TS)

PCWP: pulmonary capillary wedge pressure; similar curve to LA but delayed by 40-120 ms (pressure transmission delay) and slightly attenuated

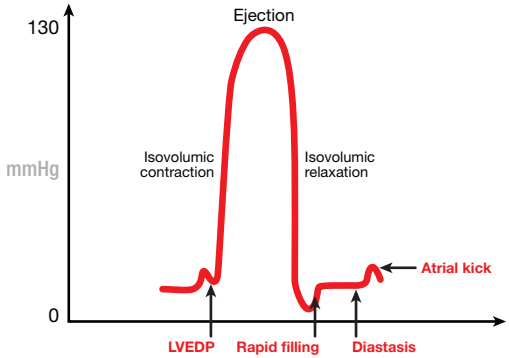
- **Adequate wedge pressure**: oximetric confirmation (SaO_2 > 95 %); injection of contrast; respiratory variation of the curve
- **Inequality between wedge pressure and LA pressure**: PV obstruction; ↗ Pleural pressure; Catheter in non-dependent pulmonary zone (target West zone 3)
- **dPAP > Wedge**: Pulmonary disease; Pulmonary embolism; significant PHT

VENTRICULAR RECORDING

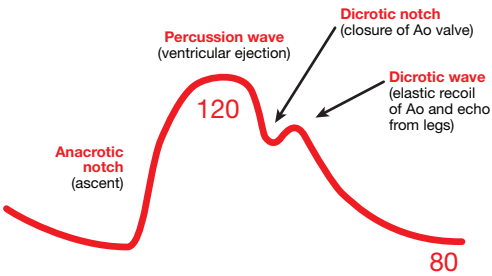
SYSTOLE: **A)** Isovolumic contraction; **B)** Ejection; **C)** Reduced ejection then start of relaxation

DIASTOLE: A) Isovolumic relaxation; **B)** Rapid filling; **C)** Slow filling (diastasis); **D)** Atrial kick

- **End-diastolic pressure**: after atrial kick at point c (simultaneous with QRS)



ARTERIAL RECORDING



PULSE PRESSURE: reflects the stroke volume and compliance of the arterial system

- ↗ **pulse pressure: > 50 % of SBP** (or > 40 mmHg); HTN; Age; AR; patent ductus arteriosus; Ruptured aneurysm of the sinus of Valsalva; Fever; Anemia; Hyperthyroidism; Pregnancy; AV fistula; Paget's disease +
- ↘ **pulse pressure**: **< 25% of SBP**; Tamponade; Heart failure; Cardiogenic shock; Aortic stenosis +

CAROTID PULSE: similar to central aortic pulsation

CORRIGAN'S PULSE (BOUNDING)	 Abrupt systolic ascent, followed by rapid collapse; increased pulse pressure	**DDx**: AR; patent ductus arteriosus; truncus arteriosus; fever; anemia; hyperthyroidism; pregnancy; exercise; AV fistula; Paget's disease; Beriberi; bradycardia in an elderly patient with non-compliant aorta
PULSUS PARVUS ET TARDUS (ANACROTIC)		• **AS** • **Tardus**: slow ascent • **Parvus:** decreased amplitude • ± Thrill
PULSUS BISFERIENS (BIFID)	 2 peaks during systole (percussion wave then tidal wave)	• **DDx**: AR; HCM; patent ductus arteriosus • **Tidal wave:** echo from leg vessels • **HCM: spike and dome** (rapid initial ascent then dynamic LVOT obstruction)
DICROTIC PULSE	 1 peak in systole and 1 peak in diastole	**DDx**: IABP; severe heart failure; tamponade; hypovolemia; sepsis
PULSUS PARADOXUS	 **> 10 mmHg reduction** of systolic blood pressure on inspiration	**DDx**: Tamponade; constriction - effusion; RCM; COPD; Asthma; Pulmonary embolism; Pneumothorax; Hypovolemia; Obesity; Pregnancy • **Reversed pulsus paradoxus:** HCM
PULSUS ALTERNANS		**DDx**: Severe heart failure; bigeminy; tamponade; severe AR; tachypnea

AORTIC STENOSIS

TRANSVALVULAR GRADIENT: measurement of blood pressures in proximal Ao and LV

- **Mean gradient**: integral of the transvalvular gradient during systole
- **Peak-to-peak gradient**: not physiological as peaks not simultaneous
- **Pressure in femoral artery**: **underestimation** of transvalvular gradient (due to peripheral amplification of SBP)

FIXED OBSTRUCTION: **pulsus parvus et tardus** on aortic recording

CARABELLO'S SIGN: **> 10 mmHg** increase in SBP following withdrawal of the catheter from the LV towards the aorta (obstructive catheter in critical aortic stenosis)

HAKKI FORMULA: Aortic valve area = CO (L/min) / √ mean gradient (or peak-to-peak gradient)

GORLIN FORMULA: Aortic valve area = Stroke volume (mL/beat) / (44.3 x Systolic ejection period (s / beat) x √ Mean gradient mmHg)

CAVEATS: A) Concomitant AR: calculate cardiac output (or stroke volume) by the angiographic method; **B)** Aortic stenosis in the presence of low cardiac output (dobutamine challenge)

MITRAL STENOSIS

TRANSVALVULAR GRADIENT: transseptal measurement of LA and LV pressures

- **LA pressure estimated by PCWP**: **overestimates the transvalvular gradient** (delayed transmission of pressure waves and attenuation of y descent)

GORLIN FORMULA: Mitral valve area = Stroke volume (mL/beat) / (37.7 x Diastolic filling period (s / beat) x √ mean gradient mmHg)

CAVEAT: Concomitant MR: calculate stroke volume by angiographic method

VALVULAR REGURGITATION

REGURGITANT VOLUME = Angiographic stroke volume (end-diastolic volume - end-systolic volume) - Net anterograde stroke volume (Fick or Thermodilution)

REGURGITANT FRACTION = Regurgitant volume / Angiographic stroke volume

SEMIQUANTITATIVE ANGIOGRAPHIC EVALUATION (ventriculography or aortography)

GRADE	Regurgitant fraction	Opacification of the proximal chamber
1	< 20 %	• Slight opacification • Rapid elimination of contrast at each beat
2	21-40 %	• Moderate opacification • Density less than that of the proximal chamber • Rapid elimination of contrast with subsequent beats
3	41-60 %	• Intense opacification • Similar density to that of the proximal chamber in 4-5 beats
4	> 60 %	• Intense and rapid opacification • Density greater than that of the proximal chamber in ≤ 3 beats • ± PV reflux in the presence of MR

INTRACARDIAC SHUNT

Level of L→R shunt	Increased SaO_2 (step-up)	Example
Screening	PA SaO_2 - SVC SaO_2 ≥ 8%	Shunt at any level between the SVC and the PA
Atrial	RA SaO_2 - mixed venous SaO_2 ≥ 7%	ASD; Partial anomalous pulmonary venous connection; Ruptured aneurysm of the sinus of Valsalva; VSD + TR; Coronary fistula to RA
Ventricular	RV SaO_2 - RA SaO_2 ≥ 5%	VSD; Patent ductus arteriosus + PR; Primum ASD; Coronary fistula to RV
Pulmonary artery	PA SaO_2 - RV SaO_2 ≥ 5%	Patent ductus arteriosus; Aortopulmonary window; Palliative shunt (Pots; Waterston)

QP / QS: Pulmonary blood flow / Total systemic blood flow

QP / QS = Ao SaO_2 - mixed venous SaO_2 / PV SaO_2 - PA SaO_2

MIXED VENOUS SaO_2 = 3/4 x SVC SaO_2 + 1/4 x IVC SaO_2

PV SaO_2: ≈ Ao saturation in the absence of R→L shunt

Qp / Qs < 1.5	Qp / Qs 1.5 - 2	Qp / Qs > 2
Small L→R shunt	Moderate L→R shunt	Large L→R shunt

OXIMETRIC RUN: SVC (2 x); IVC (2 x); RA (3 x); RV (3 x); main PA; RPA; LPA; LV; Ao; ± PV and ± LA

SCREENING OF R→L SHUNT: Ao SaO_2 < 95% despite FiO2 = 100%

1.10/ NUCLEAR MEDICINE

SPECT MYOCARDIAL PERFUSION IMAGING

SPECT: Single-Photon Emission Computed Tomography

PRINCIPLE: Injection of a radioisotope (at rest then on exercise) → extraction by viable perfused myocytes → **emission of photons proportional to myocyte perfusion**

THREE STANDARD PERPENDICULAR PLANES: **A)** Short axis (apex to base); **B)** Vertical long axis (septum to lateral wall); **C)** Horizontal long axis (inferior wall to anterior wall)

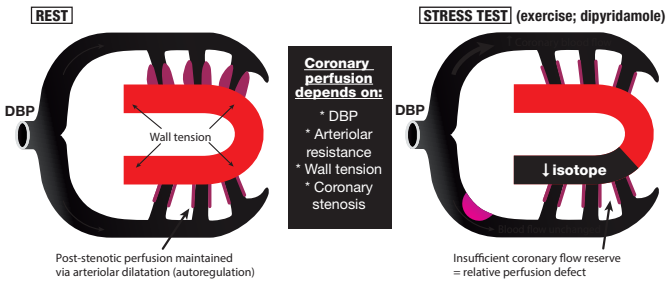
ARTIFACTS / FALSE-POSITIVES: **A)** Movement during acquisition; **B)** Extraction of radioisotope by visceral organs; **C)** LBBB (use pharmacological stress); **D)** Septal HCM (relative perfusion deficit in lateral wall compared to hypertrophied septum); **E)** Dilated cardiomyopathy or HCM (zones of fibrosis; endothelial dysfunction); **F)** Attenuation

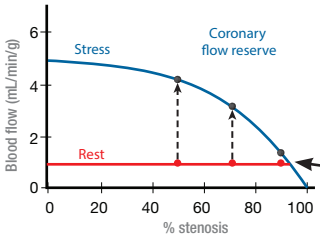
- **Attenuation by interposed structure**: **A)** Breasts → anterior / anterolateral attenuation; **B)** Diaphragm → inferobasal attenuation (improvement when patient upright)
  - **Rule out attenuation: A)** Raw cine mode (look for interposed structure); **B)** Ventricular function (real perfusion deficit unlikely if normal wall motion on stress test)
- **Normal variants**: Membranous basal septum (less perfused); Apical thinning; Lateral wall appears to be better perfused than the septum (closer to the camera)

	201–Thallium	99m Technetium
Molecule	Cation; similar properties to K+	• Fat-soluble cationic compound • Sestamibi and Tetrofosmin
Photon energy	80 keV	140 keV
Half-life	73 h	6 h
First-pass myocardial extraction	• 85 % • Perfusion-dependent • Via Na-K-ATPase pump	• 60 % • Perfusion-dependent • Passive myocardial extraction (radioisotope trapped in mitochondria)
Myocardial redistribution	• Imaging 3-4 h or 24 h post-injection • Clearance of radioisotope is slower in ischemic myocardium ("differential washout")	Minimal (2 injections are therefore necessary: stress test and at rest)
Protocol	1. **Detection of ischemia**: Injection on stress test with imaging #1; imaging #2 post-redistribution 2. **Viability study**: Injection at rest with imaging #1; imaging #2 post redistribution (re-injection at this time to improve sensitivity)	1. **Same day**: injection at rest (8-10 mCi) with imaging #1; injection on stress test with imaging #2 (22-30 mCi) 2. **2 days**: injection at rest (20-30 mCi) with imaging #1; injection on stress test (20-30 mCi) with imaging #2 3. **Combined with Thallium**: Injection of Thallium at rest with imaging #1; imaging #2 4h pre-Technetium (redistribution; viability study); injection of Technetium on stress test with imaging #3 (to detect ischemia)

DIPYRIDAMOLE PHARMACOLOGICAL STRESS TEST: ↗ intracellular adenosine → stimulation of smooth muscle cell adenosine A2a receptors → ↗ cAMP → coronary arteriolar vasodilatation → ↗ coronary blood flow

- **Dose**: 142 µg/kg/min x 4 min (then inject isotope 3 min later)
- **Adverse effects**: ↘ SBP and ↘ DBP (8-10 mmHg); reflex tachycardia **(↗ 10-20 bpm); minimal increase of double product (i.e. slightly ↗ 0_2 demand)**; flushing; retrosternal chest pain; asthma; blocks; real ischemia (in 10% of cases; coronary steal in ischemic collateral vessels)
- **Antidote**: aminophylline 1-2 mg/kg





HIGH RISK CRITERIA

- **Negative test:** 1-year risk of death or myocardial infarction < 1% (exercise) or < 2% (dipyridamole)
- **Resting LVEF**: < 35 %
- **Extensive perfusion abnormality during stress**: ≥ 10% of the myocardium or involving ≥ 2 vascular territories
- **Pulmonary uptake of ^{201}Tl (during stress)**: marker of severe CAD (↗ wedge pressure and ↘ LVEF during stress)
- **Transient LV dilatation (during stress)**: ↗ ventricular chamber size; marker of severe CAD (↘ LVEF during stress and/or diffuse subendocardial ischemia)

VENTRICULAR FUNCTION: ECG-gated imaging → mean of hundreds of beats to obtain one cardiac cycle

RADIONUCLIDE VENTRICULOGRAPHY (RVG)

Evaluation of LVEF and RVEF

EQUILIBRIUM (MUGA): ECG gating; 99m Technetium-labeled RBC; mean of 1000 cycles; 3 standard views (anterior; LAO with optimal separation of RV and LV; lateral); evaluation of chamber dimension - regional wall motion - systolic function

- **Systolic function:** estimated on biplane mode by counting photon emissions in the ventricle (diastole - systole / diastole)
  - **Systolic volume**: the count is proportional to ventricular volume (which can be estimated from a blood sample of a given volume and a given photon emission); measurement not influenced by ventricular geometry
- **Diastolic function**: curve of ventricular volume as a function of time

FIRST-PASS: rapid bolus of Technetium 99m-DTPA → RA - RV → Lungs → LA - LV; can distinguish the activity of right and left (**better evaluation of the RV and shunt**); RAO view

POSITRON EMISSION TOMOGRAPHY

Quantitative evaluation of myocardial perfusion

ADVANTAGES VERSUS SPECT: better spatial resolution; better correction of attenuation; evaluates **absolute quantitative regional perfusion (mL/g/min) (unlike SPECT which evaluates relative regional perfusion);** better evaluation of balanced ischemia or microvascular disease

- **Disadvantages**: requires a cyclotron; short half-life (pharmacological stress test only)
- **^{82}Rubidium**: cation with similar properties to those of the potassium and thallium; transport via Na-KATPase pump; half-life 75 s; perfusion-dependent myocardial extraction
- **[^{13}N]ammonia**: passive diffusion or transport via Na-K-ATPase pump; half-life 10 min; perfusion-dependent myocardial extraction

VIABILITY STUDY: quantitative evaluation of myocardial metabolism (2-[^{18}F]FDG); **glucose extraction maintained in ischemic myocardium** (anaerobic glycolysis); **"mismatch" between myocardial perfusion and glucose metabolism in ischemic but viable (hibernating) myocardium** +

MULTIMODAL EVALUATION OF VIABILITY			
DOBUTAMINE ECHOCARDIOGRAPHY	**THALLIUM**	**CARDIAC PET**	**GADOLINIUM ENHANCED CARDIAC MRI**
Hibernating myocardium: Biphasic response	**Hibernating myocardium:** Redistribution	**Hibernating myocardium:** Perfusion-metabolism discordance	**Late gadolinium enhancement** = scar (absence of viability)
Resting Baseline RWMA **Dobutamine 5 µg/kg/min** Improvement **Dobutamine 20 µg/kg/min** Deterioration	**Resting** Relative perfusion deficit **Redistribution** Differential washout	**Resting** Relative perfusion deficit **FDG metabolism** Glucose extraction maintained	**Resting** Late gadolinium enhancement = scar

1.11/ CARDIAC MAGNETIC RESONANCE IMAGING (CARDIAC MRI)

PHYSICAL PRINCIPLE: detects electromagnetic signals of nuclei of hydrogen atoms following application of a specific sequence of magnetic fields

PRECAUTIONS

CONTRAINDICATIONS: **ferromagnetic material** (stents and valve prosthese safe); **www.mrisafety.com**

- **Pacemaker and defibrillator (before new compatible generation)**: contraindication to MRI; risk of arrhythmia; displacement of the device; inhibition; inappropriate shock; lead injury; battery depletion...

GADOLINIUM: risk of nephrogenic systemic fibrosis if **CrCl < 30 mL/min/1.73 m²**

TISSUE CHARACTERIZATION

T1	**Fat content:** ARVD; myocardial mass	
T2	**Myocardial water content:** acute myocarditis; acute myocardial infarction (high-risk zone); graft rejection	
T2*	**T2* < 20 msec:** (associated with LV dysfunction) compatible with iron overloard cardiomyopathy (repeated transfusions; hemochromatosis)	
T1 Gadolinium-enhanced	Visualization of intravascular (blood) and extravascular water (myocardium) • **First pass**: myocardial perfusion • **Early gadolinium enhancement (EGE):** sign of inflammation (myocarditis; acute myocardial infarction) • **Late gadolinium enhancement (LGE):** 15 minutes post-redistribution; sign of fibrosis / myocardial necrosis	
Ischemic heart disease	**LGE**: **subendocardial or transmural scar**	
Nonischemic cardiomyopathy	**LGE: non-subendocardial scar**	
HCM	**LGE:** scars in hypertrophied regions or in IV septum or close to the insertion of the RV	
Amyloidosis	• Rapid accumulation of contrast in the myocardium (rapid first-pass washout from blood) • **LGE**: circumferential subendo-cardial enhancement; transmural patchy enhancement • Late atrial enhancement	
Sarcoidosis Myocarditis	• **LGE**: intramural or subepicardial or epicardial scar, sparing the endocardium • **Sarcoidosis**: anteroseptal and inferolateral walls often affected	

INDICATIONS

CARDIOMYOPATHY / HEART FAILURE / MYOCARDITIS: dimensions; systolic and diastolic functions; segmental wall motion; measurement of deformation (strain); tissue characterization (sarcoidosis; myocarditis; amyloidosis; hemochromatosis); viability - scars (LGE); HCM; ARVD; LV noncompaction; Chagas…

CORONARY DISEASE: scar - viability (LGE); congenital anomaly of coronary arteries; coronary fistula; segmental wall motion (at rest and with dobutamine); first-pass gadolinium perfusion study (at rest and with dipyridamole); acute myocardial infarction (T2)

VALVULAR HEART DISEASE: stenosis (phase contrast is used to measure transvalvular velocities); regurgitation (volumetric method comparing RV and LV stroke volumes; phase contrast is used to measure anterograde and retrograde transvalvular velocities to calculate the regurgitant volume); perivalvular mass (fibroelastoma; vegetation; thrombus); complication of endocarditis; prosthetic valve dysfunction

CARDIAC MASSES: intracardiac thrombus (**non-vascularized**; absence of gadolinium enhancement); primary and secondary tumors (metastases)

PERICARDIAL DISEASE: constriction (paradoxical movement of the interventricular septum; ventricular interdependence; IVC distension); congenital absence of pericardium

CONGENITAL HEART DISEASE: anatomical assessment; structure - dimensions - function of chambers; conduits; shunts; Ao and PA

THORACIC AORTA: aneurysm; ulcer; dissection; CoA; aortitis; post-surgery; intramural thrombus

1.12/ CARDIAC CT

UNENHANCED CORONARY CALCIUM SCAN

This technique estimates the global coronary atherosclerotic burden; **very high sensitivity but low specificity for significant coronary stenosis**; independent predictor of coronary events (score of 0 associated with excellent prognosis)

INDICATIONS: **asymptomatic patient with intermediate risk of cardiac events (10-20% at 10 years)** +

- **Agatston score**: score > 300 confers a 10-year risk of myocardial infarction or cardiovascular mortality of 28% (score of 100-399 increases the risk x 4 versus score < 100; score > 400 increases the risk x 6)

CARDIAC CT ANGIOGRAPHY (CCTA)

STRUCTURES EVALUATED: heart chambers; ventricular function (R and L); coronary arteries; bypass grafts; aortic and pulmonary arteries; pericardium; other adjacent structures; congenital heart disease; congenital coronary artery anomalies; endocarditis; ARVD; prosthetic valve; cardiac mass / thrombus; pulmonary veins

CORONARY CT ANGIOGRAPHY: good spatial resolution (vessels > 1.5 mm); **excellent sensitivity for significant coronary stenosis (very high negative predictive value for CAD); stenosis identified is not necessarily hemodynamically significant** and is not necessarily associated with ischemia (FFR-CT under development); decreased specificity in the presence of significant calcifications (Agatston score > 400) or obesity or HR > 65 bpm or AF or stent; independent predictor of coronary events (negative CCTA associated with excellent prognosis); can be used to evaluate patency of coronary bypass grafts; no difference on clinical outcome between CCTA vs. Functional testing in patients with suspected CAD (★ PROMISE) +

› **Indication: A)** Patient with no history of CAD presenting with retrosternal chest pain and intermediate pretest probability (especially when other noninvasive tests are inconclusive); **B)** Patient with low to moderate risk ACS (★ROMICAT-II); **C)** Rule out congenital anomaly of coronary arteries; **D)** Potential value for pre-op assessment before cardiac surgery when bypass graft is not planned (rule out significant CAD)

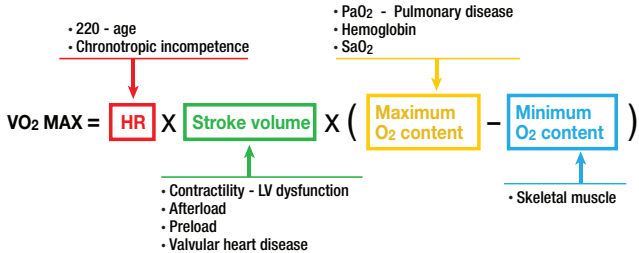
1.13/ CARDIOPULMONARY EXERCISE TESTING

Global evaluation of the oxygen transport system

INDICATIONS: **A)** Pre-transplantation assessment; **B)** Distinguish cardiac dyspnea from pulmonary dyspnea

PROTOCOL: Naughton; ↗ 1 MET every 2 min

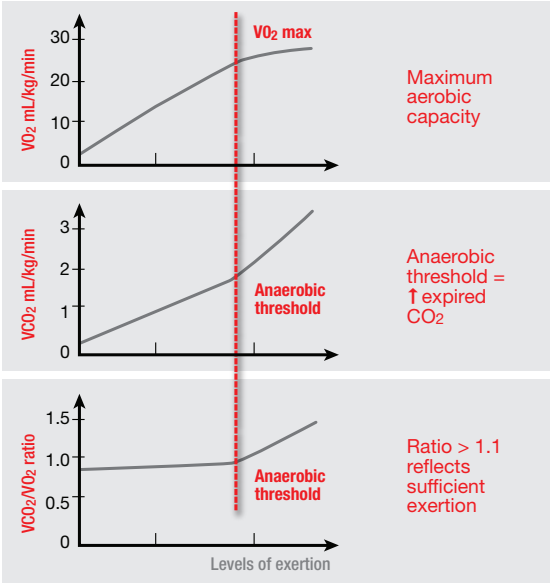
FICK EQUATION



PARAMETERS MEASURED: VO_2 (O_2 consumption); VCO_2 (CO_2 production); VE (minute ventilation); HR; BP; RR; SaO_2; PFTs; exercise ECG

- › **Ventilatory anaerobic threshold (VAT):** value of VO_2 when the slope of VE (or the slope of VCO_2) increases disproportionately to the slope of VO_2 (↗ CO_2 to be expired secondary to anaerobic glycolysis with formation of lactate); often at 50-60% of VO_2max (point at which dyspnea is experienced); activities of daily living situated below the VAT
- › **Respiratory exchange ratio (VCO_2/VO_2)**: **ratio > 1.05 means that the patient has achieved adequate exertion** +
- › **VE/VCO_2 slope**: **slope > 35 associated with poor prognosis**; reflects hyperventilation secondary to V/Q abnormalities with ↗ dead space +
- › **Borg scale**: quantification of the exertion perceived by the patient; > 18 / 20 = maximum exertion; > 15-16 / 20 = anaerobic threshold reached

	VO_2 MAX	ANAEROBIC THRESHOLD	MAXIMUM CARDIAC INDEX
Heart failure with good prognosis	> 18 mL O_2/kg/min	> 14 mL O_2/kg/min	> 8 L/min/m²
High-risk heart failure (consider transplantation)	< 10 mL O_2/kg/min (anaerobic threshold reached)	< 8 mL O_2 /kg/min	< 4 L/min/m²
Gray zone	VE/VCO_2 slope > 35 associated with poor prognosis		



1.14/ EXPOSURE TO RADIATION DURING CARDIAC EXAMINATIONS

CXR (PA - lateral)	0.1 mSv
Diagnostic coronary angiography	7 mSv
PCI (or RF ablation)	15 mSv
Coronary CT angiography	5 mSv
Coronary calcium scan	3 mSv
MibiP	9.4 mSv
Thallium (stress - redistribution)	41 mSv
FDG PET	8 mSv
V/Q scintigraphy	2.2 mSv
CT pulmonary angiography	15 mSv
Radionuclide ventriculography (equilibrium)	7.8 mSv

Coronary artery disease (CAD) & Myocardial infarction

02

2.1/ Stable angina 72
2.2/ Biomarkers 80
2.3/ Myocardial infarction: Definition 81
2.4/ Unstable angina & NSTEMI 83
2.5/ STEMI 88
2.6/ Acute coronary syndrome: Adjuvant treatments 95
2.7/ Complications of myocardial infarction 98
2.8/ Revascularization - PCI 103
2.9/ Revascularization - Coronary artery bypass graft 106
2.10/ Prinzmetal angina (vasospastic angina) 108
2.11/ Cardiac syndrome X 108

2.1/ STABLE ANGINA

O_2 DEMAND
- HR
- Wall stress (preload; afterload)
- Contractility

O_2 SUPPLY
- Coronary perfusion pressure (DBP – LVEDP)
- Patent coronary arteries
- Blood O_2 content

ANGINA: Clinical diagnosis +

Constrictive retrosternal chest pain	On exertion (or emotions)	Relieved by rest (5–10 min) or nitrates
Typical chest pain = 3	Atypical chest pain = 2	Nonanginal chest pain = 1

CLINICAL HISTORY: Nature; Site; Radiation; Tempo; Duration; Modifiers; Associated symptoms (cardiovascular; respiratory; gastrointestinal)

SEVERITY OF ANGINA

CCS 1/4	Ordinary activity does not cause angina	**≥ 7 METs** • Angina occurs with strenuous or rapid or prolonged exertion only
CCS 2/4	Slight limitation of ordinary activity	**5–7 METs** • ≥ 2 flights of stairs • Walking ≥ 3 blocks on the level (or walking uphill) • Exertion after meals or in cold weather
CCS 3/4	Marked limitation of ordinary activity	**2–5 METs** • ≤ 1 flight of stairs • Walking one or two blocks on the level
CCS 4/4	Inability to carry out any physical activity without discomfort or angina at rest	**< 2 METs** • Any activity • Walking several steps

ANGINA EQUIVALENT: Dyspnea; Tiredness

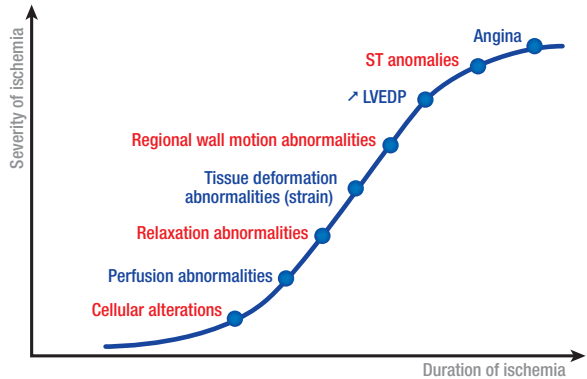
CHARACTERISTICS NOT IN FAVOR OF CARDIAC CHEST PAIN: Pleuritic; Abdominal; Localized; Reproduced on palpation; Reproduced on movement; Duration < several seconds or > several hours

DDX: Aortic dissection; Aortic stenosis; HCM; Secondary ischemia (anemia; hyperthyroidism; arrhythmia); Cocaine; Pericarditis; Myocarditis; Takotsubo; Cardiac syndrome X (Microvascular); Pulmonary embolism; Pneumothorax; Pneumonia; PHT (RV ischemia); Pleurisy; Ruptured esophagus (Boerhaave); Pancreatitis; Cholecystitis; Cholelithiasis; Peptic ulcer (perforated); GERD; Esophageal spasm; Musculoskeletal; Costochondritis; Neck pain; Shoulder tendinitis; Shingles; Psychiatric

TWO OBJECTIVES

a) Confirm the diagnosis of CAD
b) Establish the prognosis of the patient's CAD

ISCHEMIC CASCADE



PRETEST PROBABILITY OF SIGNIFICANT CAD on coronary angiography in a patient with retrosternal chest pain

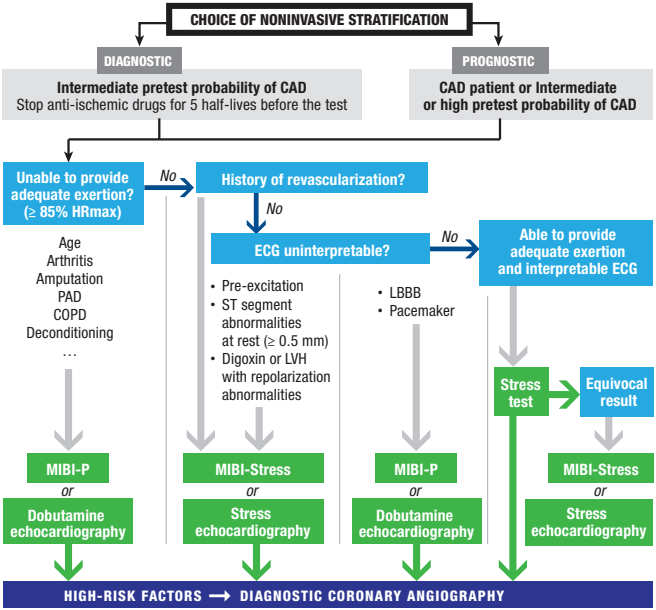
AGE	NONANGINAL CHEST PAIN (≤ 1 CHARACTERISTIC)		ATYPICAL CHEST PAIN (2 CHARACTERISTICS)		TYPICAL CHEST PAIN (3 CHARACTERISTICS)	
	M	F	M	F	M	F
30–39	4 %	2 %	34 %	12 %	76 %	26 %
40–49	13 %	3 %	51 %	22 %	87 %	55 %
50–59	20 %	7 %	65 %	31 %	93 %	73 %
60–69	27 %	14 %	72 %	51 %	94 %	86 %

Diamond GA, Forrester JS. N Engl J Med 1979; 300:1350

BAYES' THEOREM: the predictive value of a test depends on its sensitivity, specificity, and the pretest probability of the disease

› The diagnostic value of the test (when it is used to confirm the diagnosis of CAD) is maximal in patients with an **intermediate pretest probability of CAD (10-90%)**

CHOICE OF NONINVASIVE STRATIFICATION MODALITY

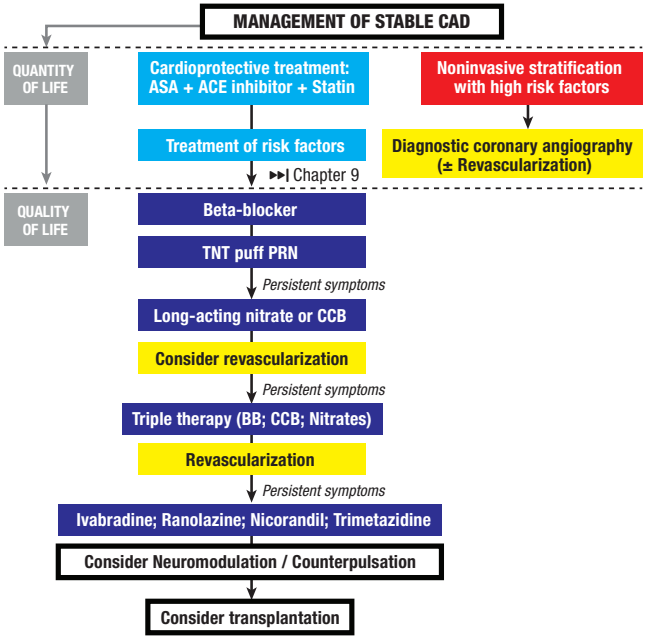


SENSITIVITY AND SPECIFICITY OF DIAGNOSTIC TESTS TO PREDICT SIGNIFICANT CORONARY ARTERY STENOSIS ON CORONARY ANGIOGRAPHY

	SENSITIVITY	SPECIFICITY
Stress test	68 %	77 %
MIBI–Stress	88 %	72 %
MIBI–Dipyridamole	90 %	75 %
Stress echocardiography	85 %	81 %
Dobutamine echocardiography	81 %	79 %
Coronary CT angiography	95 %	83 %

RISK ASSESSMENT DURING NONINVASIVE STRATIFICATION	
HIGH RISK (ANNUAL MORTALITY OR MYOCARDIAL INFARCTION > 3%)	• **LVEF**: < 35% at rest (coronary cause) • **LVEF**: LV dysfunction during stress with LVEF at peak stress < 45% or ↘ LVEF ≥ 10% • **LV dilatation during stress** • **Stress test:** Duke score ≤ -11 • **Stress test:** ST depression ≥ 2 mm (at low workload or persisting during recovery) or ST elevation or VT/VF on exercise • **Echocardiography**: regional wall motion abnormality during stress involving ≥ 3 segments and/or ≥ 2 vascular territories • **Echocardiography**: regional wall motion abnormality occurring at a low dose of Dobutamine (10 µg/kg/min) or at low HR (< 120 bpm) • **MIBI**: perfusion abnormality at rest involving ≥ 10% of the myocardium (in the absence of a history of MI) • **MIBI:** perfusion abnormality on stress involving ≥ 10% of the myocardium (or involving ≥ 2 vascular territories) • **Agaston score (non-contrast CT):** > 400 • **Coronary CT angiography**: multiple vessel disease (stenosis ≥ 70%) or LMCA involvement (stenosis ≥ 50%)
INTERMEDIATE RISK (ANNUAL MORTALITY OR MI: 1-3%)	• **LVEF**: 35-49% at rest (coronary cause) • **Stress test**: Duke score: -10 to +4 • **Stress test**: ST depression ≥ 1 mm + symptoms on exertion • **Echocardiography**: regional wall motion abnormality during stress on 1-2 segments (involving 1 vascular territory) • **MIBI**: perfusion abnormality at rest involving 5 to 9.9% of the myocardium (in the absence of a history of MI) • **MIBI**: perfusion abnormality on stress involving 5 to 9.9% of the myocardium (involving 1 vascular territory) • **Agaston score (non-contrast CT)**: 100-399 • **Coronary CT angiography**: 1 vessel with stenosis ≥ 70% (or ≥ 2 vessels with 50-69% stenosis)
LOW RISK (ANNUAL MORTALITY FROM MI < 1%)	• **Stress test:** Duke score ≥ +5 (or absence of ST abnormalities and symptoms with exercise achieving 85% of predicted HRmax) • **Echocardiography**: normal or limited regional wall motion abnormality at rest and unchanged during stress • **MIBI**: normal or small perfusion defect at rest or on stress involving < 5% of the myocardium • **Agaston score (non-contrast CT)**: < 100 • **Coronary CT angiography**: absence of stenosis > 50%

MANAGEMENT



CARDIOPROTECTIVE TREATMENT

TREATMENT IMPROVING SURVIVAL: **A) ACE inhibitors; B) ASA; C) Statin**

ASA (★ Antithrombotic Trialists' Collaboration); Plavix if allergy (★ CAPRIE)

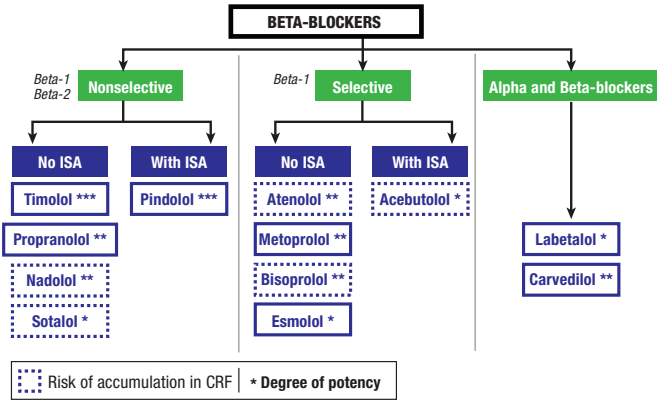
ACE INHIBITORS: ★ HOPE; ★ EUROPA; cardioprotective effect; particularly beneficial if LV dysfunction / DM / HTN / CRF

TREATMENT OF RISK FACTORS: **▸▸| Chapter 9**; HTN; Dyslipidemia (statins); DM; Smoking; Exercise program; Target healthy weight; Balanced diet

ANTI-ANGINAL TREATMENT

BB: **first-line**; antagonist of catecholamine adrenergic receptors; **negative inotropic and negative chronotropic agent** (↗ duration of diastole → ↗ coronary perfusion); anti-anginal; antihypertensive; antiarrhythmic +

› **Intrinsic sympathetic activity (ISA):** partially beta-agonist at rest



NITRATES: converted into NO in the cell → ↗ intracellular cGMP → smooth muscle relaxation (by decreasing intracellular Ca^{2+}); **veinodilatation** (↘ preload); **coronary vasodilatation** (↗ perfusion); **systemic arterial vasodilatation** (↘ afterload)

CALCIUM CHANNEL BLOCKERS

- **Dihydropyridines**: Nifedipine (★ ACTION); Amlodipine (★ CAMELOT); **systemic arterial vasodilatation** (↘ afterload); **coronary vasodilatation** (↗ perfusion)
- **Nondihydropyridines**: Verapamil; Diltiazem; **negative inotropic and negative chronotropic agent; systemic and coronary arterial vasodilatation**

IVABRADINE (PROCORALAN): sinus node I_f channel inhibitor; ↘ **HR** (↗ duration of diastole → ↗ coronary perfusion); ★ INITIATIVE; ★ ASSOCIATE; ★ SIGNIFY: no effect on CV death or MI (but ↗ primary end point among patients with angina of CCS class ≥ 2/4)

RANOLAZINE (RANEXA): ↘ myocyte calcium overload by I_{Na} inhibition; anti-anginal (★ CARISA; ★ ERICA; ★ MERLIN-TIMI 36)

NICORANDIL: 3 mechanisms: **A)** Opening of potassium channels of ischemic cells **(mimics ischemic preconditioning)**; **B)** Opening of potassium channels allowing **systemic and coronary arterial vasodilatation**; **C) Similar properties to Nitrates**

- ★ **IONA:** Stable CAD; ↘ primary outcome with Nicorandil (cardiovascular mortality - MI - hospitalization)

TRIMETAZIDINE (VASTAREL): **fatty acid oxidation inhibitor**; ★TRIMPOL II

EXTERNAL COUNTERPULSATION: 35 one-hour treatments for 7 weeks; cuffs on lower limbs that inflate in early diastole and deflate in pre-systole; ↗ **collateral circulation and/or angiogenesis and/or improvement of endothelial function**

- **Contraindications:** active DVT; PAD; Aortic aneurysm; Aortic stenosis; Aortic regurgitation; Uncontrolled HTN; Decompensated heart failure

NEUROMODULATION: Spinal cord stimulation (T1-T2); ↘ **nociceptive transmission to CNS**

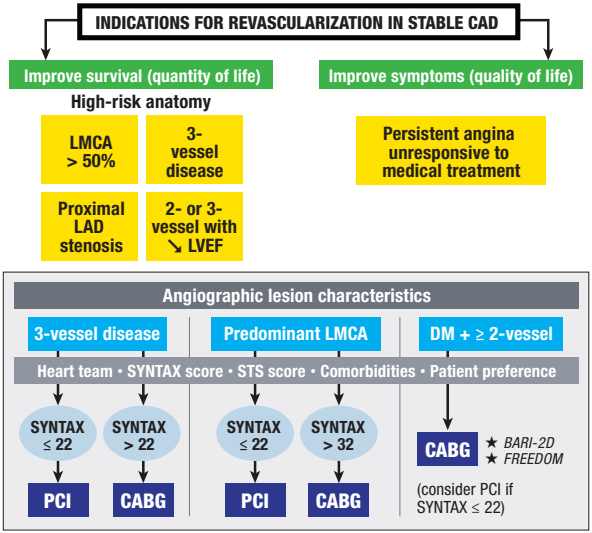
LASER MYOCARDIAL REVASCULARIZATION DURING CARDIAC SURGERY (THERAPEUTIC ANGIOGENESIS): **create subendocardial channels** by left intraventricular laser; consider during refractory angina in the presence of a nonrevascularizable ischemic territory; used exceptionally

ANTI–ANGINAL	DOSES	ADVERSE EFFECTS
BETA-BLOCKERS	**Target resting HR 50-60 bpm** **Maintenance dose** • Metoprolol: 50 - 100 mg bid • Bisoprolol: 2.5 - 10 mg qd • Carvedilol: 3.125 - 50 mg bid • Atenolol: 50 - 100 mg qd • Propranolol LA: 80 - 320 mg qd • Nadolol: 40 - 240 mg qd • Esmolol: Bolus IV 500 µg/kg; infusion 50 - 200 µg/kg/min	Bradycardia - Blocks; Negative inotropic agent (heart failure); Bronchospasm; Depression / Tiredness; Nightmares; Erectile dysfunction; masked symptoms of hypoglycemia (prefer Bisoprolol or Metoprolol); rebound ischemia after sudden discontinuation; Possible exacerbation of PAD or Raynaud or Prinzmetal (unopposed alpha stimulation); ↗ TG and ↘ HDL (nonselective BBs)
NITRATES	• Sublingual: 0.4 mg/puff every 5 min x 3 • Patch: 0.2 - 0.8 mg/h; 8:00 a.m. to 8:00 p.m. • Isosorbide 5-mononitrate (Imdur): 30 to 240 mg qd • Isosorbide dinitrate: 10 - 40 mg tid • IV: 5 - 200 µg/min	Headache; Flushing; Hypotension; Tolerance (prevention by 12-hour period without TNT each day); Methemoglobinemia; Interaction with PDE5 inhibitors; Avoid in the presence of aortic stenosis or HCM
DIHYDROPYRIDINE CCBS	• Nifedipine SR (long-acting): 30 - 60 - 90 mg qd • Amlodipine: 2.5 - 10 mg qd	Headache; Faintness; Hypotension; Flushing; Leg edema
NONDIHYDRO-PYRIDINE CCBS	**Diltiazem** • PO: 30 - 90 mg tid-qid • CD: 120 - 360 mg qd • Bolus: 0.25 mg/kg IV • Infusion: 5 - 15 mg/h **Verapamil** • PO: 80 - 120 mg tid-qid • SR: 120 - 480 mg qd • Bolus: 0.075 - 0.15 mg/kg	Block; Bradycardia; Heart failure (negative inotropic agent); Hypotension; Flushing; Headache; Leg edema; Drug interactions
IVABRADINE	• 5 to 7.5 mg bid	Bradycardia; Phosphenes
NICORANDIL	• 10-20 mg bid	Ulcers; Nausea; Hypotension; Headache; Weakness; Flushing
TRIMETAZIDINE	• 20 mg tid or 30 mg bid	Nausea; Vomiting; Parkinsonism
RANOLAZINE	• 500 to 1000 mg bid	Drug interactions; Nausea; Weakness; ↗ QT (but ↘ delayed after-depolarizations)

REVASCULARIZATION

2 OBJECTIVES

a) Improve quantity of life (prognosis)
b) Improve quality of life (symptoms)



FACTORS AFFECTING THE PATIENT'S PROGNOSIS

a) **Markers of high risk on noninvasive stratification**
b) **Significant ischemia (> 10% of LV)**
c) **LV dysfunction**
d) **Anatomical extent of CAD / Number of vessels involved**

BENEFITS OF CABG VERSUS MEDICAL TREATMENT ON SURVIVAL: **A) LMCA; B) 3 vessels; C) 2 vessels with proximal LAD** (★ Yusuf; ★ VA Cooperative; ★ CASS; ★ ECSS)

PCI VERSUS MEDICAL TREATMENT: ★ **COURAGE** → Stable CAD (30% with proximal LAD) → PCI vs medical treatment; similar survival and infarction rates; ↘ **angina with PCI**

CABG VERSUS PCI: **similar mortality and infarction rates (in patients eligible for both procedures)**; ↗ reintervention with PCI; ↗ Procedural stroke with CABG (★ EAST; ★ BARI; ★ ARTS; ★ SOS; ★ BEST)

★ **SYNTAX**: 3-vessel CAD or LMCA (eligible for both procedures) → CABG vs PCI; **similar mortality**; ↗ MI and ↗ reintervention with PCI

SYNTAX score ≤ 22	SYNTAX score 23–32	SYNTAX score ≥ 33
Similar primary outcome with CABG and PCI	↗ adverse events with PCI	↗ adverse events with PCI

CABG VERSUS PCI FOR LMCA: ★ SYNTAX subgroup **(patients eligible for both procedures)**: ↗ reintervention with PCI; ↗ Procedural stroke with CABG

2.2/ BIOMARKERS

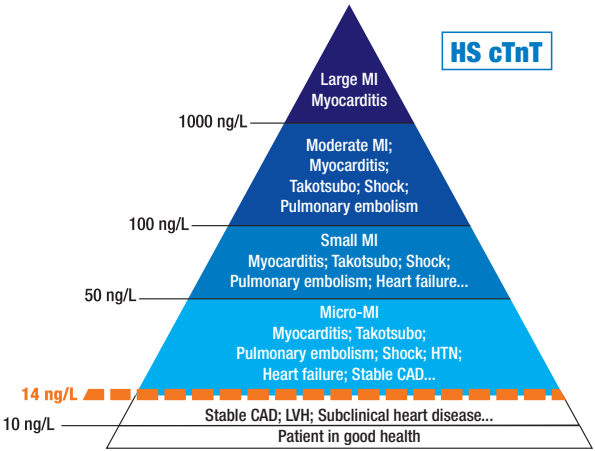
Released following myocyte necrosis (myocyte injury)

TROPONINS T AND I (CTNT AND CTNI): very sensitive and specific for myocyte necrosis **but not very specific for myocardial infarction (ischemic myocyte necrosis)**

MYOCYTE NECROSIS = LABORATORY DIAGNOSIS
MYOCARDIAL INFARCTION = CLINICAL DIAGNOSIS

DIFFERENTIAL DIAGNOSIS OF ELEVATED TROPONIN

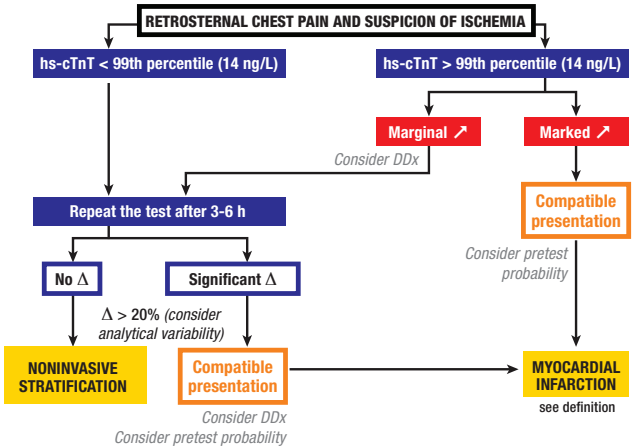
- Infarction
- Heart failure
- Bradyarrhythmia or Tachyarrhythmia
- Myocarditis
- Pulmonary embolism
- Aortic valve disease
- Myocardial contusion
- Takotsubo
- Infiltrative cardiomyopathy
- HCM
- Hypertensive crisis
- Aortic dissection
- Coronary vasospasm
- Endothelial dysfunction without CAD
- PCI
- Cardiac surgery
- Balloon valvuloplasty
- ECV / Defibrillation
- Electrophysiological ablation
- Graft rejection
- Sepsis
- Renal failure
- Significant PHT
- Severe anemia
- Respiratory failure
- Intense physical exercise
- Cardiotoxic chemotherapy
- Cardiotoxins
- Subarachnoid hemorrhage
- Acute brain syndrome
- Rhabdomyolysis
- Body burn (> 30% BSA)
- Scorpion venom



STANDARD TROPONIN: obtain a baseline value on arrival in the emergency room (0 h) and ≥ 1 value **> 6-9 h** after onset of chest pain

HIGH-SENSITIVITY TROPONIN: First troponin assay on arrival → sensitivity and specificity of 90% and NPV of 97%

› **If hs-cTn negative on arrival (0 h) and 3-6 h after arrival with no significant difference between the two tests (< 20%) → NPV of 99%** +



REINFARCTION: assay Troponin at 0h - 3h - 6h; **diagnosis of reinfarction if ↗ ≥ 20%** + (when cTn > 99th percentile pre-reinfarction but with stable or ↘ level)

	INITIAL ELEVATION	PEAK	RETURN TO NORMAL
CK-MB	3-12 h	24 h	48-72 h
Troponin I	3-12 h	24 h	5-10 d
Troponin T	3-12 h	12 h-48 h	5-14 d
Myoglobin	1-4 h	6-7 h	24 h

2.3/ MYOCARDIAL INFARCTION: DEFINITION

NECROSIS OF THE MYOCARDIUM IN THE PRESENCE OF MYOCARDIAL ISCHEMIA

DIAGNOSTIC CRITERIA

Detection of ↗ and/or ↘ of a cardiac biomarker (preferably cTn) with ≥ 1 value > 99th percentile (coefficient of variation of the test ≤ 10%) in the presence of myocardial ischemia **+** **≥ 1 of the following elements**	• **Symptoms** compatible with **ischemia** • Δ **ECG changes** compatible with **ischemia** (Δ ST-T abnormalities) or *de novo* LBBB • *De novo* pathological **Q waves** • **Imaging:** loss of viable myocardium or *de novo* RWMA • Intracoronary **thrombus** (on coronary angiography or at autopsy) +

CLASSIFICATION

TYPE 1	**Acute coronary syndrome: primary coronary event** • Plaque rupture / erosion / ulceration; Coronary dissection
TYPE 2	**Infarction secondary to O_2 supply and demand imbalance** • Anemia; Hypoxemia; Arrhythmia; HTN; Hypotension; Cocaine; Coronary spasm; Endothelial dysfunction; Coronary embolism
TYPE 3	**Cardiac arrest / Sudden death** • Symptoms suggestive of ischemia + • Δ ECG changes compatible with ischemia or *de novo* LBBB + • No biomarker assays
TYPE 4a	**Infarction secondary to PCI** • Symptoms suggestive of ischemia or ischemic ECG changes or angiographic findings compatible with procedural complication or imaging compatible with loss of viable myocardium or *de novo* RWMA + • Positive biomarkers a) ↗ cTn **≥ 5 x upper limit of normal** (> 99th percentile) when baseline cTn normal (< 99th percentile) or b) ↗ cTn **> 20 %** when baseline value elevated (> 99th percentile) but stable
TYPE 4b	**Infarction secondary to stent thrombosis**
TYPE 5	**Infarction secondary to CABG** • ↗ cTn **≥ 10 x upper limit of normal** (> 99th percentile) when baseline cTn normal (< 99th percentile) + • *De novo* Q waves or de novo LBBB or new coronary (or CABG) occlusion on coronary angiography or imaging compatible with loss of viable myocardium or *de novo* RWMA

CAUSES OF INFARCTION IN THE ABSENCE OF ATHEROSCLEROSIS

O_2 SUPPLY/DEMAND IMBALANCE: AS; AR; CO poisoning; Hyperthyroidism; Prolonged hypotension; Hypertensive crisis; Sepsis - Fever; Anemia; Respiratory failure; AV fistula; HCM; Tachyarrhythmia; Cocaine; Endothelial dysfunction

CORONARY EMBOLISM: Endocarditis (infective or non-infective); MVP; Intracardiac thrombus; Prosthetic valve; Myxoma; Iatrogenic; Paradoxical embolism; Fibroelastoma; Valvular calcification

ARTERITIS: Syphilis; SLE; Takayasu (coronary ostium); PAN; Kawasaki; RA; Ankylosing spondylitis; Giant cell arteritis; Scleroderma

› **SLE:** Arteritis; endothelial dysfunction; thrombosis (antiphospholipid syndrome); accelerated atherosclerosis; coronary aneurysm

TRAUMA: Laceration; Iatrogenic; Radiotherapy; Contusion

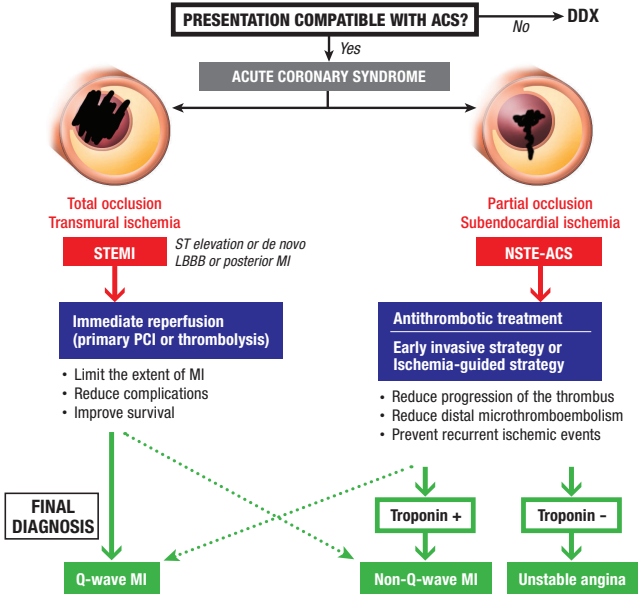
INFILTRATIVE / PROLIFERATIVE: Hurler's; Homocysteinuria; Fabry; Amyloidosis; Pseudoxanthoma elasticum

CONGENITAL: ALCAPA; Anomalous coronary origin; Coronary fistula; Coronary aneurysm

HEMATOLOGICAL (*IN SITU* THROMBOSIS): Hyperviscosity; Polycythemia; Thrombocytosis; Hypercoagulable state - Antiphospholipid syndrome; TTP; DIC

OTHER: Prinzmetal; Aortic dissection; Coronary dissection (pregnancy; Marfan; Ehlers-Danlos; Cocaine); Takotsubo; Thrombosis then spontaneous thrombolysis; Medications; Myocardial bridge

2.4/ UNSTABLE ANGINA & NSTEMI



IN-HOSPITAL MORTALITY of STEMI is 50% higher than that of NSTEMI

› **Similar one-year mortality for STEMI and NSTEMI** (high risk of recurrent events after NSTEMI)

PATHOPHYSIOLOGY: Rupture / Erosion of an unstable and friable atherosclerotic plaque with exposure of the subendothelial matrix then activation of primary and secondary hemostasis and thrombus formation

ASSESSMENT

SYMPTOMS OF ACS	UNSTABLE NATURE
Retrosternal chest pain* • **Nature:** Constrictive - Tightness • **Radiation**: Neck - Jaw - Upper limb • **Associated symptoms**: Dyspnea; Nausea; Vomiting; Diaphoresis * Atypical presentation / Anginal equivalent in elderly - DM - women	**Any one of the following**: • ***De novo* angina** < 2 months after presentation with CCS ≥ 3/4 • **Crescendo angina**: more frequent or longer or on less exertion (with CCS ≥ 3/4) • **Angina at rest** (often lasting > 20 min) < 1 week after presentation

CLINICAL FEATURES: Diaphoresis; Cold skin; Sinus tachycardia; PVCs; ± Hypotension; S3 or S4; Ischemic MR murmur; Crackles

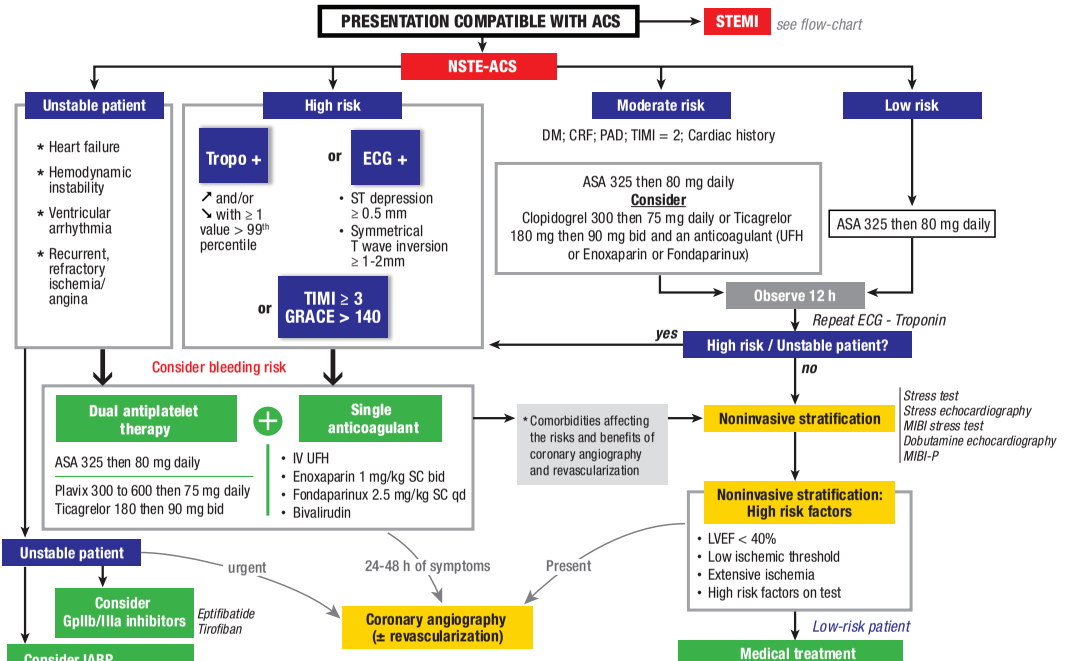
ECG

ST depression	• Horizontal or descending • **≥ 0.5 mm** (≥ 2 contiguous leads)
T–wave inversion	• **≥ 1-2 mm** (≥ 2 contiguous leads) › Leads with R/S > 1

NSTE–ACS AND UNSTABLE ANGINA

HIGH RISK (≥ 1 CRITERION)	INTERMEDIATE RISK (≥ 1 CRITERION)	LOW RISK
Unstable atherosclerotic plaque; Urgent evaluation		**Outpatient stratification possible**
• Accelerated angina < 48 h • Prolonged and persistent retrosternal chest pain at rest (> 20 min) • Ischemic pulmonary overload • *De novo* MR murmur • S3 or Crackles • Hypotension or Bradycardia or Tachycardia • Age > 75 years • Angina at rest with transient ST changes > 0.5 mm • *De novo* bundle branch block • Sustained VT • Significant elevation of troponins	• History: myocardial infarction or PAD or cerebrovascular disease or history of CABG • Treatment with ASA • Prolonged retrosternal chest pain at rest (> 20 min) but resolved • Prolonged retrosternal chest pain (> 20 min), but resolved with rest or TNT • Nocturnal angina • CCS III or IV angina (*de novo* or progressive) < 2 weeks without prolonged retrosternal chest pain at rest (> 20 min) • Age > 70 years • T wave abnormalities • Pathological Q waves or ST depression at rest < 1 mm on multiple leads • Marginal elevation of troponins	• More frequent or more severe or more persistent angina • Angina induced by a lower workload • *De novo* angina: between 2 weeks to 2 months before presentation • Normal ECG • Normal troponin

TIMI SCORE	GRACE SCORE
1) Age > 65 years 2) ≥ 3 risk factors for CAD 3) Known stenosis > 50% 4) ASA < 7 days 5) ≥ 2 episodes of retrosternal chest pain x 24 h 6) ST depression ≥ 0.5 mm 7) Biomarkers **Death / MI / Urgent revascularization within 14 days** 0-1 point.....4.7 % 2 points .....8.3 % 3 points .....13.2 % 4 points .....19.9 % 5 points .....26.2 % 6-7 points.....40.9 %	www.gracescore.org 1) Age 2) SBP 3) HR 4) Killip Class 5) Heart failure 6) Cardiac arrest at presentation 7) ST segment depression 8) Biomarkers 9) Creatinine **In–hospital mortality** GRACE ≤ 108 points.....< 1 % GRACE 109-140 points .....1-3 % GRACE > 140 points .....> 3 %



PRESENTATION COMPATIBLE WITH ACS
STEMI
see flow-chart
NSTE-ACS
Unstable patient
* Heart failure
* Hemodynamic instability
* Ventricular arrhythmia
* Recurrent, refractory ischemia/ angina
High risk
Tropo +
or
ECG +
↗ and/or ↘ with ≥ 1 value > 99th percentile
• ST depression ≥ 0.5 mm
• Symmetrical T wave inversion ≥ 1-2mm
or
TIMI ≥ 3
GRACE > 140
Moderate risk
DM; CRF; PAD; TIMI = 2; Cardiac history
Low risk
ASA 325 then 80 mg daily
Consider
Clopidogrel 300 then 75 mg daily or Ticagrelor 180 mg then 90 mg bid and an anticoagulant (UFH or Enoxaparin or Fondaparinux)
ASA 325 then 80 mg daily
Observe 12 h
Repeat ECG - Troponin
yes
High risk / Unstable patient?
no
Consider bleeding risk
Dual antiplatelet therapy
ASA 325 then 80 mg daily
Plavix 300 to 600 then 75 mg daily
Ticagrelor 180 then 90 mg bid
Single anticoagulant
• IV UFH
• Enoxaparin 1 mg/kg SC bid
• Fondaparinux 2.5 mg/kg SC qd
• Bivalirudin
* Comorbidities affecting the risks and benefits of coronary angiography and revascularization
Noninvasive stratification
Stress test
Stress echocardiography
MIBI stress test
Dobutamine echocardiography
MIBI-P
Noninvasive stratification: High risk factors
• LVEF < 40%
• Low ischemic threshold
• Extensive ischemia
• High risk factors on test
Low-risk patient
Medical treatment
Unstable patient
urgent
24-48 h of symptoms
Present
Consider GpIIb/IIIa inhibitors
Eptifibatide
Tirofiban
Consider IABP
Coronary angiography (± revascularization)

INITIAL MANAGEMENT

ARRIVAL IN THE EMERGENCY ROOM: ECG within 10 min; IV lines; Monitor; ASA 325 mg; Sublingual TNT (except when contraindicated); O_2 (for SaO2 > 90%); ± Morphine 2.5 mg IV if persistent chest pain

CHOICE OF STRATEGY

EARLY INVASIVE STRATEGY	ISCHEMIA–GUIDED STRATEGY
↘ Mortality; ↘ MI; ↘ Hospitalization (★ FRISC-II; ★ RITA-3; ★ TACTICS-TIMI 18)	**According to non–invasive stress test (★ ICTUS)**
• **Unstable patient** (urgent coronary angiography) › Acute heart failure › Hemodynamic instability › Ventricular arrhythmia › Recurrent and refractory angina/ischemia • **Troponin +** • **Positive ECG** (*De novo* ST depression) • Patient at high risk of recurrent events › **TIMI ≥ 3** › **GRACE > 140** • **PCI < 6 months** (rule out restenosis) • **History of CABG** (multiple anatomical possibilities)	• **TIMI score 0-1** • **GRACE < 109** • **Risk of complications** associated with coronary angiography and/or revascularization • **Comorbidities; Frailty** • Patient's **preference**

DUAL ANTIPLATELET THERAPY

ASA: Irreversible inhibitor of COX-1 (and TXA synthesis)
› ★ **Antithrombotic Trialists**: ↘ all-cause mortality; ↘ recurrent ischemic events
› **Dose:** 325 mg then 80 mg qd (★ CURRENT-OASIS 7)

CLOPIDOGREL: Second-generation thienopyridine; irreversible ADP $P2Y_{12}$ receptor antagonist
› ★ **CURE**: ↘ recurrent ischemic events (**at 12 months**); ↗ major bleeding
› ★ **CURRENT-OASIS 7**: High-dose clopidogrel (600 mg then 150 mg qd for 6 days then 75 mg qd) versus standard doses (300 mg then 75 mg qd) → potential benefit in **the subgroup of patients undergoing PCI** (but ↗ bleeding risk)
› **Disadvantage**: **A)** Slow onset of action (requires 2 metabolism and activation steps); **B)** Genetic polymorphisms of the cytochrome P450 enzyme responsible for metabolism (and activation) of clopidogrel (some patients metabolize and activate the medication less effectively); **C)** Inhibits 50-60% of platelets

TICAGRELOR: Reversible direct $P2Y_{12}$ receptor antagonist; rapid onset of action
› ★ **PLATO**: Ticagrelor versus clopidogrel (**47% of patients had received clopidogrel prior to randomization**); Revascularization or medical treatment → ↘ **all-cause mortality**; ↘ recurrent ischemic events; ↗ major bleeding not related to CABG
› **Adverse effects**: Dyspnea; ↗ ventricular pauses; ↗ creatinine (reversible)
› **Contraindication**: History of intracranial bleeding; active bleeding; severe liver disease; potent CYP3A4 inhibitor
› ★ **PEGASUS**: Ticagrelor (60 or 90 mg bid) versus Placebo in patients with a myocardial infarction 1-3 years earlier; ↘ **CV death - MI - Stroke but ↗ major bleeding**

PRASUGREL: **no benefit** in ★ ACCOAST (upfront therapy) and ★ TRILOGY ACS (ischemia-guided strategy)

GPIIB/IIIA INHIBITORS : Block the formation of bridges between platelets (cross-links between GPIIb/IIIa receptors and fibrinogen)

- ★ **EARLY-ACS**: **no benefit** of eptifibatide initiated routinely > 12 h before coronary angiography versus eptifibatide initiated on demand during PCI
- **Consider the use of GPIIb/IIIa inhibitors** in patients treated with Ticagrelor (or Prasugrel): **during PCI for bailout situations / thrombotic complications**
  - **Eptifibatide**: **A)** Bolus: 180 µg/kg IV then 2nd bolus of 180 µg/kg within 10 min; **B)** Infusion: 2 µg/kg/min (initiated after 1st bolus); decrease the dose by 50% if GFR < 50 mL/min
  - **Tirofiban**: **A)** Bolus: 25 µg/kg IV; **B)** Infusion: 0.15 µg/kg/min; decrease the dose by 50% if GFR < 30 mL/min
  - **Abciximab**: **A)** Bolus: 0.25 mg/kg IV; **B)** Infusion: 0.125 µg/kg/min (max 10 µg/min)
- **Adverse effects**: thrombocytopenia; bleeding

ANTICOAGULATION

Avoid crossover between antithrombins; stop anticoagulation after PCI (unless otherwise indicated)

UNFRACTIONATED HEPARIN

- ★ **Eikelboom meta-analysis**: ↘ mortality (before the age of dual antiplatelet therapy and early revascularization)
- **Doses:** 60 IU/kg bolus then 12 IU/kg/h; PTT every 6 h; target PTT 50-70 s (1.5 to 2 x control)
  - **During coronary angiography:** additional UFH as needed (2000-5000 U); **A)** Absence of GPIIb/IIIa inhibitors→ target ACT 250-300 s (HemoTec) or 300-350 s (Hemochron); **B)** Presence of GPIIb/IIIa inhibitors → target ACT 200-250 s
- **Complications:** bleeding; HIT (consider Bivalirudin)

ENOXAPARIN (LMWH): Xa inhibitor and weak thrombin inhibitor (factor IIa inhibitor)

- ★ **SYNERGY**: Enoxaparin vs Unfractionated heparin →↗ **bleeding** during early invasive strategy with enoxaparin
- **Doses:** 1 mg/kg SC bid (reduce to once daily if GFR < 30 mL/min)
- **PCI:** Last dose > 8 h → 0.3 mg/kg IV bolus

FONDAPARINUX: indirect Xa inhibitor

- ★ **OASIS-5**: Fondaparinux vs enoxaparin →↘ bleeding;↘ all-cause mortality; ↗ **catheter thrombosis during PCI** (as it does not act on already formed thrombin)
- **Doses:** 2.5 mg SC once daily (avoid if GFR < 20 mL/min)
- **PCI:** Add a bolus of unfractionated heparin (70-85 IU/kg; 50-60 IU/kg with concomitant GPIIb/IIIa inhibitors)

BIVALIRUDIN: thrombin inhibitor (factor IIa inhibitor)

- ★ **ACUITY:** Bivalirudin vs unfractionated heparin + GPIIb/IIIa inhibitors → non-inferiority for primary outcome; ↘ major bleeding
- ★ **MATRIX**: ACS with PCI anticipated; Bivalirudin vs unfractionated heparin → no benefit
- **Dose**: **A)** Bolus: 0.1 mg/kg; **B)** Infusion: 0.25 mg/kg/h
  - **During PCI: A)** Bolus: 0.5 mg/kg; **B)** Infusion: 1.75 mg/kg/h

RIVAROXABAN: oral Xa inhibitor

- ★ **ATLAS ACS-TIMI 51:** Recent ACS on dual antiplatelet therapy; Rivaroxaban (2.5 or 5 mg bid; initiated an average of 4.5 days post-ACS) vs placebo; ↘ recurrent ischemic events; ↘ **all-cause mortality (2.5 mg bid)**; ↗ major bleeding
- **Consider:** in combination with ASA and Clopidogrel (if Ticagrelor or Prasugrel are not available) in patients with high ischemic and low bleeding risks

URGENT CORONARY ANGIOGRAPHY	EARLY INVASIVE STRATEGY (< 48 H)	ISCHEMIA–GUIDED STRATEGY
1) ASA 325 mg **2)** Ticagrelor 180 mg **or** Clopidogrel 600 mg **3)** ± GpIIb/IIIa inhibitors (during PCI for bailout situations) **4)** Unfractionated heparin	**1)** ASA 325 mg **2)** Ticagrelor 180 mg then 90 mg bid **or** Clopidogrel 300 mg then 75 mg qd (consider an additional 300 mg if PCI then 150 mg qd for 6 days then 75 mg) **3)** Unfractionated heparin or Enoxaparin or Fondaparinux or Bivalirudin › Stop after PCI in the absence of complications	**1)** ASA 325 mg **2)** Ticagrelor 180 mg then 90 mg bid **or** Clopidogrel 300 mg then 75 mg qd (consider an additional 300 mg if PCI then 150 mg qd for 6 days then 75 mg) **3)** Unfractionated heparin (48 h or until PCI is performed) or Enoxaparin or Fondaparinux if bleeding risk (for the duration of hospitalization or until PCI is performed)

- **Patient already on Clopidogrel:** another loading dose of 300 to 600 mg if PCI planned
- **Patient on Warfarin**: wait for INR < 2.0-2.5 before starting anticoagulant

2.5/ ST SEGMENT ELEVATION MYOCARDIAL INFARCTION (STEMI)

ECG CRITERIA

ST ELEVATION (FROM POINT J IN ≥ 2 CONTIGUOUS LEADS)	
V2 – V3	• Male ≥ 40 years: ≥ 2 mm • Male < 40 years: ≥ 2.5 mm • Female: ≥ 1.5 mm
All other leads	≥ 1 mm
V3R – V4R – V7 – V8 – V9	≥ 0.5 mm

DDX OF ST ELEVATION		
Male ST pattern	• 90% of men < 35 years • Concave ST elevation > 1 mm in V1 to V3 (especially V2)	
Early repolarization	• Large T waves (especially in V4) • ST elevation in V2-V3-V4 (concave) • Notch at point J • PR segment depression	Juvenile T wave pattern and early repolarization	• T wave inversion (juvenile T wave pattern) combined with early repolarization • Short QT	LVH	• Concave ST elevation in V1 to V3 • Positive voltage criteria	Post–MI with aneurysm	• Persistent ST elevation (> 3 weeks post-MI) in the presence of Q waves	LBBB (or paced rhythm)	• Concave ST elevation; the ST deviation is discordant with the QRS axis **Sgarbossa criteria** (infarction in the presence of LBBB) 1) **ST elevation ≥ 1 mm in leads with positive QRS (inappropriate concordance)** - Criterion with the best predictive value 2) ST depression ≥ 1 mm V1-V2-V3 (inappropriate concordance) 3) ST elevation ≥ 5 mm in leads with negative QRS (extreme discordance)	
Acute pericarditis	• Diffuse concave ST elevation (multiple anatomical territories) • PR segment depression • Reciprocal changes in aVR	
Brugada syndrome	• rSR' and ST elevation in V1 and V2 with descending slope and T wave inversion	
Hyperkalemia	• Peaked and symmetrical T waves • ST elevation • Other signs: Wide QRS; decreased amplitude of P waves; blocks; asystole	Pulmonary embolism	• T wave inversion and ST elevation in right precordial and inferior leads • S1 Q3 T3 • RBBB • Sinus tachycardia	
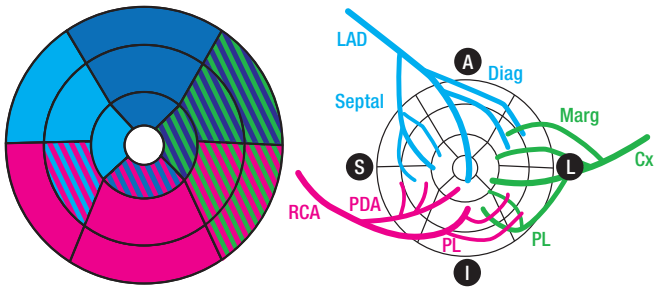
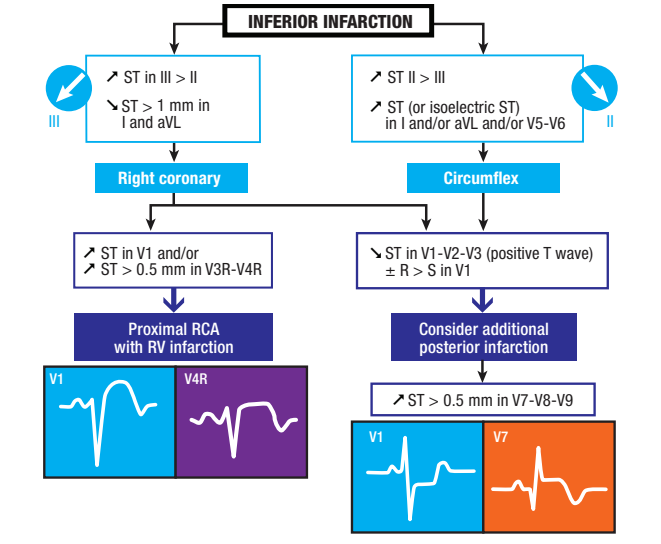
SITE OF INFARCTION ON ECG

I Lateral	aVR	V1 Antero-septal	V4 Anterior
II Inferior	aVL Lateral	V2 Antero-septal	V5 Antero-lateral
III Inferior	aVF Inferior	V3 Anterior	V6 Antero-lateral

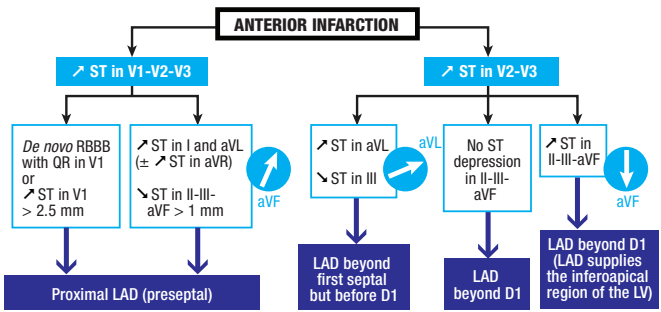
V3R-V4R Right heart

V7-V8-V9 Posterior

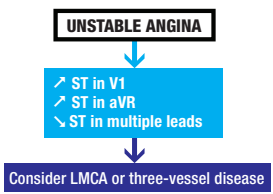




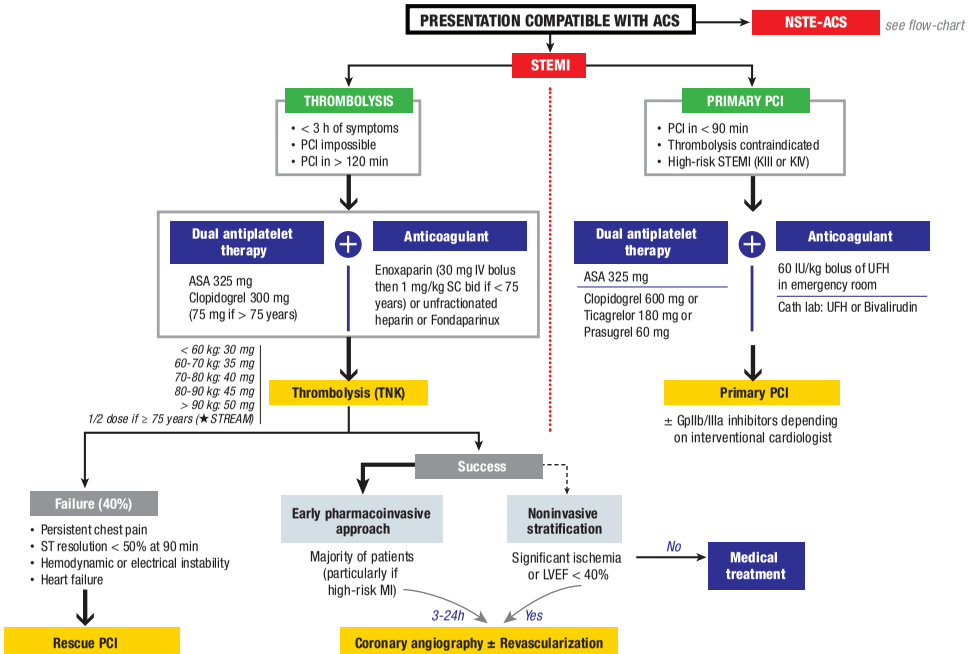
INFERIOR INFARCTION
↗ ST in III > II
↘ ST > 1 mm in I and aVL
III
↗ ST II > III
↗ ST (or isoelectric ST) in I and/or aVL and/or V5-V6
II
Right coronary
Circumflex
↗ ST in V1 and/or ↗ ST > 0.5 mm in V3R-V4R
↘ ST in V1-V2-V3 (positive T wave) ± R > S in V1
Proximal RCA with RV infarction
Consider additional posterior infarction
V1
V4R
↗ ST > 0.5 mm in V7-V8-V9
V1
V7



ANTERIOR INFARCTION
↗ ST in V1-V2-V3
↗ ST in V2-V3
De novo RBBB with QR in V1 or ↗ ST in V1 > 2.5 mm
↗ ST in I and aVL (± ↗ ST in aVR)
↘ ST in II-III-aVF > 1 mm
aVF
↗ ST in aVL
↘ ST in III
aVL
No ST depression in II-III-aVF
↗ ST in II-III-aVF
aVF
Proximal LAD (preseptal)
LAD beyond first septal but before D1
LAD beyond D1
LAD beyond D1 (LAD supplies the inferoapical region of the LV)



UNSTABLE ANGINA
↗ ST in V1
↗ ST in aVR
↘ ST in multiple leads
Consider LMCA or three-vessel disease



PRESENTATION COMPATIBLE WITH ACS
NSTE-ACS
see flow-chart
STEMI
THROMBOLYSIS
• < 3 h of symptoms
• PCI impossible
• PCI in > 120 min
PRIMARY PCI
• PCI in < 90 min
• Thrombolysis contraindicated
• High-risk STEMI (KIII or KIV)
Dual antiplatelet therapy
ASA 325 mg
Clopidogrel 300 mg
(75 mg if > 75 years)
Anticoagulant
Enoxaparin (30 mg IV bolus then 1 mg/kg SC bid if < 75 years) or unfractionated heparin or Fondaparinux
Dual antiplatelet therapy
ASA 325 mg
Clopidogrel 600 mg or
Ticagrelor 180 mg or
Prasugrel 60 mg
Anticoagulant
60 IU/kg bolus of UFH in emergency room
Cath lab: UFH or Bivalirudin
< 60 kg: 30 mg
60-70 kg: 35 mg
70-80 kg: 40 mg
80-90 kg: 45 mg
> 90 kg: 50 mg
1/2 dose if ≥ 75 years (★ STREAM)
Thrombolysis (TNK)
Primary PCI
± GpIIb/IIIa inhibitors depending on interventional cardiologist
Success
Failure (40%)
• Persistent chest pain
• ST resolution < 50% at 90 min
• Hemodynamic or electrical instability
• Heart failure
Early pharmacoinvasive approach
Majority of patients (particularly if high-risk MI)
Noninvasive stratification
Significant ischemia or LVEF < 40%
No
Medical treatment
3-24h
Yes
Rescue PCI
Coronary angiography ± Revascularization

INITIAL MANAGEMENT

EMERGENCY ROOM: ECG within 10 min; IV lines; Monitor; ASA 325 mg; Sublingual TNT (except when contraindicated); O_2 (for $SaO_2 > 90\%$); ± Morphine 2.5 mg IV if persistent chest pain

KILLIP CLASSIFICATION

Killip I	No crackles; No S3
Killip II	Crackles (< 50% of lung fields) ± S3
Killip III	Crackles > 50% of lung fields
Killip IV	Cardiogenic shock

TIMI SCORE IN STEMI

CRITERIA	# POINTS	30-DAY MORTALITY
Age 65-74 years or ≥ 75 years	2 or 3 points	**0 : 0.8 %**
SBP < 100	3 points	**1 : 1.6 %**
HR > 100 bpm	2 points	**2 : 2.2 %**
Killip II-III-IV	2 points	**3 : 4.4 %**
History: DM or HTN or Angina	1 point	**4 : 7.3 %**
< 67 kg	1 point	**5 : 12.4 %**
Time to treatment > 4 h	1 point	**6 : 16.1 %**
Anterior STEMI or LBBB	1 point	**7 : 23.4 %**
		8 : 26.8 %
		> 8 : 35.9 %

IMMEDIATE REPERFUSION

THROMBOLYSIS	PRIMARY PCI
< 30 min after 1st medical contact*	**< 90 min after 1st medical contact***
↘ Mortality (vs Placebo) **(★ GISSI; ★ ISIS-2; ★ ASSET)**	**↘ Mortality (vs Thrombolysis)** **↘ Recurrent infarction** **↘ Risk of intracranial hemorrhage**
Fibrinolysis less effective > 6 h after symptom onset • Early presentation: < 3 h of symptoms • Significantly delayed PCI (1st medical contact until PCI **> 120 min**) • PCI impossible (cath lab not available; vascular access impossible)	• PCI available in < 90 min after 1st medical contact • > 3 h of symptoms • Contraindication to thrombolysis - Bleeding risk / Intracranial bleeding • High-risk STEMI • Doubtful diagnosis

*** Including paramedics**

THROMBOLYSIS

TENECTEPLASE (TNK): < 60 kg → 30 mg; 60-70 kg → 35 mg; 70-80 kg → 40 mg; 80-90 kg → 45 mg; ≥ 90 kg → 50 mg; **if ≥ 75 years → half dose** (★STREAM)

› ★ **ASSENT-2:** Tenecteplase vs tPA → ↘ major bleeding with TNK

TIME TO ADMINISTRATION: **maximum benefit on mortality < 2-3 h of symptoms**

- ↘ **Response of thrombus** to thrombolysis **after > 3 h of symptoms**
- It is reasonable to perform thrombolysis up to 12-24 h after onset of symptoms in the presence of persistent ischemia (angina and ↗ ST on ECG) and significant infarction
  - ★ LATE - ★ EMERAS: ↘ **mortality between 6-12 h of symptoms**

ABSOLUTE CONTRAINDICATIONS	RELATIVE CONTRAINDICATIONS
• History of intracranial hemorrhage • Structural CNS vascular disease • Intracranial neoplasm • Stroke < 3 months • Suspicion of aortic dissection • Active bleeding (excluding menstruation) or bleeding diathesis • Significant facial / head trauma < 3 months • Intracranial or spinal cord surgery < 2 months • Severe refractory HTN	• SBP > 180 mmHg and/or DBP > 110 mmHg • Stroke > 3 months or dementia or intracranial disease • CPR > 10 min or traumatic • Major surgery < 3 weeks • Internal bleeding < 2-4 weeks • Noncompressible vascular puncture • Pregnancy • Active peptic ulcer • Oral anticoagulant
• Risk of intracranial bleeding → **Prefer PCI if ≥ 2 criteria present** **1)** > 65 years; **2)** BP > 160-170/95; **3)** M < 70 kg and F < 65 kg	

PRIMARY PCI: ADJUVANT TREATMENT

ASA: 325 mg then 80 mg qd

CLOPIDOGREL: 600 mg then 75 mg qd

PRASUGREL: Third-generation thienopyridine; irreversible inhibition of the $P2Y_{12}$ receptor; one-step activation (versus 2 steps for clopidogrel); metabolism not affected by genetic polymorphisms of cytochrome P450 enzymes

- ★ **TRITON-TIMI 38: thienopyridine-naive patients; known coronary anatomy** (except if primary PCI) → ↘ ischemic events; ↘ stent thrombosis; ↗ major bleeding
- **Avoid in patients**: **> 75 years; < 60 kg; History of stroke - TIA**

TICAGRELOR

- ★ **PLATO**: Clopidogrel-naive or non-naive patients; ↘ all-cause mortality; ↘ recurrent ischemic events; ↘ stent thrombosis; ↗ major bleeding not related to CABG

GPIIB/IIIA INHIBITORS: in the cath lab at **the interventional cardiologist's discretion** (significant thrombus; insufficient prior antiplatelet treatment; slow- or no-reflow; thrombotic complication)

- **Abciximab**: **A)** Bolus: 0.25 mg/kg IV; **B)** Infusion: 0.125 µg/kg/min

UNFRACTIONATED HEPARIN: 60 IU/kg bolus (max 4000 IU) then IV infusion with target aPTT of 50-70 s (12 IU/kg/h; max 1000 IU/h)

- **During coronary angiography**: **A)** Absence of GPIIb/IIIa inhibitors → target ACT 250-300 s (HemoTec) or 300-350 s (Hemochron); **B)** Presence of GPIIb/IIIa inhibitors → target ACT 200-250 s

BIVALIRUDIN: Thrombin inhibitor; used in cath lab

- ★ **HORIZONS-AMI**: Bivalirudin vs UFH + GPIIb/IIIa inhibitors; ↘ **all-cause mortality**; ↘ major bleeding
- ★ **MATRIX**: ACS (55% STEMI) with PCI anticipated; Bivalirudin vs UFH → no benefit with Bivalirudin
- **Dose**: **A)** Bolus: 0.75 mg/kg; **B)** Infusion: 1.75 mg/kg/h (decrease to 1 mg/kg/h if CrCl < 30 mL/min)

THROMBOLYSIS: ADJUVANT TREATMENT

ASA: 325 mg then 80 mg qd (long-term); ★ ISIS-2

CLOPIDOGREL: 300 mg (75 mg if > 75 years) then 75 mg qd (14 days to 1 year);
★ CLARITY-TIMI 28 and ★ COMMIT

ENOXAPARIN: ★ EXTRACT-TIMI 25 → **Enoxaparin superior to Unfractionated heparin** but ↗ major bleeding

- **Bolus**: 30 mg IV (< 75 years)
- **Maintenance**: 1 mg/kg SC bid (max 100 mg for first 2 doses) (if > 75 years: 0.75 mg/kg SC bid; max 75 mg for first 2 doses)
- **GFR < 30 mL/min**: 1 mg/kg SC once daily
- **Duration**: until discharge from hospital (or for one week or until revascularization)

FONDAPARINUX: 2.5 mg IV bolus then 2.5 mg SC once daily until discharge from hospital (or for one week or until revascularization); avoid if CrCl < 30 mL/min

- ★ **OASIS-6:** Fondaparinux vs Heparin; ↘ mortality; ↘ MI recurrence rate

UNFRACTIONATED HEPARIN: 60 IU/kg (max 4000 IU) then IV infusion for 48 h (or until revascularization) with target aPTT of 50-70 s (12 IU/kg/h; max 1000 IU/h)

EARLY PHARMACOINVASIVE STRATEGY: **immediate transfer post-thrombolysis** for coronary angiography ± revascularization within 3 to 24 h

- ★ **TRANSFER-AMI and ★ CARESS-in-AMI**: ↘ **recurrent ischemic events** +

RESCUE PCI: ★ REACT → ↘ recurrent MI; ↘ heart failure

- **Particularly beneficial if significant ischemic territory** (anterior MI; inferior infarction with RV involvement or with ST depression in V1-V3)

INTRACRANIAL HEMORRHAGE

a) Stop all agents potentially responsible
b) Brain imaging + Neurology / Neurosurgery consultation
c) 10 units of cryoprecipitate (fibrinogen and fVIII) + 2 units of FFP (fV and fVIII) + Protamine (1 mg for every 100 units of heparin over the last 4 hours) + Platelet transfusion (6-8 units)
d) ↘ Intracranial pressure (hyperventilation; Mannitol; head of bed to 30°; surgery)

2.6/ ACUTE CORONARY SYNDROME: ADJUVANT TREATMENTS

NITRATES: **venodilator** (↘ preload); **coronary vasodilator** (↗ perfusion); **arterial vasodilator** (↘ afterload)

- **Indications**: **A)** Ischemia / Recurrent angina; **B)** Significant HTN; **C)** Heart failure
- **Doses**: 0.4 mg sublingual every 5 min x 3 then IV infusion PRN (5-10 µg/min IV; increase by 10 µg/min every 5 min PRN up to a dose of 200 µg/min)
- **Contraindications**: SBP < 90 mmHg; HR < 50 bpm; HR > 100 bpm in the absence of heart failure; RV infarction; PDE-5 inhibitor (24 h for Sildenafil; 48 h for Tadalafil)

BETA-BLOCKERS: negative inotropic / negative chronotropic agent; ↘ O_2 demand

- ★ **MIAMI - ★ ISIS-1 - ★ COMMIT** → ↘ mortality; ↘ recurrent ischemic events; ↘ VF
- **Start orally within 24 h of presentation**
- **Contraindications**: Signs of heart failure; Low output state; Risk of cardiogenic shock (> 70 years; SBP < 120 mmHg; Sinus tachycardia > 110 bpm; HR < 60 bpm; Late presentation); PR > 0.24 s; 2nd or 3rd degree AV block; Active asthma
  - **Avoid BB with ISA**
  - **Short-acting BB:** IV Esmolol
  - **Verapamil or Diltiazem** as an alternative in the absence of contraindications and LV dysfunction

AGENT	INDICATION	DURATION	CAUTION
ASA	• All patients with ACS (★ Antithrombotic Trialists' Collaboration)	**Long term**	ASA allergy Peptic ulcer
Clopidogrel (75 mg qd)	• Post-ACS (without Ticagrelor or Prasugrel) (★CURE)	• 1 year if DES • Up to 1 year if BMS or medical treatment • BMS: minimum 2-4 weeks	Clopidogrel allergy
Ticagrelor (90 mg bid)	• Post-ACS (without Clopidogrel or Prasugrel) (★PLATO) • Consider > 1 year post MI in high-risk patients (★PEGASUS)	• 1 year if DES • Up to 1 year if BMS or medical treatment	Dyspnea Ventricular pauses
Prasugrel (10 mg qd)	• Post-ACS (without Clopidogrel or Ticagrelor) (★TRITON-TIMI 38)	• 1 year if DES • Up to 1 year if BMS	Avoid if weight < 60 kg or > 75 years or history of stroke - TIA
ACE inhibitor	• All patients with CAD (± HTN or DM or CRF) (★HOPE; ★EUROPA) • Post-ACS with LVEF < 40% or heart failure (★TRACE; ★SAVE; ★AIRE)	**Start within 24 h of presentation** **Long term**	ARF; Hyperkalemia; Cough; Angioedema Contraindicated if SBP < 100 mmHg
ARB (Valsartan or Candesartan)	• Intolerance of ACE inhibitors with LVEF < 40% or heart failure (★VALIANT; ★CHARM-Alternative)	Long term	ARF; Hyperkalemia; Hypotension
Beta-blockers	• All patients post-myocardial infarction (★ Freemantle meta-analysis) • Post-ACS with LVEF < 40% (★ CAPRICORN) • Residual coronary stenosis (anti-anginal)	• **Long term** if LV dysfunction or as antianginal • **Otherwise**: ≥ 3 years • **Target HR 50-60 bpm; use BB without ISA**	Active heart failure AV block Asthma
Statines	• All patients with ACS (★PROVE IT-TIMI 22)	• **Long term** • **High–dose statin**	Myopathy Myositis Transaminase
Eplerenone (25 mg then 50 mg qd)	• ACS with LVEF < 40% (with heart failure or DM) (★EPHESUS)	Long term	Hyperkalemia > 5 mmol/L GFR < 30 mL/min
TNT (Nitropuff)	• All patients with coronary disease	Long term	Avoid if hypotension or PDE-5 inhibitor
Warfarin	• LV thrombus • Significant LV dysfunction with extensive regional wall motion abnormalities or LV aneurysm (class IIb recommendation)	**3 months then reevaluate** Long term if mobile / pedunculated thrombus	**Target INR 2-2.5** in the presence of dual antiplatelet therapy Add PPI

GLYCEMIC CONTROL: target blood glucose **< 10 mmol/L (180 mg/dL)** (★DIGAMI); avoid hypoglycemia (★NICE-SUGAR) +

PPI (PREFER PANTOPRAZOLE): patient on dual antiplatelet therapy with ≥ 1 risk factor:
A) History of upper GI bleeding / ulcer; **B)** > 60 years; **C)** Anticoagulant or Corticosteroids or NSAID; **D)** *H. pylori* - positive

ANEMIA: target hemoglobin > 70-80 g/L +

AVOID NSAID

› **If unavoidable** (despite Acetaminophen; ASA; Narcotics) → **prefer nonselective NSAID** (Naproxen; Ibuprofen) +

AVOID HORMONE THERAPY

STRESS TEST BEFORE DISCHARGE FROM HOSPITAL

› No angina / Heart failure / Arrhythmia for 48-72 h
› **Submaximal stress test (3-5 days)**: stop if HR ≥ 120 bpm or ≥ 70% of predicted HRmax or ≥ 5 METs or Angina or Dyspnea or ↘ ST 2 mm or Hypotension or ≥ 3 consecutive PVCs
› **Stress test limited by symptoms (3 weeks):** not guided by HR or METs

MANAGEMENT ON DISCHARGE FROM HOSPITAL

MANAGEMENT OF RISK FACTORS: ▸▸| Chapter 9

ADMISSION TO CARDIAC REHABILITATION CENTER

SMOKING CESSATION

CONTROL OF LIPIDS

› **Lipid profile** on day 1 of ACS (↘ TC and ↘ HDL within 24-48 h of ACS)
› **Target**: High-dose statin; **target ↘ > 50% LDL** +

BP CONTROL: < 140/90 mmHg (< 140/85 mmHg in the presence of DM) +

DM CONTROL: **HbA1c < 7 %** +

WEIGHT: **BMI: 18.5-24.9 kg/m2; waist < 102 cm (M) and < 88 cm (F)** +

BALANCED DIET

PHYSICAL ACTIVITY: **30 minutes of moderate exercise (rapid walking) 5 times a week** +

› Pre-training stress test if necessary depending on risk factors

INFLUENZA VACCINE annually

TREAT DEPRESSION post-IM

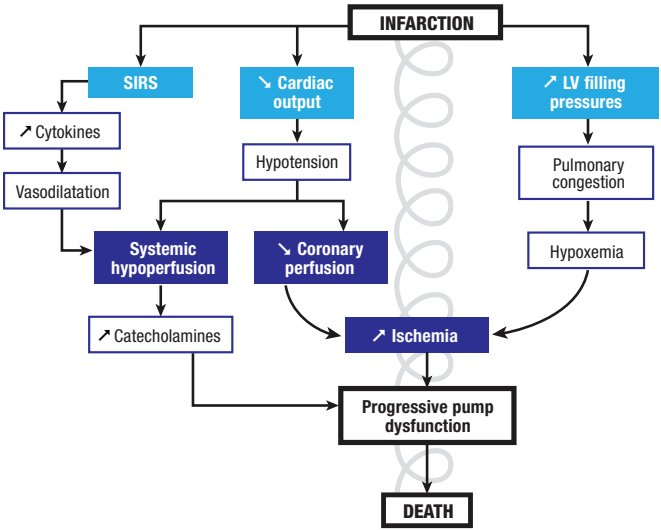
SICK LEAVE: determined case by case; 2 weeks to 10 weeks

SEXUAL ACTIVITY: resume after 7-10 days (equivalent to one flight of stairs)

PLANE TRAVEL: ▸▸| Chapter 9

2.7/ COMPLICATIONS OF MYOCARDIAL INFARCTION

CARDIOGENIC SHOCK



↘ Cardiac output with inadequate tissue perfusion (despite sufficient filling pressures)

HEMODYNAMIC PARAMETERS

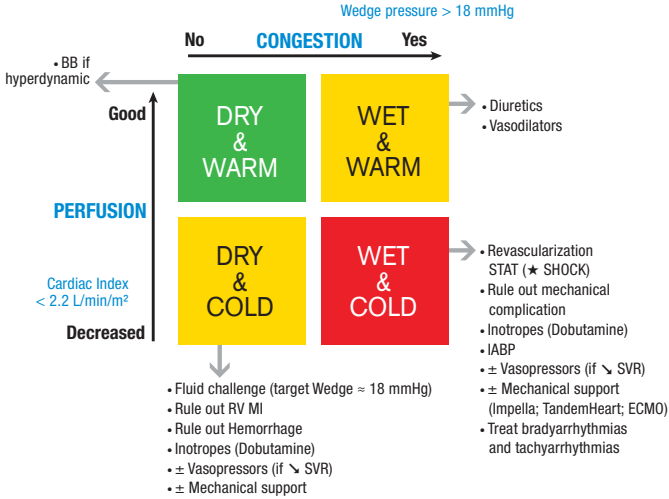
- Hypotension (SBP < 90 mmHg)
- Systemic hypoperfusion (cold extremities; altered level of consciousness; ↘ urinary output; SVO_2 < 70 %)
- ↘ Cardiac Index (< 2.2 L/min/m²)
- ↗ Filling pressures (Wedge pressure > 18 mmHg)

ETIOLOGIES: **Extensive infarction; Mechanical complication; RV infarction**

- **DDx:** Hemorrhage; Pulmonary embolism; Tamponade; Sepsis; Myocarditis; Takotsubo; HCM; Endocarditis; Aortic dissection

MANAGEMENT

- ★ **SHOCK:** **↘ mortality with early revascularization (< 75 years)**

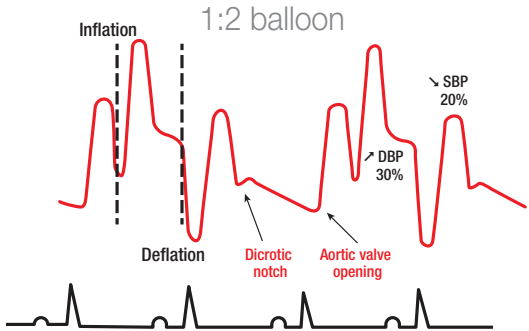


INTRA-AORTIC BALLOON PUMP

INDICATIONS: A) Cardiogenic shock; **B)** Refractory ischemia; **C)** Mechanical complication of MI; **D)** Support during a procedure at high risk of hemodynamic instability

MECHANISM: Inflation in diastole immediately after closure of the aortic valve (↗ **coronary perfusion);** deflation at systole just before opening of the aortic valve **(suction effect; ↘ afterload)**

- Increases cardiac output ≈ **10-15 %**
- Monitored by ECG and BP monitor
- ★ IABP-SHOCK II study: no benefit



CXR POSITION: tip of the catheter **at the level of the carina** (> 4 cm below the aortic knob) +

CONTRAINDICATIONS: Moderate to severe AR; Aortic dissection; Significant abdominal aortic aneurysm; severe PAD; Uncontrolled sepsis

COMPLICATIONS: Aortic lesion / perforation; Bleeding at site of introduction; Ischemia distal to introducer (target the common femoral artery during introduction); Thrombocytopenia; Hemolysis; Atheroembolism; Renal ischemia; Cerebral ischemia in the case of proximal migration of the balloon; Infection

RIGHT VENTRICULAR INFARCTION

RV very resistant to ischemia (thin myocardium)

› **Excellent recovery of RV function post-MI**

CLINICAL FEATURES: Shock; ↗ CVP (↗ Y descent; mimics constrictive pericarditis); Kussmaul sign; Pulsus paradoxus; Clear lungs

HEMODYNAMIC PARAMETERS: Hypotension; ↗ RA pressure / ↗ RVEDP; ↘ RV systolic pressure; ↘ Wedge pressure; ↘ Cardiac index

ECG: **ST elevation > 0.5-1 mm V3R and/or V4R** (in the context of infarction of the inferior wall of the LV); ± ST elevation in V1-V2 +

DDX: Pulmonary embolism **(absence of RWMA in inferior wall of LV)** +

COMPLICATIONS: R → L shunt (via PFO); Shock; Pulmonary embolism; Arrhythmia; AV block; Death

MANAGEMENT: **1)** Avoid TNT; **2)** Reperfusion; **3)** Bolus of normal saline to maintain adequate RV preload (attention to interdependence with LV; **avoid RVEDP > 15 mmHg)**; **4)** Target Wedge pressure 15-18 mmHg; **5)** Inotropes (Dobutamine); **6)** Decrease RV afterload (avoid hypoxia; minimize PEEP; NO); **7)** Maintain AV synchrony (to ensure good filling of the ischemic RV and to increase RV output); **8)** IABP; RVAD; Impella; Creation of an ASD when necessary +

LEFT VENTRICULAR FREE WALL RUPTURE

One to 14 days post-transmural infarction

› **Secondary to extension of the infarction**: thinning and dilatation of the necrotic zone
› Often anterior or lateral LV wall

PRESENTATION: Pleuritic pain; Hypotension; Shock; Sudden death (pulseless electrical activity)

CLINICAL FEATURES: JVD; Pulsus paradoxus; Shock

TTE: signs of tamponade; look for the site of rupture

LEFT VENTRICULAR PSEUDOANEURYSM

Ventricular rupture contained by the pericardium and by thrombus / organized hematoma

Narrow neck (<< diameter of the pseudoaneurysm)

High risk of rupture and hemopericardium

LEFT VENTRICULAR ANEURYSM

Thinning of myocardium (but no rupture, in contrast with pseudoaneurysm)

Dyskinesia with paradoxical systolic expansion (alters the geometry and efficacy of contraction; ↗ wall stress)

Large neck (≥ 0.5 x diameter of the aneurysm)

Low risk of rupture

ECG: persistent ST elevation

COMPLICATIONS: Embolism; Arrhythmia; Heart failure; Angina

INTRAVENTRICULAR THROMBUS

↗ RISK OF EMBOLIZATION: Mobile; Protrusion into the ventricle; Visualized on several sections; Contiguous zones of akinesia and hyperkinesia

MANAGEMENT: Anticoagulant therapy for 3-6 months then re-evaluate

VENTRICULAR SEPTAL RUPTURE

SITE

- **Anterior infarction** → apical interventricular septum
- **Inferior infarction** → inferobasal interventricular septum (less favorable prognosis)

PRESENTATION: Hypotension - Shock; Acute pulmonary edema; R and L heart failure; Blocks

CLINICAL FEATURES: Shock; **Prominent holosystolic murmur ± thrill; S3;** Pulmonary edema; Signs of right heart failure

TTE: L→R shunt; RV insufficiency

CARDIAC CATHETERIZATION: O_2 step-up between RA and RV; Prominent V wave +

TREATMENT: Nitroprusside; IABP; Inotropes; Surgery vs percutaneous closure

PAPILLARY MUSCLE RUPTURE

Posteromedial papillary muscle (inferior infarction; supplied by PDA) >> anterolateral papillary muscle (double blood supply by LAD and circumflex) +

PRESENTATION: Hypotension; Shock; Acute pulmonary edema; **Systolic murmur, often minor** (early systolic equalization of transvalvular pressures) +

TTE (± TEE): Rupture of a papillary muscle or chorda tendineae; Leaflet eversion; Severe MR on Doppler; Hyperdynamic LV; PHT

CARDIAC CATHETERIZATION: Prominent V wave; ↗ PAP (± contaminated by V wave) +

TREATMENT: Nitroprusside; IABP; Inotropes; Mechanical ventilation; Urgent surgery

PERICARDITIS

EARLY: pericardial extension of transmural MI

- **Presentation:** Pleuritic pain radiating to the trapezius; **Pericardial friction rub**; **Localized ECG changes** +
- **Management:** Caution with anticoagulants (risk of hemorrhagic pericarditis; monitor by TTE); ASA 650 mg PO every 4-6 h; Colchicine

LATE (> 7 DAYS): Dressler's syndrome; Immune phenomenon

ARRHYTHMIAS AND BLOCKS

PVC: BB; Correct electrolyte disorders; No benefit of AAD (★ CAST; ★ SWORD)

MONOMORPHIC VT: Correct electrolyte disorders; BB; AAD; ECV; **ICD if > 48 h (probable permanent arrhythmogenic substrate)**

POLYMORPHIC VT: **Rule out ischemia**; Rule out ↗ QT; BB; Correct electrolyte disorders

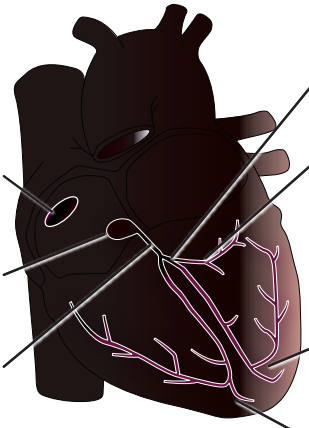
VF: Rule out ischemia; BB; AAD (Lidocaine; Amiodarone); ICD if > 48 h

AIVR: Ventricular rhythm 60-100 bpm; **Specific marker of reperfusion; Observation**; ↗ Sinus rhythm PRN (Atropine; Atrial pacing)

SINUS BRADYCARDIA: often associated with inferior STEMI (**Bezold-Jarish reflex**); Atropine; Atrial pacing

AV BLOCK AND INTRAVENTRICULAR BLOCKS

INFERIOR INFARCTION	ANTEROSEPTAL INFARCTION
RCA 90%; Circumflex 10%	**Proximal LAD (± septal branches)**
• Mechanism: ↗ **Vagal tone** (< 6h; Bezold-Jarish) and/or **AV node ischemia**	• Mechanism: **Extensive necrosis of the septum and conduction tissue** (His-Purkinje system)
Bradyarrhythmias • Sinus bradycardia • **Intranodal** AV block 1st degree AV block or 2nd degree Mobitz I AV block or sometimes 3rd degree intranodal AV block	**Bradyarrhythmias** • **Infranodal** AV block 2nd degree Mobitz II AV block or 3rd degree infranodal AV block • ↗ PR secondary to slowing of His-Purkinje conduction
• Progressive onset of AV block	• Sudden onset of AV block (< 24 h); often preceded by RBBB ± LAHB
• **Jonctional escape rhythm** (His); narrow QRS; 40-60 bpm	• **Escape rhythm distal to His bundle** • Wide QRS; unstable; risk of asystole
• **Often benign and transient (5-7 days)**	• **Often associated with extensive infarction**
• Atropine within the first 24 h (vagal hypertonia) • Permanent pacemaker rarely indicated (reversible conduction disorder)	**Temporary pacemaker** • 2nd degree Mobitz II or 3rd degree AV block • Alternating RBBB with LBBB • Acute bifascicular block or *de novo* LBBB • RBBB with ↗ PR **Permanent pacemaker** • 2nd degree intra- or infrahisian AV block with alternating branch block • 3rd degree intra- or infrahisian AV block • Persistent 2nd or 3rd degree AV block with symptoms • High-grade transient infranodal 2nd degree or 3rd degree AV block with associated branch block (except for isolated left anterior hemiblock)



2.8/ REVASCULARIZATION - PCI

SIGNIFICANT STENOSIS

ANGIOGRAPHIC	HEMODYNAMIC	IVUS (INTRAVASCULAR ULTRASOUND)
≥ 70% (LMCA: ≥ 50%)	FFR ≤ 0.80	• LMCA: Area < 6 mm² (6 to 7.5 mm² → determine FFR) • Other vessels: Area < 4 mm²

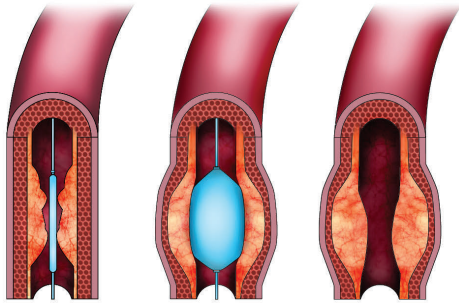
TECHNIQUES

BALLOON ANGIOPLASTY (PTCA): **stretches / tears / redistributes the atherosclerotic plaque in order to enlarge the coronary lumen;** risk of dissection or abrupt closure; risk of restenosis

STENT: treats the dissection associated with PTCA and ↘ the risk of abrupt closure; ↘ risk urgent CABG; ↘ restenosis

- **One-year clinical restenosis rate**: **PTCA 30%; BMS 10-15%; DES 3-5%**
  - **Clinical restenosis**: during the **first 6-9 months** post-PCI
- **DES**: ↘ restenosis and ↘ reintervention; ↗ very late stent thrombosis (> 1 year) (risk markedly decreased with new generation DES)
  - **New generation DES:** thin-strut platform; limus-based antiprolferative drug; polymer with improved biocompatibility; improved safety compared to early-generation DES; should be considered by default in all clinical conditions and lesion subsets

BALLOON ANGIOPLASTY



PREFER DES	CONSIDER BMS
• LMCA • Small vessels (< 2.5 mm diameter) • Long lesion (> 20 mm) • DM • In-stent restenosis • Bifurcation • Vein graft • Chronic total occlusion	• Dual antiplatelet therapy for 3-6 months impossible • Probable surgery < 6 months • Bleeding risk • Anticoagulation (Warfarin or DOAC) required

FFR (Fractional flow reserve): **to determine whether an intermediate stenosis (50-70%) is hemodynamically significant**

› **Quantify the trans-stenotic pressure gradient**

› ★ **FAME**: angioplasty guided by fractional flow reserve (FFR) determination **associated with improvement of primary outcome** (death; MI; reintervention)

IVUS (Intravascular ultrasound): **A)** Determines the severity of a stenosis on the LMCA; **B)** Determines the mechanism of stent restenosis or thrombosis; **C)** Guidance during complex PCI; **D)** Follow-up of cardiac allograft vasculopathy

MANUAL ASPIRATION THROMBECTOMY: aspiration of intra-coronary thrombus; ↘ distal embolism (no benefit in ★ TASTE and ★ TOTAL)

ROTATIONAL ATHERECTOMY: Grinding of calcified atherosclerotic plaque; facilitates passage and deployment of the balloon and stent; risk of coronary perforation

SPECIFIC LESIONS

IN-STENT RESTENOSIS: DES implantation or drug-coated balloons; intracoronary imaging

CHRONIC TOTAL OCCLUSION (CTO): revascularization in the presence of significant viability and a significant ischemic territory

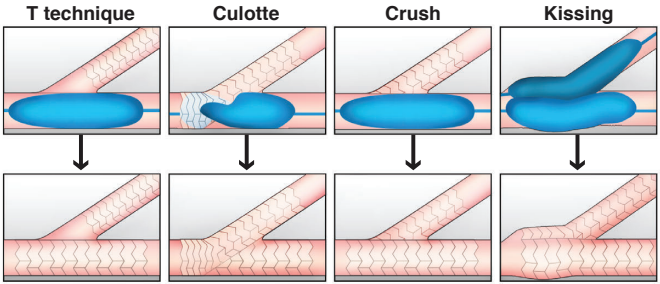
› **Percutaneous revascularization**: complex technique via an anterograde approach (± subintimal dissection and re-entry) and/or retrograde approach (via collateral pathways)

PCI ON VEIN GRAFT: ↗ risk of periprocedural MI and no-reflow (atheroembolism); use an embolic protection device

BIFURCATION: 2 strategies

a) PCI with stent in the main vessel only (angioplasty and/or stent in the branch if necessary) (★ Nordic-Baltic Study IV and ★ TRYTON)

b) PCI with stenting of both vessels (especially if complex bifurcation with large branch and significant risk of occlusion); terminate the operation with simultaneous inflation of a balloon in each vessel ("kissing")



LEFT MAIN CORONARY ARTERY: percutaneous revascularization possible if low risk of procedural complications (proximal LMCA; SYNTAX ≤ 32) or high surgical risk

COMPLICATIONS OF PCI

RISK OF COMPLICATIONS DURING PCI ACCORDING TO THE TYPE OF LESION

TYPE I: Low risk	1. Patent Lesion 2. Does not meet the criteria for a type C lesion
TYPE II	1. Patent Lesion 2. Meets one of the criteria of a type C lesion › Diffuse lesion (> 20 mm long) › Severe proximal tortuosities › Extreme angle (> 90°) › Impossible to protect a major branch › Vein graft with friable lesions
TYPE III	• Occluded lesion • Does not meet the criteria for a type C lesion
TYPE IV: High risk	• Occluded lesion • Meets one of the criteria of a type C lesion

COMPLICATIONS: Death (0.7% elective PCI); MI; Stroke (0.2%); TIA; Vascular access site complication; Coronary perforation (± tamponade); Coronary dissection (abrupt closure); No-reflow (↘ anterograde flow in the absence of epicardial stenosis secondary to distal microembolism / vasospasm / endothelial dysfunction; management with Adenosine or intracoronary Verapamil or GPIIb/IIIa inhibitors); Branch occlusion; Urgent CABG (0.4%); ARF; Hemorrhage

› **Femoral or radial access complications**: ▶▶| Chapter 1 - Coronary angiography

› **Post-coronary angiography ARF**: ▶▶| Chapter 1 - Coronary angiography

EARLY CHEST PAIN POST-PCI: Stent thrombosis; Residual dissection / Abrupt closure; No reflow; Distal embolism; Branch occlusion

STENT THROMBOSIS: 1% at 1 year; Mortality 20-45%

- **BMS**: **during first 30 days** (rare after 30 days due to complete neo-endothelialization)
- **DES**: **can occur after 1 year** (very late thrombosis due to incomplete neo-endothelialization); decreased risk with new generation DES
- **Risk factors:** acute myocardial infarction; Nonadherence with P2Y12 inhibitor; Resistance to Clopidogrel; DM; Long segment; Small vessels (diameter < 2.5 mm); Bifurcation; Incomplete stent apposition; Dissection at the stent margin; Overlapping stents
- **Treatment:** emergency PCI; Prasugrel or Ticagrelor; IVUS or OCT to detect mechanical problems

ADJUVANT TREATMENT - ELECTIVE PCI

▶▶| Chapter 1 - Coronary angiography

ASA: 325 mg then 80 mg qd (long term)

CLOPIDOGREL: 600 mg loading dose for elective stenting (★ ARMYDA-2) **then 75 mg qd**

- **BMS with bleeding risk**: Clopidogrel for a **minimum of 2-4 weeks**
- **DES**: dual antiplatelet therapy for a minimum of **6 months** (★ ISAR-SAFE)
  - Strict minimum of 3-6 months with new generation DES
  - ★ **DAPT**: 30 months of DAPT (vs 12 months) associated with ↘ stent thrombosis and MACCE but ↗ moderate or severe bleeding
  - **Prolonged dual antiplatelet therapy**: consider in the presence of a high risk of stent thrombosis (according to anatomy / procedure) or if late stent thrombosis would have major consequences (LMCA; bifurcation; ostium...)

GPIIB/IIIA INHIBITORS: at the interventional cardiologist's discretion

UNFRACTIONATED HEPARIN: **A)** Procedure without GPIIb/IIIa inhibitors: 70-100 U/kg targeting ACT 250-300 s (HemoTec) or 300-350 s (Hemochron); **B)** Procedure with GPIIb/IIIa inhibitors: 50-70 IU/kg targeting ACT 200-250 s

STATIN PRE-PCI ↘ risk of periprocedural MI (★ ARMYDA; ★ NAPLES II)

2.9/ REVASCULARIZATION - SURGERY

ASSESSMENT OF PERIOPERATIVE RISK

STS SCORE: in-hospital or 30-day mortality, and in-hospital morbidity / http://riskcalc.sts.org

EUROSCORE II: in-hospital mortality / www.euroscore.org

ADJUVANT TREATMENT

ASA: for all patients (to protect graft patency)

P2Y12 INHIBITORS: Stop Clopidogrel and Ticagrelor > 5 days pre-op; Stop Prasugrel > 7 days preop

GPIIB/IIIA INHIBITORS: Stop Eptifibatide / Tirofiban 2-4 h pre-op; Stop Abciximab > 12 h pre-op

STATIN: for all patients

ACE INHIBITORS: for all patients (start postoperatively when hemodynamic stability is achieved)

BB: **> 24h pre-op** (in the absence of contraindication) to prevent perioperative AF (continue post-op)

GLYCEMIC CONTROL: target perioperative blood glucose **< 10 mmol/L**

ASSESSMENT OF CAROTID ARTERIES

CAROTID DOPPLER IN HIGH-RISK PATIENTS: > 65 years; LMCA; PAD; History of TIA - stroke; HTN; Smoking; DM

INDICATIONS FOR PRE-CABG REVASCULARIZATION (angioplasty / stent or endarterectomy)

a) History of TIA or stroke with 50-99% stenosis (class IIa recommendation)
b) Severe bilateral stenoses (70-99%) or severe unilateral stenosis (70-99%) with contralateral occlusion (class IIb recommendation)
- › Note: diverging indications according to the various guidelines
- › Assessment on an individual basis by a multidisciplinary team including a neurologist

COMPLICATIONS

COMPLICATIONS: Death; Stroke (micro- or macroembolism; hypoperfusion); Cardiogenic shock; Tamponade (often localized over the RA); post-CPB cognitive deficits; ARF; post-CPB SIRS; Hemorrhage; Re-exploration; Prolonged mechanical ventilation; Sternal osteomyelitis / Mediastinitis; Perioperative myocardial infarction; AF; Pulmonary complications (ARDS; Pneumonia; Atelectasis; Phrenic nerve palsy); Intestinal ischemia

MEDIASTINITIS / STERNAL INFECTION

- › **Risk factors**: DM; Obesity; COPD; Prolonged CPB; REDO; Prolonged intubation; Repeat surgical exploration
- › **Management:** Antibiotics; Surgical debridement; Reconstruction (pectoralis muscle flap); VAC; Sternal plate

VEIN GRAFT: Early occlusion rate (before discharge from hospital): 10%; 1-year occlusion rate: 25%; **10-year occlusion rate: 50%** +

- › **Arterial bypass graft**: **10-year patency rate > 90%** +

POSTOPERATIVE ATRIAL FIBRILLATION

0-5 days post-op; Frequently resolves spontaneously in 6-12 weeks

PROPHYLAXIS: BB (1st choice); Amiodarone if BB contraindicated (400 mg PO bid x 6 days preop and 6 days post-op) +

- › **Other options**: Sotalol; IV magnesium (1.5 g IV daily for 4 days post-op); Atrial overdrive; Colchicine (★ COPPS-POAF)

MANAGEMENT: rate control or rhythm control according to symptoms; anticoagulation if **AF > 48 h**; review treatment at 12 weeks +

MINIMALLY INVASIVE SURGERY

BEATING HEART (OFF-PUMP): requires sternotomy with cardiac stabilization device; theoretically avoids the disadvantages of CPB and clamping of the ascending aorta

- › **No demonstrated benefit** to date (★ ROOBY, ★ GOPCABE, ★ CORONARY)

MIDCAB: left anterior mini-thoracotomy; beating heart internal mammary artery bypass graft to LAD; ventilation of only one lung

- › **Hybrid procedure:** LIMA to LAD; PCI of other vessels; avoids sternotomy and clamping of the aorta

ROBOTIC TOTAL ENDOSCOPIC BYPASS GRAFT: with femoro-femoral CPB

2.10/ PRINZMETAL ANGINA (VASOSPASTIC ANGINA)

Severe angina at rest with transient ST elevation

- Worse between midnight and 8:00 am
- **Risk factors**: Smoking; Migraine; Raynaud; 5-fluorouracil; Cyclophosphamide; Hyperventilation; Cold

COMPLICATIONS: MI; VT; VF; AV block; Asystole; Sudden death

STRESS TEST: 1/3 negative; 1/3 with ST elevation; 1/3 with ST depression

CORONARY ANGIOGRAPHY: Coronary spasm; RCA > LAD; Multiple spontaneous spasms on multiples vessels possible

- **Provocation test rarely performed**
  - **Ergonovine provocation test**: 0.05 to 0.2 mg IV
  - **Acetylcholine provocation test**: 10-25-50-100 µg intracoronary; focal spasm during Prinzmetal angina

MANAGEMENT: Smoking cessation; CCB (combination of dihydropyridine and nondihydropyridine PRN); Nitrates; Prazosin (alpha-blocking agent) and Nicorandil if necessary; Avoid nonselective BB (risk of unopposed alpha stimulation); Avoid ASA (inhibits prostacyclin synthesis); PCI if associated stenosis; Mg^{2+} supplement; Statins may be beneficial; Defibrillator for secondary prevention (especially if ischemia persists despite treatment)

2.11/ CARDIAC SYNDROME X

More or less typical retrosternal chest pain with ischemia documented on noninvasive test (ST depression and/or perfusion abnormality) in the absence of any significant epicardial CAD

Associated with increased CARDIOVASCULAR RISK

MECHANISM: **probable microvascular endothelial dysfunction with decreased vasodilatation reserve;** ± hypersensitivity to pain

- **40-50% of the resistance to coronary flow is derived from the microvasculature**; an insufficient vasodilatation reserve decreases coronary perfusion on exertion

MANAGEMENT: ACE inhibitors and Statins (improve endothelial dysfunction); Nitrates; BB; CCB; Treatment of risk factors; Regular exercise

- **Persistent retrosternal chest pain**: Nicorandil; Imipramine or Amitriptyline; Aminophylline; Neurostimulation (spinal cord); External counterpulsation; Psycho-intervention...

Heart failure 03

3.1/	Heart failure: assessment	112
3.2/	Systolic heart failure: management	115
3.3/	Diastolic heart failure (preserved LVEF)	123
3.4/	Decompensated heart failure	125
3.5/	Heart transplantation	130
3.6/	Long-term ventricular assist device	133
3.7/	Right heart failure	136
3.8/	Palliative care	136

3.1/ HEART FAILURE: ASSESSMENT

DEFINITION: Complex clinical syndrome secondary to a functional or structural abnormality of the heart which impairs the capacity of the ventricle to eject blood (and perfuse tissues) or to be adequately filled

› **This clinical syndrome leads to typical symptoms and signs**

SYSTOLIC HEART FAILURE	HEART FAILURE WITH PRESERVED LVEF
1. Typical symptoms **2. Typical signs** **3. ↘ LVEF**	1. Typical symptoms 2. Typical signs 3. Normal or slightly decreased LVEF; non-dilated LV 4. Structural heart disease (LVH; LAH) and/or diastolic dysfunction

LVEF = stroke volume (end-diastolic volume – end-systolic volume) / end-diastolic volume

› **When LVEF is decreased: stroke volume is maintained by increasing end-diastolic volume** (eccentric LVH)

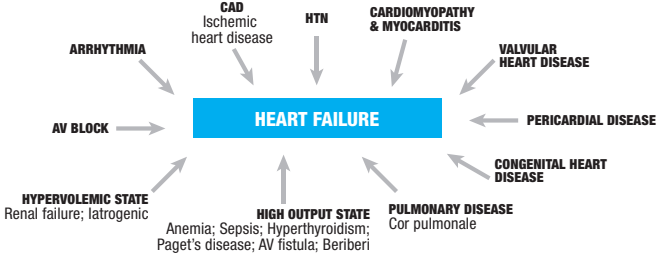
SYMPTOMS	SIGNS
• Dyspnea • **Orthopnea** • **PND** (1-2 h after going to bed; resolution in 15-30 min) • **↘ Exercise tolerance** • Tiredness • Lower limb edema • **Peripheral edema** • **Nocturnal cough** • Wheezing • Weight gain • Loss of appetite • RUQ pain • Nocturia	• Cachexia • Hypotension; OH; Narrow pulse pressure • Pulsus alternans; ↘ Pulse amplitude • **Tachycardia** • Tachypnea • Cheyne-Stokes breathing • **JVD** ; HJ reflux • Lateralized and widened apex • Left parasternal heave / Signs of PHT • Decreased S1 • **S3** - S4 (± palpable) • AV valve regurgitation • **Crackles** • Wheezing • **Signs of pleural effusion** • **Hepatomegaly (± pulsatile)** • **Peripheral edema** (leg edema; scrotum; presacral; ascites) • Cold extremities • Confusion / Decreased level of consciousness

NYHA FUNCTIONAL CLASS

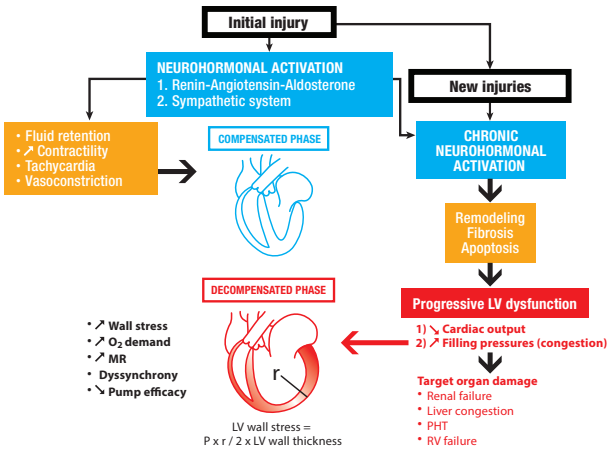
NYHA I	No limitation in ordinary physical activity (no tiredness, dyspnea or palpitations)	**≥ 7 METs** • Climbing one flight of stairs with a bag of groceries • Shoveling snow • Bicycling; Skiing; Jogging/walking (8 kph)

NYHA II	Slight limitation during physical activity; ordinary physical activity causes symptoms (tiredness, dyspnea, palpitations)	**5-7 METs** • Climbing one flight of stairs without stopping • Walking briskly on level ground (6.5 kph) • Gardening; Dancing
NYHA III	Marked limitation during physical activity; comfortable at rest; less than ordinary activity causes symptoms (tiredness, dyspnea, palpitations)	**2-5 METs** • Showering without a break • Getting dressed without a break • Walking briskly on level ground (4 kph) • Making a bed • Bowling; Golf
NYHA IV	Inability to carry on any physical activity without discomfort ± symptoms at rest	**< 2 METs** • Unable to perform the activities of NYHA III

ETIOLOGIES



PATHOPHYSIOLOGY



ASSESSMENT

WORK-UP: CBC; Electrolytes (including Ca^{2+}/Mg^{2+}); Creatinine - BUN; LFTs; Blood glucose; HbA1c; TSH; Urinalysis; Lipids

› **If necessary**: CK; Iron assessment; HIV; ANA; RF; Urine metanephrines; SPEP - UPEP; Uric acid; CRP; Troponin; Polysomnography

ECG: Sinus tachycardia; arrhythmia (AF; PVCs; NSVT); Conduction disorder / LBBB; LVH; LAH; Q waves; ischemia; low voltage QRS

› **AV block**: Drug-induced; myocardial infarction; myocarditis; sarcoidosis; familial cardiomyopathy (LMNA; SCN5A); Lyme disease

CXR: prominent hila; Kerley B lines (fine horizontal linear opacities extending to the pleura); peribronchial edema; interstitial / alveolar edema; redistribution to apices; pleural effusion; fluid in the fissure; cardiomegaly; other cause of dyspnea

TTE (± CONTRAST): chamber dimensions; LVH; systolic and diastolic function; LVEF (Simpson); valves; PAP; thrombus; cardiac output (LVOT VTI)

RADIONUCLIDE VENTRICULOGRAPHY: LVEF; RVEF

CARDIAC MRI: cardiac structure and function; LVEF; tissue characterization; evaluation of cardiomyopathy / myocarditis

CORONARY ANGIOGRAPHY (± FFR): rule out significant CAD

› **Noninvasive evaluation** (MIBI-P; stress echocardiography; coronary CT angiography) possible if few risk factors / low pre-test probability / low impact of the result on management

STRESS TEST / 6MWT / VO_2MAX: **A)** Objective evaluation of functional class; **B)** Rule out ischemia; **C)** Pre-transplant (VO_2max); **D)** Prescription of exercise; **E)** Prognosis; **F)** Distinguish cardiac from pulmonary cause

› **VO_2max < 12 mL O_2/kg/min** associated with poorer survival than in patients with a heart transplant +

› **6MWT**: normal > 600 m; < 350 m roughly equivalent to NYHA III

BIOPSY: ▸▸| Chapter 5

BNP: released by the failing heart or in response to hemodynamic stress; reflects wall stress and filling pressures

› Increases with age; decreases with obesity

› **DDx ↗**: CRF; arrhythmia; ACS; pulmonary embolism; severe COPD / PHT; sepsis; cirrhosis

› **Indications**: **A)** Identify the cause of dyspnea (cardiac versus non-cardiac); **B)** Prognosis

- BNP-guided management of heart failure remains controversial; studies report divergent results

ACUTE HEART FAILURE UNLIKELY	NT-proBNP < 300 pg/mL (NPV 98 %)	BNP < 100 pg/mL
PROBABLE ACUTE HEART FAILURE	NT-proBNP > 450 pg/mL (< 50 years) > 900 pg/mL (50-75 years) > 1800 pg/mL (> 75 years)	BNP > 500 pg/mL

› **Variation**: a change of > 30% in BNP level should call for more intesive follow-up / treatment

PROGNOSIS

SEATTLE HEART FAILURE MODEL: http://depts.washington.edu/shfm

HEART FAILURE SURVIVAL SCORE

PROGNOSTIC FACTORS: Demographics; Etiology; Comorbidities; NYHA; Hemodynamics (LVEF; PAP; Wedge; Cardiac index; Transpulmonary gradient); Exercise stress test (BP; 6MWT; VO_2max; Anaerobic threshold; Ve/VCO_2 slope > 35); Anemia; Hyponatremia; QRS duration; BNP; Troponin...

3.2/ SYSTOLIC HEART FAILURE: MANAGEMENT

OBJECTIVES

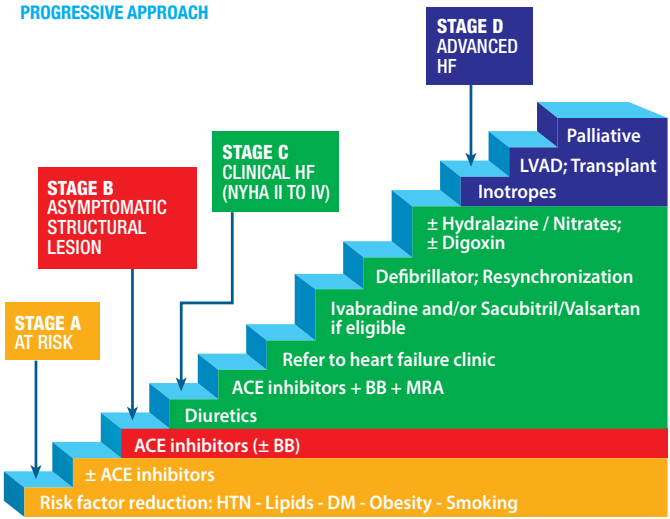
QUALITY OF LIFE

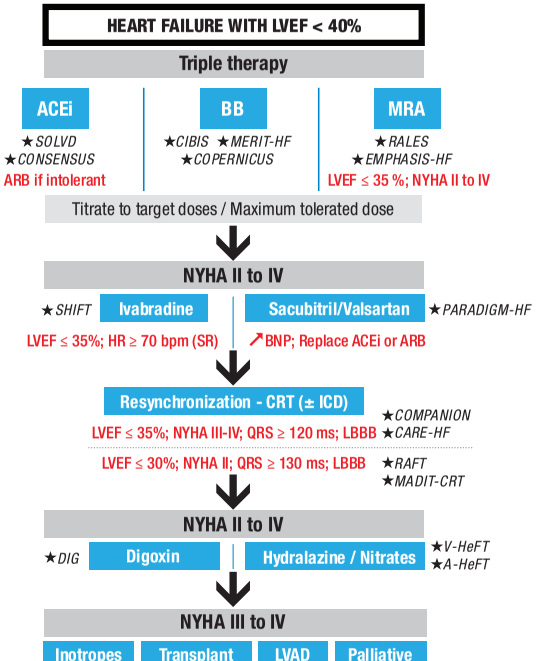
- ↓ Symptoms
- ↓ Hospitalizations
- Improve functional class
- Prevent disease progression

QUANTITY OF LIFE

- ↑ Survival

PROGRESSIVE APPROACH





HEART FAILURE WITH LVEF < 40%
Triple therapy
ACEi
★SOLVD
★CONSENSUS
ARB if intolerant

	INITIAL DOSE (mg)	TARGET DOSE (mg) (to be reached whenever possible)
ACE INHIBITORS - ANGIOTENSIN-CONVERTING ENZYME INHIBITORS		
Captopril	6.25 tid	50 tid
Enalapril	1.25 bid	10-20 bid
Lisinopril	2.5 qd	20-40 qd
Ramipril	1.25 bid	5 bid
Perindopril	2.5 qd (2 qd in Canada)	10 qd (8 qd in Canada)
Trandolapril	0.5 qd	4 qd
BB - BETA-BLOCKERS		
Bisoprolol	1.25 qd	10 qd
Carvedilol	3.125 bid	25-50 bid
Metoprolol succinate XL	12.5-25 qd	200 qd
ARB - ANGIOTENSIN RECEPTOR BLOCKERS		
Candesartan	4 qd	32 qd
Valsartan	20-40 bid	160 bid
NEPRILYSIN INHIBITOR		
Sacubitril / Valsartan	50 (24/26) - 100 (49/51) mg bid	200 (97/103) mg bid
I_F CHANNEL INHIBITOR		
Ivabradine	5 bid	7.5 bid
LOOP DIURETICS		
Furosemide	20-40 qd or bid (adjusted to renal function)	max 600 /24h
Bumetanide	0.5-1 qd or bid	max 10 /24h
MRA - MINERALOCORTICOID RECEPTOR ANTAGONISTS		
Spironolactone or Eplerenone	**Eplerenone** CrCl > **50 mL/min**: 25 mg qd; CrCl **30-49 mL/min**: 25 mg every 2 days **Spironolactone** CrCl > **50 mL/min**: 12.5 to 25 mg qd; CrCl **30-49 mL/min**: 12.5 mg qd or every 2 days	**Eplerenone** CrCl > **50 mL/min**: 50 mg qd; CrCl **30-49 mL/min**: 25 mg qd **Spironolactone** CrCl > 50 mL/min: 25 mg qd or bid; CrCl 30-49 mL/min: 12.5 to 25 mg qd
THIAZIDE DIURETICS		
Hydrochlorothiazide	25 qd ou bid	max 200 /24h
Metolazone	2.5-5 qd	max 20 /24h
Indapamide	2.5 qd	max 5 /24h
DIGOXIN		
Digoxin	0.125 **Adjusted to renal function** Total loading dose of 1 mg PO per 24 h in 4 doses divided on the 1st day when rapid effect is required; adjusted to renal function	Plasma target: **0.5 to 0.9 ng/mL** (1 week after titration)
HYDRALAZINE / NITRATES		
Hydralazine / Nitrates	Hydralazine: 10-25 tid Isosorbide dinitrate: 10 tid	Hydralazine: 75 tid Isosorbide dinitrate: 40 tid

ANGIOTENSIN-CONVERTING ENZYME (ACE) INHIBITORS

↘ Mortality; ↘ Hospitalization; Stabilizes remodeling; ↘ Symptoms

STUDIES: ★ CONSENSUS - ★ SOLVD; ★ SOLVD-Prevention (asymptomatic ↘ LVEF - NYHA I); ★ SAVE - ★ AIRE - ★ TRACE (myocardial infarction with heart failure and/or ↘ LVEF); ★ ATLAS (low-dose vs high-dose Lisinopril)

ADVERSE EFFECTS: ARF; hyperkalemia; hypotension; cough (secondary to ↗ bradykinins); angioedema

CONTRAINDICATIONS: angioedema; bilateral renal artery stenosis; pregnancy

› **Caution**: creatinine > 221 µmol/L (> 2.5 mg/dL) or GFR < 30 mL/min/1.73m^2; hyperkalemia > 5.5 mmol/L; SBP < 90 mmHg
  • **< 30% rise in creatinine** or elevation of **K+ up to 5.5 mmol/L** is acceptable +
› **Follow-up**: assessment 1 week after titration (creatinine; BUN; electrolytes)

BETA-BLOCKERS (BB)

↘ Mortality; ↘ Hospitalization; ↘ Remodeling; ↘ Symptoms

STUDIES: ★ CIBIS (Bisoprolol) - ★ COPERNICUS (Carvedilol) - ★ MERIT-HF (Metoprolol succinate XL); ★ SENIORS (Nebivolol; > 70 years); ★ COMET (Carvedilol vs Metoprolol tartrate); ★ B-CONVINCED (BB continued in the presence of decompensation); ★ CAPRICORN - ★ BEAT (post-myocardial infarction)

ADVERSE EFFECTS: decompensated heart failure; bronchospasm; bradycardia / block; hypotension; tiredness; depression; nightmares; erectile dysfunction; glucose intolerance

CONTRAINDICATIONS: **active decompensated heart failure** (continue BB if already used predecompensation); shock - hypoperfusion; asthma; 2nd or 3rd degree AV block; severe PAD (ischemia at rest) +

› **Treat congestion before initiating a BB; target euvolemia** +
› **Titrate the dose every 2 weeks**
› **Caution**: HR < 60 bpm; recent decompensation; NYHA IV; SBP < 90 mmHg
› **COPD**: favor beta-1 selective BB (Bisoprolol; Metoprolol)

MINERALOCORTICOID RECEPTOR ANTAGONISTS (MRA)

↘ Mortality; ↘ Hospitalization; ↘ Symptoms

STUDIES: ★ RALES (NYHA III-IV; LVEF < 35 %); ★ EMPHASIS-HF (NYHA II; LVEF < 30 % or < 35 % with QRS > 130 ms; Recent hospitalization or ↗ BNP); ★ EPHESUS (myocardial infarction; LVEF < 40%; heart failure or DM)

ADVERSE EFFECTS: hyperkalemia; ARF; gynecomastia - impotence - ↘ libido - menstrual irregularities (Spironolactone)

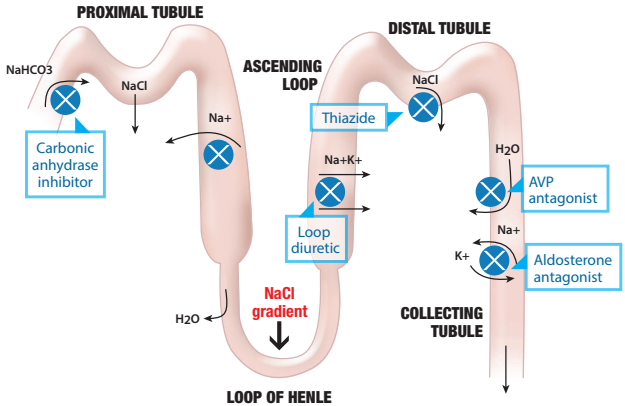
CONTRAINDICATIONS: CRF **(creatinine > 221 µmol/L in males or > 177 µmol/L in females or GFR < 30 mL/min); hyperkalemia > 5 mmol/L** +

› Titration every 4-8 weeks
› **Follow-up**: assessment 1 week and 4 weeks after titration; at 8 weeks - 12 weeks; at 6 - 9 - 12 months; then every 4 months

DIURETICS

↘ Symptoms

Target dry weight; target lowest possible dose



ADVERSE EFFECTS: ARF; hypovolemia; hypokalemia; hyponatremia (thiazides); hypomagnesemia; metabolic alkalosis; hyperuricemia; ototoxicity

CAUTION: CRF; hypokalemia; hypotension

› **Follow-up:** assessment 1 week after titration (creatinine; BUN; electrolytes; Mg^{2+})

› **Target K+ 4-5 mmol/L**

	SODIUM EXCRETION	DURATION OF ACTION	COMMENTS
Loop diuretics	25 %	4-8 h (furosemide)	• Inhibition of the ascending loop Na-K-2Cl pump • **Secreted into the proximal tubule** (this secretion depends on renal perfusion and the bioavailability of the drug) • **Dose–effect response** (a tubular concentration threshold must be reached to obtain an effect) • Venodilator effect
Thiazides	5-10 %	6-12 h (HCTZ) 12-24 h (Metolazone)	• Inhibition of the distal tubule Na-Cl pump • Less effective when GFR < 30 mL/min • ↘ **clearance of free water** (risk of hyponatremia); ↗ Ca^{2+} reabsorption
Mineralo–corticoid receptor antagonists	1-2 %	2-3 h	• Inhibition of the collecting tubule Na-K pump at the site of action of aldosterone • **Antagonism of the harmful effects of aldosterone on the heart**
Vasopressin antagonist	0 %	24 h	• Free water diuresis (aquaretic) • Action on collecting tubule (V2 receptors) • Useful in the presence of hyponatremia; no benefit in ★EVEREST

DIURETIC RESISTANCE

- **Mechanisms**: **A)** Post-sodium excretion stimulation of RAA / sympathetic systems (rebound sodium absorption); **B)** ↘ Drug absorption (edema of intestinal wall); **C)** ↘ Cardiac output (↘ renal perfusion therefore ↘ tubular secretion of the diuretic); **D)** Hypertrophy of distal tubule; **E)** ARF or cardiorenal syndrome
- **Management**
  - **a)** Strict water / NaCl restriction
  - **b)** Increase the dose of the loop diuretic or increase the frequency of administration
  - **c)** Addition of an mineralocorticoid receptor antagonist
  - **d)** Combination of loop diuretic and metolazone (temporary measure; daily assessments)
  - **e)** Continuous Lasix infusion (sustained sodium excretion):
    - 20-40 mg IV bolus then infusion 5-40 mg/h (400 mg/100 mL NS)
  - **f)** Inotropes: Dopamine (renal effect) or Dobutamine or Milrinone
  - **g)** Ultrafiltration: refractory patient (★UNLOAD: ↘ Hospitalization; no benefit in ★CARESS-HF); slow continuous veno-venous method

ANGIOTENSIN RECEPTOR BLOCKERS (ARB)

INDICATIONS: A) Intolerance to ACE inhibitors (cough; angioedema); **B)** In combination with ACE inhibitors if intolerant to mineralocorticoid receptor antagonists and persistent symptoms

STUDIES

- **Intolerance to ACE inhibitors**: ★ CHARM-Alternative (Candesartan); ↘ Cardiovascular mortality; ↘ Hospitalization
- **ARB combined with ACE inhibitors**: ★ Val-HeFT (Valsartan) - ★ CHARM-ADDED (Candesartan); ↘ Cardiovascular mortality (Candesartan); ↘ Hospitalization; ↘ Symptoms
- **Post-myocardial infarction** (with heart failure and/or ↘ LVEF): ★ VALIANT (Valsartan vs Captopril vs Combinaison) → Valsartan non-inferior to Captopril

NEPRILYSIN INHIBITOR

↗ Active natriuretic peptides

★ **PARADIGM-HF**: LVEF ≤ 35-40 %; NYHA II-IV; NTproBNP ≥ 600 pg/ml (or ≥ 400 pg/ml if hospitalized < 12 months); Sacubitril + Valsartan vs Enalapril → ↘ Mortality; ↘ Hospitalization; ↘ Symptoms; ↗ Hypotension; ↗ Angioedema

DOSING (SACUBITRIL/VALSARTAN): stop ACEi 36 h before; start with 50 (24/26) or 100 (49/51) mg bid; double the dose after 2-4 weeks; target dose of 200 (97/103) mg bid if tolerated

IVABRADINE

Inhibits the sinoatrial node I_f current channel

STUDIES: ★ SHIFT (LVEF ≤ 35 %; NYHA II-IV; HR ≥ 70 bpm; recent hospitalization); ↘ Hospitalization; ↘ Symptoms; ↘ Remodeling

ADVERSE EFFECTS: bradycardia; phosphenes

DIGOXIN

Inhibits the Na-K-ATPase pump: ↗ intramyocyte Ca^{2+} (positive inotropic agent); ↗ vagal tone

INDICATIONS: **A)** Persistent symptoms despite standard treatment; **B)** AF (rate control)

STUDIES: ★ DIG (NYHA II-IV; LVEF < 45 %) → ↘ Hospitalization; ↘ Symptoms

Adjustment according to renal function and serum digoxin levels

› **Target serum Digoxin level 0.5 to 0.9 ng/mL** +

ADVERSE EFFECTS: atrial / junctional / ventricular arrhythmias (especially in the presence of hypokalemia) combined with blocks; visual disorders; confusion; GI symptoms

CONTRAINDICATIONS: CRF; bradycardia - blocks

MULTIPLE DRUG INTERACTIONS

› ↗ **Serum Digoxin levels**: Amiodarone; Verapamil; Nifedipine; Diltiazem; Quinidine; Propafenone; Captopril; Carvedilol; Spironolactone; Cyclosporine; Macrolides

HYDRALAZINE - ISOSORBIDE DINITRATE

↘ **Mortality in Afro-Americans;** ↘ Hospitalization; ↘ Symptoms

INDICATIONS: A) Intolerance to ACE inhibitors and ARB; **B)** Persistent symptoms despite BB - ACE inhibitors - MRA **(particularly in Afro-Americans)**

STUDIES: ★ V-HeFT-1 and 2; ★ A-HeFT (Afro-Americans)

ADVERSE EFFECTS: headache; hypotension; nausea; arthralgia; asymptomatic ↗ ANA; drug-induced lupus

NON-PHARMACOLOGICAL TREATMENT

SELF-SURVEILLANCE OF WEIGHT

› Daily weight; on waking; before getting dressed; post-voiding → increase the dose of diuretics or notify if weight ↗ > 1.5-2 kg or 3-4 lbs (x 2-3 days)

SODIUM: < 2-3 g per day

FLUIDS: < 2 liters per day (especially if hyponatremia or refractory congestion)

VACCINATION: influenza (annually); pneumococcus (every 5 years)

TREATMENTS TO BE AVOIDED: **A)** Thiazolidinediones; **B)** Non-dihydropyridine CCBs; **C)** NSAIDs; **D)** Certain AAD: Dronedarone (★ ANDROMEDA); Class I AAD (★ CAST); **E)** Alpha-blockers

EXERCISE

★ **HF-ACTION** → improves symptoms and functional capacity

Regular isotonic exercise (walking; stationary bike) after stress test (rule out ischemia - arrhythmia)

› **Prescription**: 3-5 times a week; 30-45 min; **60-70% of peak heart rate** (or peak VO_2) **or 4-5-6/10 on Borg's scale** (▶▶| Chapter 9)

IMPLANTABLE CARDIAC DEFIBRILLATOR (ICD)

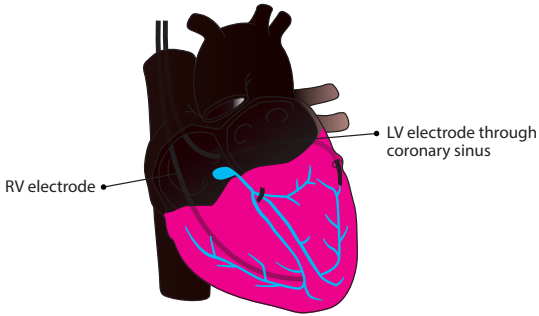
SECONDARY PREVENTION: defibrillator indicated

PRIMARY PREVENTION

› **Studies**: ★ SCD-HeFT (nonischemic cardiomyopathy or ischemic heart disease; NYHA II-III; LVEF ≤ 35% [mean = 25%]) and ★ MADIT-II (ischemic heart disease; LVEF ≤ 30%; NYHA I-III) → ↘ mortality

› **Avoid in NYHA IV (except when the patient is a candidate for transplant or mechanical support) due to poor prognosis and death predominantly secondary to progressive heart failure** +

CARDIAC RESYNCHRONIZATION THERAPY (CRT)



INDICATIONS

✓ **AMBULANT, NYHA III OR IV** ✓ **LVEF ≤ 35 %** ✓ **LBBB – QRS ≥ 120 MS** ✓ **SINUS RHYTHM** ✓ **LIFE EXPECTANCY > 1 YEAR**	✓ **NYHA II** ✓ **LVEF ≤ 30 %** ✓ **LBBB – QRS ≥ 120–130 MS** ✓ **SINUS RHYTHM** ✓ **LIFE EXPECTANCY > 1 YEAR**
STUDIES: ★ CARE-HF - COMPANION ↘ Mortality; ↘ Hospitalization; ↘ Symptoms; Reverse remodeling	**STUDIES: ★ RAFT - MADIT-CRT** ↘ Mortality (★ RAFT); ↘ Hospitalization; ↘ Symptoms; Reverse remodeling

UNCERTAIN BENEFICIAL EFFECTS OF RESYNCHRONIZATION

a) **Permanent AF with above indications** (consider AV node blocking agents or AV node ablation to force resynchronization)
b) **Patient with systolic dysfunction and frequent RV pacing** (consider resynchronization **if significant RV pacing > 40%)** +

PROCEDURAL SUCCESS: 90 %

› Minithoracotomy approach with epicardial lead PRN
› **Complications (14% in ★ RAFT)**: pneumothorax; pocket hematoma; pocket infection; lead migration; coronary sinus perforation / dissection (1%)

PARAMETERS INFLUENCING THE RESPONSE TO RESYNCHRONIZATION: % biventricular pacing; baseline degree of asynchrony (QRS ≥ 150 ms); lead position (target = basal lateral branch of CS); lead pacing scar tissue; ischemic heart disease << nonischemic cardiomyopathy; CRT programming (AV delay; VV delay)

› **Non-responders**: 30 %

ATRIAL FIBRILLATION

RATE CONTROL: **non-inferior to rhythm control (★ AF-CHF)** +

› **A)** BB; **B)** Digoxin; **C)** Amiodarone to control HR as necessary (patient should be anticoagulated for 1 month because of the risk of CCV); **D)** AV node ablation + PPM; consider resynchronization

RHYTHM CONTROL: patients with severe symptoms or reversible cause / precipitating factor

› **A)** ECV; **B)** Amiodarone or Dofetilide; **C)** ± PV isolation (benefit in ★ PABA-CHF and ★ AATAC-AF)

WARFARIN - ANTICOAGULATION

INDICATIONS: **A)** AF; **B)** Thrombus; **C)** History of thromboembolic disease

No benefit in ★ WARCEF study (LVEF < 35% in SR; for thromboembolic primary prevention)

SLEEP-DISORDERED BREATHING

CENTRAL SLEEP APNEA - CHEYNE-STOKES (40%): hyperventilation followed by apnea (≥ 10 s with no ventilatory effort); **associated with pulmonary congestion**; independent risk factor of mortality

- **Diagnosis**: Polysomnography
- **Treatment**: Optimize management of heart failure; CPAP (no benefit in ★ CANPAP study); Adaptive servo-ventilation associated with ↗ mortality in ★ SERVE-HF

OBSTRUCTIVE SLEEP APNEA (10%): Leads to hypoxemia / hypercapnia / intermittent sympathetic stimulation

- Look for obesity / ↗ neck circumference; snoring; daytime sleepiness; apneas
- **Complications**: refractory HTN; nocturnal HTN; PHT; arrhythmias
- **Diagnosis**: Polysomnography (screening with nocturnal saturometry)
- **Treatment**: Weight loss; CPAP

ANEMIA

Multifactorial

TREATMENT: Transfusions; IV iron (★ FAIR-HF; ★ CONFIRM HF); no benefit for EPO (★ RED-HF)

ISCHEMIC LEFT VENTRICULAR SYSTOLIC DYSFUNCTION

REVASCULARIZATION: possible benefit in the presence of significant viability; highly controversial topic (mixed results of ★ STICH study; ★ ISCHEMIA study ongoing)

FUNCTIONAL MITRAL REGURGITATION

Carpentier I and IIIb mechanisms; maintains systolic dysfunction (which maintains MR)

MVR OR MITRAL ANNULOPLASTY: possible improvement in functional class; associated with reverse remodeling; no convincing data on survival; MVR possibly superior (★ CTSN)

- Consider in severe secondary MR with: CABG or concomitant AVR (class IIa recommendation) or refractory NYHA III - IV (class IIb recommendation)

MITRACLIP: consider in the presence of significant MR with refractory symptoms in a patient who is not a candidate for surgery

3.3/ DIASTOLIC HEART FAILURE (preserved LVEF)

Secondary to abnormal active relaxation and/or ↗ passive rigidity

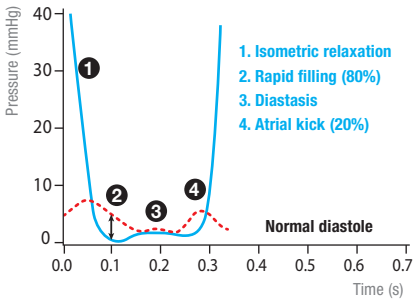
50% of patients with heart failure

ALL-CAUSE MORTALITY similar to that of heart failure with ↘ LVEF

- Mortality is mostly due to non-cardiovascular causes

RISK FACTORS: Age; Female; HTN; LVH; Ischemia; DM; Obesity; RCM; HCM

FACTORS ASSOCIATED WITH DECOMPENSATION: uncontrolled / labile HTN; AF; Ischemia; Volume overload; Extracardiac cause



DIASTOLIC DYSFUNCTION
Abnormal relaxation
and/or ↑ passive rigidity
↓
↑ Filling pressures
↓
↑ LA pressure

ETIOLOGIES OF ↓ RELAXATION VELOCITY
- ↑ LV afterload
- Ischemia
- Age
- Systolic dysfunction (↓ recoil)
- LVH

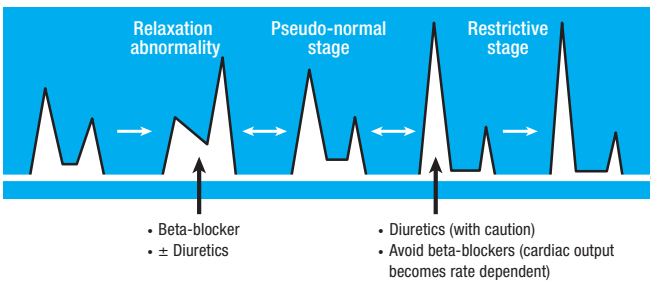
TTE: LVH - concentric remodeling; diastolic pattern; filling pressures; LA dilatation; PAP; RV function; Rule out pericardial disease

› ↗ **Filling pressures**: E/e' > 15; E/A inversion with Valsalva; diastolic dominance (PV outflow); prolonged reversal of flow in PV during atrial kick; LA dilatation; PHT

STRESS TEST: Rule out exaggerated hypertensive response (which exacerbates diastolic dysfunction); Rule out chronotropic incompetence

BNP: less sensitive than in systolic heart failure

MANAGEMENT



No treatment proven to decrease morbidity or mortality

› **No benefit in**: ★ CHARM-Preserved - ★ PEP-CHF - ★ I-Preserve - ★ TOPCAT - ★ NEAT-HFpEF

DIURETICS: symptoms / congestion control

RISK FACTOR REDUCTION: CAD; HTN (rule out renovascular syndrome in the presence of refractory HTN)

REVASCULARIZATION: if significant ischemia / symptoms

RATE CONTROL during AF (± rhythm control)

CONSIDER: ACE inhibitor or ARB; BB; MRA

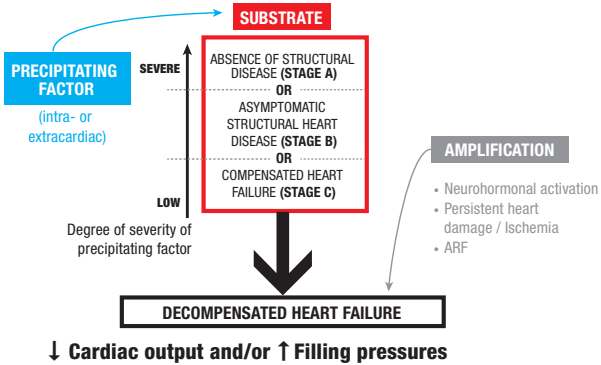
3.4/ DECOMPENSATED HEART FAILURE

Acute or subacute onset or modification of symptoms and signs of heart failure

Decompensated chronic heart failure (80%) vs *de novo* heart failure (20%)

50% of patients have preserved LVEF

PATHOPHYSIOLOGY



↓ Cardiac output and/or ↑ Filling pressures

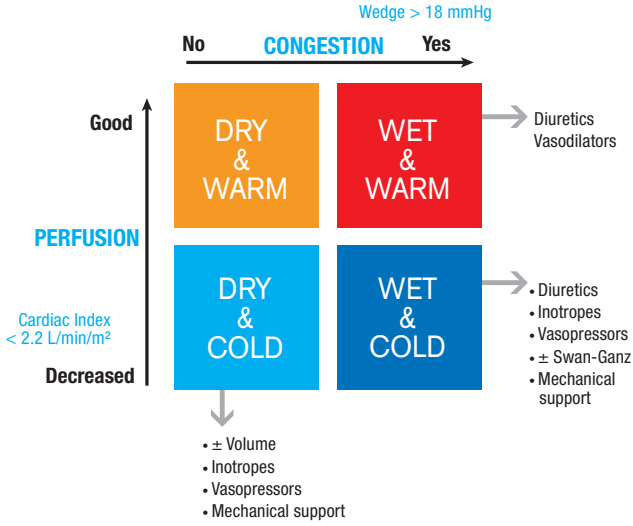
VARIOUS SCENARIOS

TAS > 160; ACUTE PULMONARY EDEMA	NORMAL BP	HYPOTENSION (SBP < 90)
• LVEF often preserved • Acute pulmonary edema • **Treatment**: Vasodilators; Diuretics; BiPAP; Rule out renal artery stenosis	• Systemic congestion • Subacute (often decompensated chronic heart failure) • **Treatment**: Diuretics; ± Vasodilators	• Low output • Renal hypoperfusion • **Treatment**: Positive inotropes (Milrinone; Dobutamine); Vasopressors; Mechanical support
CARDIOGENIC SHOCK	**MYOCARDIAL INFARCTION (KILLIP II OR III)**	**RIGHT HEART FAILURE**
• Acute event (ACS; mechanical complication; fulminant myocarditis) • **Treatment**: Reperfusion; Positive inotropes; Vasopressors; IABP; Mechanical support; Surgery	• Rapid onset • Resolution with treatment of ischemia • **Treatment**: Reperfusion; Nitrates; Ensure good coronary perfusion pressure	• RV infarction; PHT; Pulmonary embolism • Hypotension / systemic congestion • Interventricular dependence: RV dilatation induces ↘ LV filling • **Treatment**: Diuretics; Inotropes; Reperfusion; Pulmonary vasodilators

PRECIPITATING FACTORS

ACUTE DETERIORATION	SUBACUTE DETERIORATION
• Tachyarrhythmia • Bradyarrhythmia - Blocks • Acute coronary syndrome / Ischemia • Mechanical complication of MI • Valvular heart disease (e.g.: ischemic MR) • Pulmonary embolism • Hypertensive crisis • Cardiac tamponade • Aortic dissection • Surgery • Hemorrhage • Endocarditis	• Infection • COPD exacerbation / Asthma • ARF • Nonadherence to treatment • Nonadherence to restrictions • Drugs (NSAID; corticosteroids; Pregabalin) • Arrhythmias - Blocks • Uncontrolled HTN • Hypothyroidism / Hyperthyroidism • Alcohol - Illicit drugs • Anemia • LBBB • Progression of heart disease

MANAGEMENT



- Monitor
- Vital signs - SaO_2
- Urine output
- SVO_2

ACUTE HEART FAILURE

↗ FILLING PRESSURES / CONGESTION
(Wedge > 18 mmHg and/or CVP > 8 mmHg)

and/or

↘ CARDIAC OUTPUT
(< 2.2 L/min/m²)

- Diuretics (Lasix)
- Vasodilators (Nitrates)
- Morphine
- O_2 (target SaO_2 > 92 %)
- BiPAP or Mechanical ventilation if respiratory failure

TARGET ORGAN HYPOPERFUSION

- Cold skin
- Urine output < 20 mL/h
- SVO_2 < 70 %
- Confusion
- Ischemia

Rule out reversible cause

Hemodynamic instability and/or ↘ systemic vascular resistance

Maintain perfusion of vital organs (heart; CNS)
- Vasopressors (Norepinephrine; Dopamine)
- Non-vasodilator inotropes

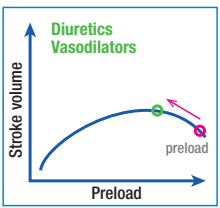
Normal systemic vascular resistance (1000 - 1200 dynes x s/cm⁵)

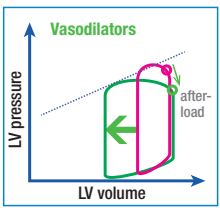
- Inotropes
- Vasodilators

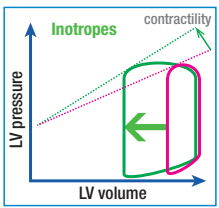
↗↗ systemic vascular resistance

- Vasodilators
- Inotropes

- Intra-aortic balloon pump
- Short-term percutaneous ventricular support (ECMO; Impella; TandemHeart) as "bridge to decision"







VASODILATORS		
Nitroglycerin	Dose: 10-20 µg/min up to 200 µg/min Standard dilution: 50 mg/250 mL D5% = 200 µg/mL	• ↗ cGMP in smooth muscle cells (= vasodilatation) • Venous vasodilator (↘ filling pressures) then arterial (↘ afterload; coronary vasodilatation) • Adverse effects: Tolerance during prolonged use; Hypotension; Headache
Nitroprusside	Dose: 0.3 µg/kg/min up to 5 µg/kg/min Standard dilution: 50 mg/250 mL NS = 200 µg/mL	• Balanced vasodilator • Short half-life • Used for hypertensive emergency or acute MR • Adverse effects: Risk of cyanide toxicity; Hypotension
Nesiritide	• Bolus: 2 µg/kg • Perfusion: 0.01-0.03 µg/kg/min	• Recombinant BNP • Balanced vasodilator • No benefit in ★ ROSE-AHF and ★ ASCEND-HF
INOTROPES		
Dobutamine	Dose: 2-20 µg/kg/min Standard dilution: 250 mg/ 100 mL D5% = 2500 µg/mL	• Beta-1 and beta-2 agonist • Supplementary alpha-1 effect at higher doses (neutralizing the beta-2 vasodilator effect) • **Favor to Milrinone in the presence of significant hypotension** • Arrhythmogenic
Dopamine	• Renal effect (Dopamine) < 3 µg/kg/min • Beta-1: 3-5 µg/kg/min • Alpha-1 (and Beta-1): > 5 µg/kg/min (up to 20 µg/kg/min) Standard dilution: 400 mg / 250 mL D5% = 1600 µg/mL	• Dose-dependent effect • Positive inotrope and vasopressor (vasodilator at low doses) • Norepinephrine precursor • Arrhythmogenic • ↗ Mortality in cardiogenic shock (★ SOAP II)
Milrinone	• Bolus: 25-75 µg/kg x 10-20 min (optional; avoid if hypotension) • Infusion: 0.375 - 0.75 µg/kg/min • Adjustment to GFR Standard dilution: 10 mg/100 mL D5% = 90 µg/mL	• Phosphodiesterase inhibitor (↗ intramyocyte cAMP = ↗ intracellular Ca^{2+}) • Risk of hypotension (vasodilator) • Caution in patients with CAD (hypotension can accentuate ischemia) • Effective despite BB • Favor if BP preserved • Less arrhythmogenic than dobutamine • No benefit in ★ OPTIME-HF study
Levosimendan	• Bolus: 12 µg/kg x 10 min (optional; risk of hypotension) • Infusion 0.05 - 0.2 µg/kg/min	• Calcium sensitizer • Positive inotrope and vasodilator • Equivalent to Dobutamine in ★ SURVIVE

Isuprel	Dose: 0.5 to 10 µg/min Standard dilution: 1 mg / 250 mL D5% = 4 µg/mL	• Beta-1 and beta-2 agonist • Prominent positive chronotropic effect • Risk of hypotension (beta-2 effect)
VASOPRESSORS		
Norepine-phrine	Dose: 0.2 -1 µg/kg/min Standard dilution: 4 mg / 250 mL D5% = 16 µg/mL	• Alpha-1 agonist • Beta-1 effect (but reflex bradycardia secondary to ↗ MAP)
Epinephrine	• Bolus: 1 mg IV every 3-5 min (during resuscitation) • Infusion: 0.05 - 0.5 µg/kg/min Standard dilution: 5 mg / 250 mL D5% = 20 µg/mL	• Alpha-1, beta-1 and beta-2 agonist • Arrhythmogenic
Phenylephrine	Dose: 40 - 60 µg/min Standard dilution: 10 mg / 250 mL NS = 40 µg/mL	• Pure alpha-1 agonist

MONITORING: Cardiac monitoring - Regular vital signs - SaO_2 - urine output; daily weight

LMNOP: IV Lasix; Morphine if anxiety / distress (2.5-5 mg IV); Nitrates (avoid if hypotension); O_2; Position - PEEP

› **Diuretic**: ★ DOSE study → bolus bid equivalent to IV infusion; low-dose IV (equal to usual oral doses) equivalent to high-dose IV (2.5 x usual oral doses)
› **BiPAP**: contraindicated in the presence of hypotension; Vomiting; Impaired level of consciousness; Uncooperative patient

INOTROPES (Dobutamine; Milrinone): **indicated in the presence of peripheral hypoperfusion**

› **Adverse effects**: Hypotension (vasodilator effect); Arrhythmogenic; ↗ O_2 demand; ↗ Long-term mortality

VASOPRESSORS (Norepinephrine): indicated in the presence of severe hypotension

› **Objective**: **redirect cardiac output to vital organs**
› **Adverse effects**: ↗ Afterload; ↗ O_2 demand; Arrhythmogenic

SWAN-GANZ: Indications → **A)** Cardiogenic shock despite inotropes / vasopressors; **B)** Patient refractory to treatment; **C)** Uncertain hemodynamic parameters (filling pressures; SVR); **D)** Hemodynamic assessment prior to transplant / mechanical support

› **Hemodynamic targets**

WEDGE	CVP	BP	SVO_2	SVR	CARDIAC INDEX
< 18 mmHg	< 8 mmHg	MAP > 60 mmHg SBP > 80 mmHg	> 70 %	1000 to 1200 dynes x s/cm^5	> 2.2 L/min/m^2

MONITORING OF TREATMENT: improvement in symptoms / signs of congestion / peripheral perfusion; SVO_2; BP; weakness - OH; urine output; daily weight; CVP; BUN - creatinine - electrolytes

IDENTIFICATION AND TREATMENT OF REVERSIBLE CAUSES: Ischemia; Arrhythmia; Valvular heart disease; Other precipitating factors

DISCHARGE FROM HOSPITAL: congestion resolved; **dry weight achieved**; ACE inhibitors - BB - mineralocorticoid receptor antagonist initiated; stable dose of diuretics and stable labs for > 48 h; restrictions explained; registration in specialized clinic; follow-up < 1 month (vulnerable phase)

SHORT-TERM AND MEDIUM-TERM MECHANICAL SUPPORT

OBJECTIVE: **Maintain adequate target organ perfusion** during acute treatment and/or while waiting for recovery and/or while waiting for heart transplant or long-term ventricular support

SHORT-TERM PERCUTANEOUS MECHANICAL SUPPORT

- **IABP**: increases cardiac output **< 10-15 %**; increases coronary perfusion; contraindicated in the presence of AR or aortic dissection
- **Impella 2.5 and 5.0 L/min**: Femoral artery → Aortic valve
- **TandemHeart**: **A)** Filling cannula: femoral vein → transseptal → LA; **B)** Ejection cannula: femoral artery
  - **Disadvantages** (Impella and TandemHeart): lower limb ischemia; cannula displacement; difficult transport
- **ECMO**: complete cardiopulmonary support
  - **Disadvantages**: anticoagulation; lower limb ischemia; incomplete LV decompression; requires qualified personnel; activation of an inflammatory cascade

MEDIUM-TERM MECHANICAL SUPPORT (LVAD OR RVAD OR PARACORPOREAL BIVAD)

Thoratec VAD; CentriMag; Abiomed BVS5000

CARDIORENAL SYNDROME

Impaired renal function associated with heart failure

MECHANISMS: **A)** Low output; **B)** Venous congestion; **C)** Medications (ACE inhibitors; ARB; contrast agents); **D)** Intravascular hypovolemia (diuretics) = activation of RAA / sympathetic systems; **E)** Underlying renal disease (HTN; DM; PAD); **F)** ↗ Intra-abdominal pressure (ascites)

RENAL PERFUSION PRESSURE = MAP - CVP

NORMAL RENAL FUNCTION	**GFR > 90 mL/min/1.73 m²**
STAGE II CRF	**GFR 60 - 89 mL/min/1.73 m²**
STAGE III CRF	**GFR 30 - 59 mL/min/1.73 m²**
STAGE IV CRF	**GFR 15 - 29 mL/min/1.73 m²**
STAGE V CRF	**GFR < 15 mL/min/1.73 m²**

3.5/ HEART TRANSPLANTATION

INDICATION

Late-stage heart disease after optimal medical / surgical therapy, in presence of an unacceptable quality of life and a poor anticipated survival

Late-stage heart failure; Severe refractory ischemic symptoms; Refractory life-threatening arrhythmias; Complex congenital heart disease...

- **Cardiopulmonary stress testing** to guide transplant listing (reach anaerobic threshold)
  - Peak VO_2 **≤ 12 mL/kg/min** (in the presence of a beta-blocker)
  - Peak VO_2 **≤ 14 mL/kg/min** (patients intolerant to beta-blockers)
  - Percent of predicted peak VO_2 ≤ 50% (in young patients)
- **Heart failure prognosis score** to guide transplant listing
  - Seattle Heart Failure Model: 1-year survival < 80%
  - Heart Failure Survival Score: High / Medium risk

ASSESSMENT

POTENTIAL DONOR: cold ischemia time < 4 h; TTE; coronary angiography (depending on risk factors / age); donor size

IMMUNOLOGICAL WORK-UP: blood group; antibody screening; Panel reactive antibody (PRA); specific HLA antibodies (directed against human leukocyte antigens)

- **PRA > 10 %**: recipient patient sensitized; ↗ risk of humoral rejection
  - **Management**: IV Ig; Rituximab; plasmapheresis

CONTRAINDICATIONS

- **Fixed high pulmonary vascular resistances**
  - **Pulmonary vascular resistances > 5 WU**
  - **Transpulmonary gradient (mPAP – Wedge) > 16-20 mmHg**
  - **Pulmonary vascular resistance index (TPG / CI) > 6**
  - **Pulmonary vascular resistances > 2.5 WU in response to pharmacological challenge while maintaining SBP > 85 mmHg (NO; Nitroprusside; Prostanoids; Inotropes)**
    - High risk of RV failure and mortality after cardiac transplantation
    - Consider aggressive medical therapy (diuretics; inotropes; IV vasodilators; NO) and temporary mechanical support (IABP; LVAD) to improve these parameters
- **Others**: **A)** Irreversible renal dysfunction (GFR < 30 mL/min); **B)** Irreversible significant liver disease (biopsy PRN); **C)** Pre-existing cancer when the risk of tumor recurrence is significant; **D)** Active infection; **E)** Clinically severe symptomatic cerebrovascular disease; **F)** Peripheral arterial disease when it limits rehabilitation; **G)** DM with target organ damage or persistent poor glycemic control (HbA1c > 7.5%); **H)** Active mental illness / Nonadherence; **I)** Active smoking (previous 6 months) or active substance abusers (including alcohol); **J)** Obesity (BMI > 35 kg/m²); **K)** Age > 70 years old (consider selected patients); **L)** Frailty

PRIORITY ALLOCATION SYSTEM

STATUS 4	• Dependent on mechanical support (or mechanical ventilation) and in the intensive care unit
STATUS 3.5	• In-hospital inotrope-dependent (high doses or multiple agents) • Highly sensitized patient • Refractory life-threatening arrhythmia
STATUS 3	• Uncomplicated LVAD / without intensive care • In-hospital on inotropes (low dose / only one agent) • Congenital heart disease › arterial shunt-dependent › with SaO_2 < 65 % › complex with progressive arrhythmia › complex with systemic ventricle decline • Heart-lung transplantation
STATUS 2	• In-patient • Outpatient on inotropes • Congenital heart disease › with SaO_2 65-75 % › with Fontan and exudative enteropathy • Multiple organ transplantation (other than heart-lung)
STATUS 1	• Other

Canadian Cardiac Transplant Network

IMMUNOSUPPRESSION

INDUCTION
- **Anti-IL2 receptor antibodies** (Basiliximab) or **rATG** (antithymocyte immunoglobulins)
- **Precise indications**: high risk of rejection; risk of renal toxicity with calcineurin inhibitors

CORTICOSTEROIDS
- Decrease lymphocyte activation (T cells and B cells)
- Tapering after 6 months
- **Adverse effects:** Cushing; HTN; dyslipidemia; weight gain; DM; ulcers; cataracts; avascular necrosis of the hip; osteoporosis; shingles

CALCINEURIN INHIBITORS: CYCLOSPORINE OR TACROLIMUS
- Decrease T cell activation
- **Adverse effects:** Nephrotoxicity; HTN; DM; Neurotoxicity...

+

PURINE SYNTHESIS INHIBITORS: AZATHIOPRINE OR MMF (MYCOPHENOLATEMOFETIL)
- Inhibit T cell and B cell proliferation
- **Adverse effects:** Bone marrow suppression; Granulocytopenia; Diarrhea; Interaction with Allopurinol (Azathioprine)

M-TOR INHIBITORS: SIROLIMUS (RAPAMYCIN) AND EVEROLIMUS
- **Alternative to calcineurin inhibitors in the presence of renal toxicity**
- Block T cell (and B cell) activation
- Inhibit endothelial cell and fibroblast proliferation
  - › **Decrease the risk of cardiac allograft vasculopathy**
- **Adverse effects:** Altered healing

COMPLICATIONS

TRANSPLANT: bicaval anastomosis

POST-TRANSPLANT HEART FAILURE: optimize coronary perfusion; optimize RV preload (diuretics; UF; minimize transfusions); atrial pacing (junctional rhythm is common post-transplant); avoid hypercapnia - acidosis; inotropes (Milrinone; Dobutamine); pulmonary vasodilators (NO; Prostacyclins; Sildenafil); IABP - ECMO - RVAD - Impella

CELLULAR REJECTION: **Lymphocyte infiltrates (T cells)**; several weeks to several years post-transplant; 40% in the first year
- › **Presentation**: **ranges from asymptomatic to cardiogenic shock**
- › **Diagnosis**: weekly biopsy for 6 weeks - monthly for 6 months - every 3 months for 2 years - every 4 to 6 months
- › **Risk factors**: Young age; female; CMV+; HLA incompatibility
- › **Treatment:** corticosteroids; intensification of immunosuppression

GRADE 0 R	Absence of rejection
GRADE 1 R (MILD)	Interstitial / Perivascular lymphocyte infiltration (≤ 1 zone of myocyte injury)
GRADE 2 R (MODERATE)	≥ 2 zones of infiltration with myocyte injury
GRADE 3 R (SEVERE)	Diffuse infiltration; multiple zones of myocyte injury (± edema; ± bleeding; ± vasculitis)

HUMORAL REJECTION (ANTIBODIES): **anti-donor HLA antibody or anti-endothelial antigen antibody**; absence of lymphocyte infiltrate; acute graft dysfunction (↘ LVEF)

› **Treatment**: Plasmapheresis; Corticosteroids; Rituximab

CLINICAL	• Graft dysfunction; ↘ LVEF; Wall thickening (edema)
HISTOLOGICAL (BIOPSY)	• Capillary endothelial congestion (± interstitial edema) • Macrophages in capillaries (± neutrophils)
IMMUNO-PATHOLOGICAL	• Immunofluorescence: Immunoglobulins + complement (C3d / C4d / C1q) in capillaries • Immunohistochemistry: CD68+ macrophages in capillaries or C4d in capillaries
SEROLOGICAL	• Anti-HLA class I or II antibodies or other anti-donor antibodies

CHRONIC REJECTION: chronic humoral rejection ± cardiac allograft vasculopathy

CARDIAC ALLOGRAFT VASCULOPATHY: 50% at 10 years; **diffuse concentric neointimal proliferation; no angina (denervation)**

› **Complications**: MI; allograft heart failure; arrhythmia; sudden death
› **Risk factors:** number of episodes of rejection; HLA incompatibility; conventional risk factors for CAD; graft ischemia time; donor age; CMV+...
› **Screening**: Dobutamine echocardiography; MIBI-P; Coronary angiography / IVUS
› **Treatment**: Statins; Control of conventional risk factors; Intensification of immunosuppression; m-TOR inhibitors; PCI; re-transplantation

INFECTION: nosocomial (early); fungal (Aspergillosis; Candidiasis); CMV (fever; leukopenia; transaminase elevation); HSV; VZV; PCP; Toxoplasmosis; TB; Nocardiosis; Cryptococcosis; *L. monocytogenes*

› **Prophylaxis (6-12 months post-transplant)**: CMV (Acyclovir / Valganciclovir); *Pneumocystis carinii* and Toxoplasmosis (TMP/SMX); Antifungal agents (Voriconazole / Itraconazole)

NEOPLASIA: 30% at 10 years (lymphoma; cutaneous; solid organs)

OTHER COMPLICATIONS: HTN; Dyslipidemia; DM; CRF (calcineurin inhibitors); sinus tachycardia at rest (parasympathetic denervation); gout

› **Mean survival**: 10 years

3.6/ LONG-TERM VENTRICULAR ASSIST DEVICE

INDICATIONS

ADVANCED HEART FAILURE* • **NYHA IIIb – IV** and • **≥ 2 of these elements:**	• LVEF < 25% and/or VO_2 max < 14 mL/kg/min (or < 50% predicted for age / gender / BSA) • Inotrope dependence • Progressive target organ dysfunction due to hypoperfusion • Repeated hospitalizations (≥ 3 per year) • Progressive discontinuation of beneficial medication (ACE inhibitors; BB) due to hypotension or ARF

***Estimated one-year mortality > 50% on medical therapy** (Seattle Heart Failure Model; Heart Failure Survival Score)

SCENARIOS

BRIDGE TO DECISION	Acute hemodynamic collapse; maintain the patient alive in order to evaluate other therapeutic options; **short-term / medium-term mechanical support** (percutaneous or paracorporeal)
BRIDGE TO RECOVERY	Maintain the patient alive until recovery of sufficient cardiac function to wean mechanical support (by reverse remodeling); acute fulminant myocarditis or sometimes DCM or peripartum cardiomyopathy or following cardiac surgery or myocardial stunning
BRIDGE TO TRANSPLANTATION	Maintain the patient alive while waiting for transplantation
BRIDGE TO CANDIDACY	Improve target organ function to potentially make the patient eligible for transplantation
DESTINATION THERAPY	Use of long-term mechanical support (patient not a candidate for transplantation, but satisfactory life expectancy)

INTERMACS CLASSIFICATION

	INTERMACS PROFILE	TIME TO MECHANICAL SUPPORT
1	CRASHING AND BURNING - Critical cardiogenic shock	Hours
2	PROGRESSIVE DECLINE - Positive inotrope-dependent; continuous deterioration	Days
3	STABLE BUT INOTROPE-DEPENDENT - Stable	Weeks
4	RECURRENT HEART FAILURE - Recurrent decompensation	Weeks - Months
5	EXERTION INTOLERANT - Comfortable at rest	Variable
6	EXERTION LIMITED - Fatigue with the slightest exertion	Variable
7	ADVANCED NYHA III - Comfortable at an acceptable level of exertion	Not a candidate

ASSESSMENT

Refer the patient for assessment before significant irreversible target organ damage (RV dysfunction; Irreversible PHT; irreversible congestive liver disease; irreversible renal failure; coagulopathy; malnutrition) +

- **Target CVP < 15 mmHg** (decreases hepatic congestion; decreases the risk of post-LVAD right heart failure)
- **Right ventricular stroke work index (RVSWI)** = [(mPAP - CVP) x stroke volume] / BSA
  - **Target RVSWI > 300 mmHg x mL/m²**
  - **Mean PAP < 25 mmHg associated with low right ventricular reserve** +
- **Liver disease**: risk of bleeding and post-op transfusion (with deterioration of RV function due to secondary volume overload)

› **Assessments**: Target → BUN < 40 U/dL; creatinine < 221 µmol/L; GFR > 50 mL/kg/min; INR < 1.2; Hb > 100 g/L; Platelets > 150,000/mm³; Albumin > 30 g/L; Prealbumin > 15 g/L; ALT - AST < 2 ULN

› **Valvular heart disease**: correct AR ≥ 3/4 or moderate MS or TR ≥ 3/4 or mechanical AVR

RISK OF POST-LVAD IN-HOSPITAL MORTALITY

PARAMETERS	POINTS	
Platelets < 148 000 / mm³	7	**POST-LVAD IN-HOSPITAL SURVIVAL** • 0-8 points: 87.5 % • 9-16 points: 70.5 % • 17-19 points: 26 % • > 19 point: 13.7 % **If ≥ 17 points: patient optimization prior to LVAD**
Albumin < 33 g/L	5	
INR > 1.1	4	
Ongoing vasodilator therapy	4	
Mean PAP < 25 mmHg	3	
AST > 45 IU/mL	2	
Hematocrit < 34 %	2	
BUN > 51 U/dL	2	
Absence of IV inotrope	2	

Lietz K, Long JW, Kfoury AG, et al. Circulation. 2007;116:497-505

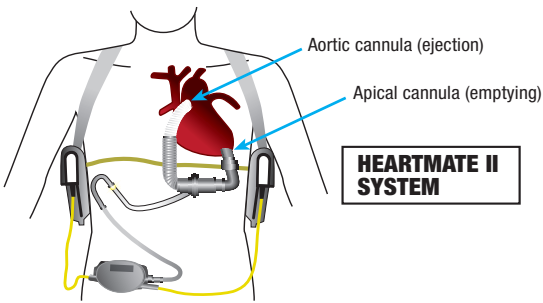
LEFT VENTRICULAR ASSIST DEVICE (LVAD)

"DESTINATION THERAPY" STUDIES: ★ REMATCH (HEARTMATE XVE) and ★ HEARTMATE II → ↘ Mortality compared to conventional medical therapy; Improvement in NYHA class and quality of life; Reverse remodeling

› **2-year survival (registries)**: 65 %

SECOND-GENERATION LVAD PUMPS: **non-pulsatile flow (continuous)**; HeartMate II; Jarvik 2000

› **Flow rate**: up to 10 L/min
› **Pump speed**: adjusted by TTE (LV and RV chambers; position of IV septum; Ao valve opening every 3 beats)
› **Anticoagulation**: Target INR 2 to 3 ± ASA 80 qd
› **BP monitoring (continuous flow pump)**: use sphygmomanometer and Doppler (target mean BP < 80 mmHg)



COMPLICATIONS: bleeding (acquired vWF deficiency; AV malformation); HIT; right heart failure; thromboembolism; stroke; infection; mechanical breakdown; fused aortic valve leaflets (leads to AR or AS); allosensitization; hemolysis; device thrombosis

THIRD-GENERATION PUMPS: HeartWare HVAD (intrapericardial)

MICROPUMPS: CircuLite Synergy (partial support up to 3 L/min; subclavian approach)

3.7/ RIGHT HEART FAILURE

ETIOLOGIES

- Right heart failure secondary to left heart failure (most frequent)
- Precapillary PHT (including pulmonary embolism)
- Cardiomyopathy with RV involvement (including ARVD) (▶▶| Chapter 5 - Cardiomyopathies)
- RV infarction
- Right valvular heart disease
- Congenital heart disease (including ASD and intracardiac shunt)
- Right heart failure post-cardiac surgery
- Constrictive pericarditis (mimics right heart failure)

SYMPTOMS AND SIGNS

- Fatigue; anasarca - edema; anorexia; nausea; RUQ pain
- Hypotension; JVD ± Kussmaul; left parasternal heave ; Harzer's sign; ± signs of PHT; right S3 (↗ inspiration); tricuspid regurgitation; hepatomegaly - pulsatile liver; systemic congestion (ascites; edema)

ASSESSMENT

TTE; radionuclide ventriculography; cardiac MRI; V/Q scintigraphy; Right-Left catheterization

MANAGEMENT

Diuretics (caution in the presence of normal Wedge pressure due to the risk of decreased LV preload); ± mineralocorticoid receptor antagonists

Specific treatment of PHT; Specific treatment of LV HF

Surgical or percutaneous correction of structural abnormality (valvular or congenital malformation)

3.8/ PALLIATIVE CARE

- Discussing the patient's wishes at the stage of advanced heart failure
- Good communication with the patient and family
- Desactivation of the defibrillator
- Analgesia
- ± IV diuretics; ± palliative IV inotropes

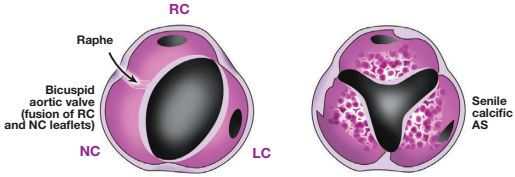
4.1/ AORTIC STENOSIS

ETIOLOGIES

SENILE CALCIFIC AS: Similar risk factors and pathophysiology to CAD and mitral annular calcification (MAC)

BICUSPID AORTIC VALVE

- 1-2% of the population
- **70-80%: fusion of right and left coronary leaflets**
  - 20-30%: fusion of right coronary and non-coronary leaflets
  - Fusion of non-coronary and left coronary leaflets is rare
- **TTE**: Demonstrates valve opening during systole with **only two commissures** (unicuspid valve: only one commissure)
- Screening TTE should be performed in 1st degree relatives
- **Associated aortopathy** (medial degeneration); **aneurysm; dissection**
  - Imaging (TTE; CT angiography; MRI) annually if aorta > 45 mm
  - BB if aorta > 40 mm (in the absence of significant AR)
  - **Ascending aorta replacement if aorta > 55 mm (> 45 mm when AVR is also necessary) or > 50 mm with risk factors for dissection (family history or progression ≥ 5 mm/year)**



RHEUMATIC: fusion of commissures; triangular orifice; concomitant AR and AS; associated mitral valve disease in the majority of cases

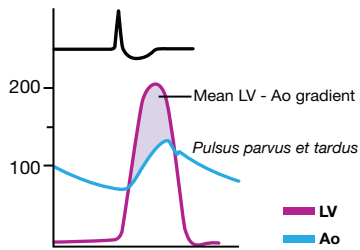
CONGENITAL AORTIC STENOSIS (can be treated by balloon valvuloplasty)

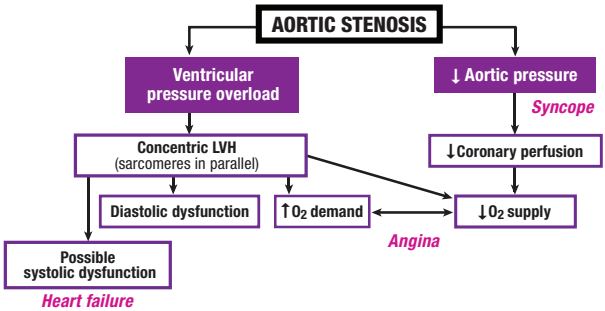
RHEUMATOID AORTIC STENOSIS (rare)

DDx: Aortic sclerosis (calcification but **peak velocity < 2.5 m/s)**; HCM (dynamic obstruction)

- **Supravalvular aortic stenosis: strong A2**; murmur radiates to the right carotid; BP right arm > BP left arm; associated with Williams syndrome
- **Subvalvular aortic stenosis**: membrane or tunnel; combined with AR; absence of systolic anterior motion (SAM) of mitral leaflet

HEMODYNAMIC CONSEQUENCES





SYSTOLIC DYSFUNCTION SECONDARY TO:

1) ↘ **Intrinsic contractility** secondary to remodeling (only slight improvement with surgery)
2) **Mismatch between high afterload and insufficient concentric LVH** (afterload mismatch) (improved by surgery)

SEVERITY

NORMAL AREA: 3-4 cm^2

	MILD	MODERATE	SEVERE	CRITICAL
Jet velocity (m/s)	2.6-2.9	3.0 - 4.0	> 4.0	> 5.0
Mean gradient (mmHg)	< 20	20 - 40	> 40	> 60
Valve area (cm^2)	> 1.5	1.0 - 1.5	< 1.0	< 0.6
Indexed valve area (cm^2/m^2)	> 0.85	0.6 - 0.85	< 0.6	
LVOT VTI / Ao valve VTI ratio	> 0.50	0.25 - 0.50	< 0.25	

SYMPTOMS AND SIGNS

SYMPTOMS: **Heart failure / Dyspnea; Angina; Syncope**

› Bleeding (destruction of von Willebrand factor; Heyde's syndrome)

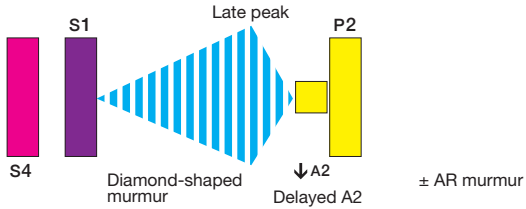
CAROTID: ***pulsus parvus* et *tardus*** (slow ascent; late peak; low amplitude) (absent in the presence of arteriosclerosis); carotid thrill

APEX: sustained; lateralized if LV dysfunction; S4 sometimes palpable; **apical-carotid delay**

AORTIC AREA: look for **thrill**

AUSCULTATION: **crescendo - decrescendo murmur with late peak**; carotid radiation; radiation to apex in the case of Gallavardin phenomenon (high-pitched murmur); accentuation of murmur post-PVC; decrescendo diastolic murmur in the presence of associated AR

› **S2 with a single component: Inaudible A2** or delayed A2 and at same time as P2 with paradoxical expiratory splitting
› **S4**
› **Systolic ejection click** of bicuspid aortic valve disappears in the case of ↘ valve mobility



INVESTIGATIONS

STRESS TEST: To distinguish asymptomatic from symptomatic aortic stenosis; contraindicated if the patient presents symptoms of AS

› Look for symptoms - decreased exercise capacity (< 80% predicted) - abnormal BP response (↗ SBP < 20 mmHg)

ECHOCARDIOGRAPHIC FOLLOW-UP

MILD AS	MODERATE AS	SEVERE ASYMPTOMATIC AS
TTE every 3 to 5 years	TTE every 1 to 2 years	TTE every 6 months to 1 year

HEMODYNAMIC ASSESSMENT - INDICATIONS

a) Inconclusive noninvasive investigation
b) Discordance between clinical findings and noninvasive investigation

PREOPERATIVE CORONARY ANGIOGRAPHY - INDICATIONS

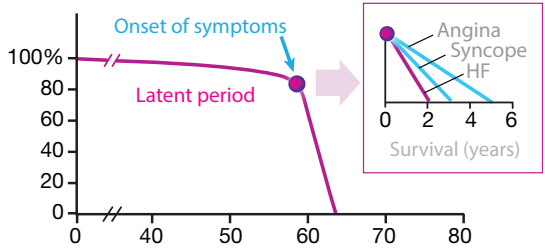
› Angina; documented ischemia; LV systolic dysfunction; known CAD; Male > 40 years; postmenopause; cardiovascular risk factors
- Consider coronary CT angiography in patients with low-to-moderate pretest probability of CAD
- It is reasonable not to perform preoperative coronary angiography in a surgical emergency in the presence of acute valvular regurgitation, acute aortic syndrome or bacterial endocarditis (class IIa recommendation)

OUTCOME

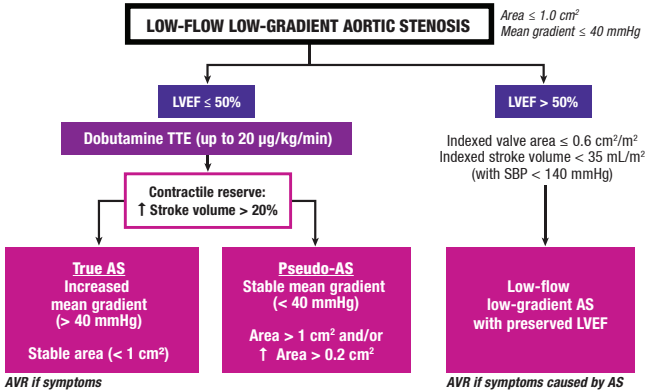
↘ Valve area by 0.1 cm² / year; ↗ Mean gradient by 7 mmHg / year

Asymptomatic AS: risk of sudden death < 1% / year

Symptomatic AS: ↘ survival (sudden death); **2 years in the presence of HF; 3 years in the presence of syncope; 5 years in the presence of angina**



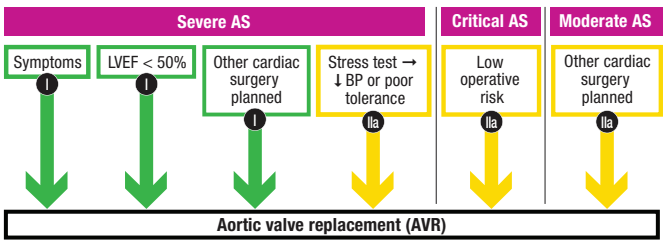
LOW-FLOW LOW-GRADIENT AORTIC STENOSIS



MANAGEMENT

MEDICAL: Patient education - report all symptoms; avoid strenuous physical exertion; echocardiographic follow-up; low-dose diuretics; avoid BB; cautious use of vasodilators (fixed obstruction); treatment of cardiovascular risk factors

SURGERY - INDICATIONS



› **Complication of AVR**: mortality 1-3%; stroke 2%; prolonged ventilation 11%; thromboembolism; bleeding; prosthetic dysfunction

PERCUTANEOUS BALLOON VALVULOPLASTY

Risk of major complications > 10%

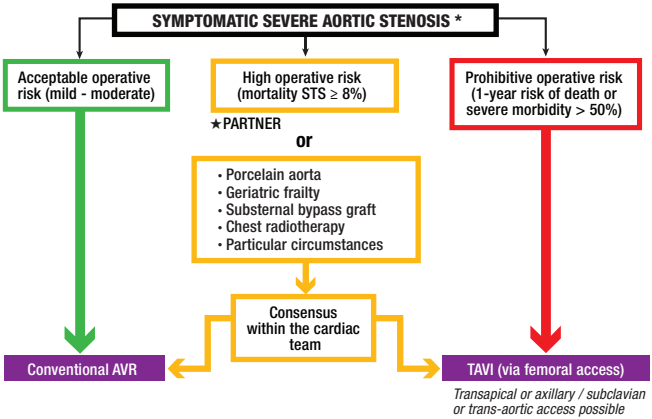
Recurrent symptoms and restenosis at 6 months

Does not constitute a medium-term or long-term alternative to AVR or TAVI

LIMITED INDICATIONS: bridge to AVR or TAVI in a patient with severe symptoms

› Effective in adolescents / young adults with congenital AS in the absence of calcification

TAVI (Transcatheter aortic valve implantation)



* Absence of futility: an operation will probably improve life span and/or quality of life; survival with treatment will probably be ≥ 1-2 years

PRE-TAVI ASSESSMENT: **A)** TTE; **B)** TEE: aortic annulus dimensions at insertion of leaflets on anteroposterior view (PLAX) and side-to-side (short-axis); **C)** CT angiography: Ao; aortic annulus dimensions; aortic-iliac-femoral PAD; distance between coronary ostia and aortic annulus; **D)** Coronary angiography - Aortography - Ventriculography

- Aortic annulus diameter: **> 18 mm and < 29 mm**
- Coronary ostia - aortic annulus distance **≥ 10-11 mm**
- Femoral vascular access: **femoral artery diameter > 6 mm** (to accommodate a 7 mm catheter); evaluate the degree of calcification and arterial tortuosities
- **Geriatric frailty:** increased risk of adverse events during major surgery; **5-meter walking time > 6 s**; Katz index of independence in ADL

STEPS OF THE FEMORAL APPROACH: **A)** Femoral access; **B)** Transvalvular guide; **C)** Delivery catheter; **D)** Pre-dilatation by valvuloplasty during rapid ventricular pacing (180-200 bpm); **E)** Positioning of the valve under fluoroscopic / angiographic guidance and/or by TEE (50% above and 50% below the plane of the aortic annulus); **F)** Valve deployment during rapid ventricular pacing (180-200 bpm) (Sapien valve); **G)** Identification and management of complications; **H)** Closure of access site

LIMITED BENEFIT OF TAVI: Life expectancy < 1 year; 2-year survival with estimated benefit < 25%; STS > 15% (no benefit on survival in ★ PARTNER B); advanced geriatric frailty (dependence for multiple ADL); multiple comorbidities

COMPLICATIONS: 30-day mortality: 3-5%; stroke (6-7%); vascular complications (17%); valve embolization; coronary occlusion (due to migration of a leaflet or calcification); mitral valve disease; perivalvular regurgitation (incomplete apposition); tamponade; AV block requiring PPM (2-9% Sapien; 19-43% Corevalve); arrhythmias; bleeding; aortic rupture

POST-TAVI MANAGEMENT: Long-term ASA; Thienopyridine for 1 to 6 months (except when treated with warfarin); prophylactic antibiotics; annual clinical and TTE follow-up

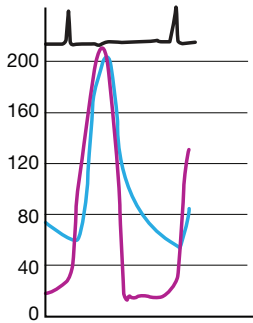
4.2/ CHRONIC AORTIC REGURGITATION

ETIOLOGIES

VALVULAR: **A)** Degenerative (calcification); **B)** Endocarditis; **C)** Leaflet prolapse (loss of support due to aortopathy); **D)** Bicuspid aortic valve; **E)** Rheumatic; **F)** VSD; **G)** Subaortic membrane; **H)** Iatrogenic (post-balloon valvuloplasty); **I)** Myxomatous proliferation; **J)** SLE - RA - ankylosing spondylitis

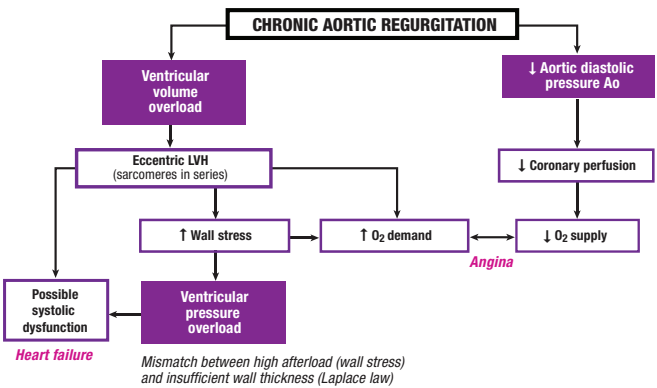
AORTIC: **A)** Aortic dilatation: degenerative / cystic medial necrosis (isolated; Marfan; bicuspid aortic valve); osteogenesis imperfecta; syphilis; Behçet; Takayasu; giant cell arteritis; spondyloarthropathies / ankylosing spondylitis / psoriatic arthritis; polychondritis; HTN; **B)** Dissection: leaflet prolapse following loss of support or presence of intravalvular flap or leaflet perforation by dissection; **C)** Traumatic

HEMODYNAMIC CONSEQUENCES



- Normal or ↑ LVEDP (↑ ↑ ↑ if acute AR)
- ↑ Aortic systolic pressure
- ↓ Aortic diastolic pressure
- ↑ **Pulse pressure**
- ± Pulsus bisferiens
- Femoral systolic pressure > 20 mmHg higher than aortic systolic pressure

LV
Ao



Mismatch between high afterload (wall stress) and insufficient wall thickness (Laplace law)

SEVERITY

	MILD AR (1/4)	MODERATE AR (2 to 3/4)	SEVERE AR (4/4)
Vena contracta (mm)	< 3	3 - 5.9	≥ 6
Regurgitant volume (mL/b)	< 30	2/4: 30 - 44 3/4: 45 - 59	≥ 60
Regurgitant fraction (%)	< 30	30 - 49	≥ 50
Regurgitant orifice (cm²)	< 0.10	2/4: 0.1 - 0.19 3/4: 0.2 - 0.29	≥ 0.30
Jet width (PLAX)	Central; < 25% of LVOT	Intermediate	> 65% of LVOT
Area of regurgitant jet (PSAX)	< 5 % of LVOT area	Intermediate	> 60 % of LVOT area
Pressure half-time (ms)	> 500	200-500	< 200
Diastolic reversal of descending Ao	Brief; Early diastolic	Intermediate	Holodiastolic and prominent (end-diastolic velocity > 20 cm/s)
LV dimensions	Normal		Dilatation
Angiography	1+	2+	3-4+

OTHER MARKERS OF SEVERITY: Holodiastolic reversal of flow in proximal abdominal aorta

SYMPTOMS AND SIGNS

SYMPTOMS: Heart failure - Dyspnea; Angina; Tiredness

- Poorly tolerated bradycardia (↗ regurgitation time)

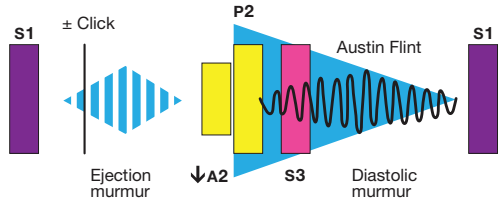
VITAL SIGNS: **↗ pulse pressure (with ↘ DBP)**

PULSE: bounding; ***pulsus bisferiens*** (more accurately assessed in brachial or femoral arteries); carotid thrill (↗ stroke volume)

APEX: large; hyperdynamic; lateralized; ± palpable S3

AUSCULTATION: **decrescendo diastolic murmur starting at A2**; more accurately assessed with the patient seated and leaning forward in forced expiration; duration correlated with severity

- Murmur increases with fists clenched
- **Radiation to left parasternal region indicates a valvular etiology; Radiation to right parasternal region indicates an aortic etiology**
- **Decreased A2** indicates a valvular etiology
- Systolic ejection click (abrupt distension of the aorta)
- **S3**
- **Systolic ejection murmur** (↗ stroke volume) ± thrill
- **Austin Flint murmur**: diastolic rumbling due to aortic reflux onto anterior mitral leaflet
- **Distinguish AR from PR**: AR → murmur starting at A2; peripheral signs; PR murmur ↗ during inspiration

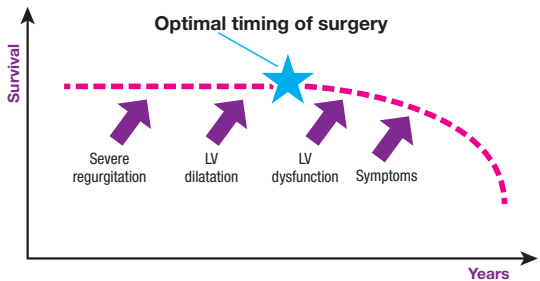


Musset's sign	Systolic nodding of the head
Müller's sign	Systolic pulsation of uvula
Quincke's sign	Capillary pulsation (by pressing lightly on the tip of the nail)
Corrigan's pulse / Water hammer pulse	Abrupt distension with prominent pulse then rapid collapse (more accurately assessed in the radial artery with the arms raised)
Traube's sign (pistol shot)	Systolic and diastolic bruit in the femoral artery
Duroziez' sign	Systolic murmur in the femoral artery with proximal compression and diastolic murmur with distal compression (from the stethoscope)
Hill's sign	SBP in arms > 20 mmHg higher than SBP in legs

OUTCOME AND FOLLOW-UP

Survival rate declines markedly in the presence of symptoms or LV dysfunction

› **Mortality in the presence of symptoms**: > 10 % / year

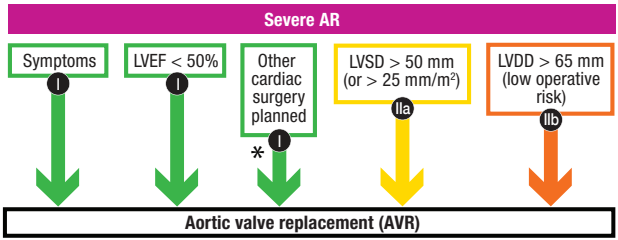


NEWLY DIAGNOSED AR	MILD AR	MODERATE AR	SEVERE AR	SEVERE AR WITH LV DILATATION
TTE at 3 months to ensure stability	TTE every 3 to 5 years	TTE every 1 to 2 years	TTE every 6 to 12 months	TTE every 4 to 6 months

MANAGEMENT

MEDICAL: patient education - report all symptoms; avoid strenuous physical exertion / isometric exercises; echocardiographic follow-up; treat diastolic HTN (ACE inhibitors or Nifedipine); avoid bradycardia; ACE inhibitors and beta-blockers if poor candidate for surgery with severe AR with symptoms and/or LV dysfunction

SURGERY: AVR vs AVR + ascending aorta replacement (Bentall) vs Valve repair vs Ascending aorta replacement + valvular resuspension (David procedure) vs Ross procedure



* IIa if moderate AR

4.3/ ACUTE AORTIC REGURGITATION

ETIOLOGIES: **A)** Endocarditis; **B)** Aortic dissection; **C)** Trauma; **D)** Prosthetic valve dysfunction

HEMODYNAMIC CONSEQUENCES: Regurgitant volume in poorly compliant LV → ↗↗ diastolic pressures → Congestive heart failure

- ↘ Anterograde flow → Systemic hypoperfusion / Shock
- Early mitral valve closure (restrictive diastolic filling pattern)

PHYSICAL EXAMINATION: Tachycardia; shock; pulmonary edema

- ↘ S1 (early mitral valve closure); S3 and S4
- **Brief diastolic murmur** (early pressure equalization on either side of the valve)
- **Austin Flint rumble**
- Systolic murmur (↗ stroke volume)
- Signs of PHT

MANAGEMENT: Urgent surgery

- Positive inotropic agent (Dobutamine) and/or vasodilator (Nitroprusside)

4.4/ MITRAL STENOSIS

ETIOLOGY

RHEUMATIC FEVER: Leading cause of MS

- 25% of patients have isolated MS; 40% have MS and MR; 35% have concomitant aortic valve disease; 6% have concomitant tricuspid valve disease

OTHER RARE CAUSES: **A)** Congenital; **B)** Carcinoid with lung metastases or PFO; **C)** SLE; **D)** RA; **E)** Hunter-Hurler; **F)** Fabry; **G)** Whipple; **H)** Methysergide; **I)** Calcific MS (age related)

DDX (LV INFLOW OBSTRUCTION): LA tumor - Myxoma; LA thrombus; Obstructive vegetation; Cor triatriatum; Severe mitral annular calcification (age); Pulmonary vein stenosis

SEVERITY

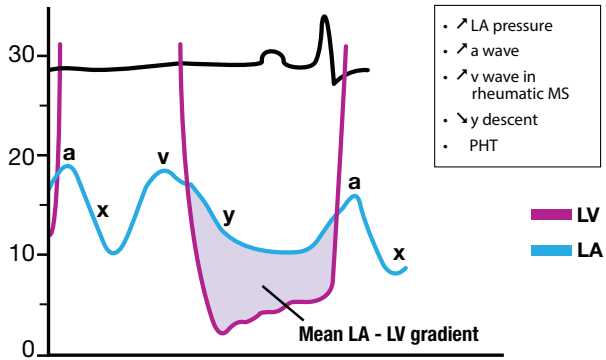
NORMAL AREA: 4-5 cm²

	MILD	MODERATE	SEVERE
Valve area (cm²)	> 1.5	1.0 - 1.5	< 1.0
Mean gradient (mmHg)	< 5	5 - 10	> 10
sPAP (mmHg)	< 30	30 - 50	> 50
Pressure half-time (ms)		150 - 220	> 220 ms

Indices valid for heart rate between 60 and 90 bpm

HEMODYNAMIC CONSEQUENCES

- ↗ LA pressure → pulmonary congestion / PHT / Right heart failure
- LA dilatation → risk of AF / atrial stasis / peripheral embolism
- Intolerance of tachycardia or loss of atrial kick
- Low output state



SYMPTOMS AND SIGNS

SYMPTOMS: Dyspnea; tiredness; poor exercise tolerance; OTP; PND

- **PHT**: Right heart failure; hemoptysis (rupture of bronchial veins; rupture of capillaries; pulmonary edema)
- Palpitations; peripheral embolism
- Recurrent laryngeal nerve compression by dilated LA (Ortner's syndrome)

MITRAL FACIES: secondary to systemic vasoconstriction; pink-purple plaques on cheeks

JUGULAR: JVD; prominent a wave (sinus rhythm)

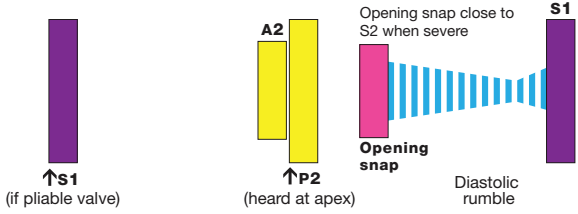
AUSCULTATION: ↗ **S1** when leaflets still pliable and only slightly calcified

OPENING SNAP: Heard more clearly with the diaphragm; absent during significant leaflet calcification

› **A2 - opening snap interval inversely proportional to the severity of MS (severe if < 80 ms)**

DIASTOLIC RUMBLE: Heard more clearly in left lateral supine position with the bell at the apex; look for thrill; murmur increased during tachycardia - exercise

SIGNS OF PHT: **left parasternal heave; P2 increased** (± palpable); ejection click (PA dilatation); TR murmur; Graham Steell murmur; right S3-S4



INVESTIGATIONS AND OUTCOME

TTE: Rheumatic MS → thickening ± calcification of leaflets; hockey stick appearance of anterior mitral leaflet; LA dilatation; commissural fusion with "fish-mouth" mitral orifice (PSAX)

ECHOCARDIOGRAPHIC FOLLOW-UP

MILD MS	MODERATE MS	SEVERE MS
TTE every 3 to 5 years	TTE every 1 to 2 years	TTE annually

STRESS TEST: Evaluate exercise capacity and symptoms

› Combined with TTE to evaluate PAP and mean gradient on exertion when there is a discordance between symptoms and TTE at rest

OUTCOME: **Valve area ↘ by 0.09 cm²/year**

› 5-year survival in patients with symptomatic severe MS without intervention: 44%

MANAGEMENT

MEDICAL: prevention of recurrence of rheumatic fever (penicillin-based prophylactic antibiotics); avoid strenuous exertion; follow-up and decision to operate at the optimal time; aggressive treatment of AF and thromboembolic risk; diuretics PRN; avoid tachycardia

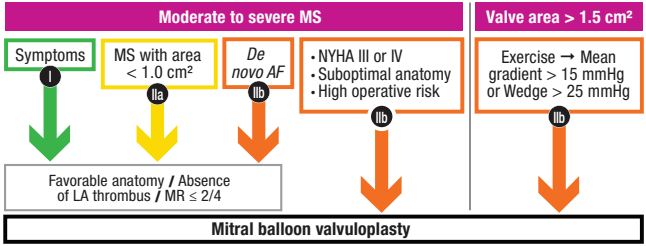
› **Indication for anticoagulation**: **AF; Cardioembolic history; LA thrombus**

BALLOON MITRAL VALVULOPLASTY: transseptal approach; TEE guidance; Inoue 23 to 25 mm balloon; inflation of the balloon inside the valve orifice in order to open commissures

› **Better results in a context of favorable anatomy**: **Wilkins score (BVR) ≤ 8 points**
  - **Success**: valve area > 1.5 cm² and LA pressure < 18 mmHg

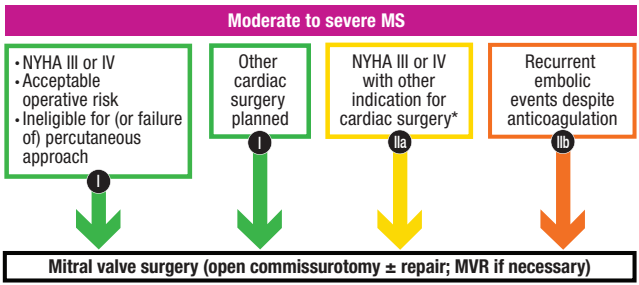
› **Contraindications: moderate to severe MR; LA thrombus (pre-procedure TEE); unfavorable anatomy**

› **Complications**: mortality 1%; stroke - embolism 1-2%; cardiac perforation 1%; MR requiring surgery 2%; iatrogenic ASD; myocardial infarction < 1%



SURGICAL APPROACH: **A)** Closed commissurotomy (obsolete approach); **B)** Open commissurotomy ± mitral valve repair (under CPB); **C)** MVR

› Consider MAZE and LAA amputation during surgery (★ CTSN AF)



* TR; CAD; aortic valve disease; aortic aneurysm, etc.

4.5/ CHRONIC MITRAL REGURGITATION

ETIOLOGY

DEGENERATIVE: **MVP - Myxomatous disease**; Marfan; Ehlers-Danlos; Pseudoxanthoma elasticum; Mitral annular calcification

INFLAMMATORY: **Rheumatic disease**; SLE; Scleroderma; Hypereosinophilia syndrome

INFECTIOUS: Endocarditis

STRUCTURAL: **Ruptured chordae tendineae** (spontaneous - idiopathic; MI; trauma; MVP; endocarditis; rheumatic fever; acute LV dilatation)

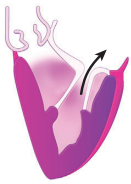
CONGENITAL: Cleft mitral valve; parachute mitral valve (absence of mitral papillary muscle)

FUNCTIONAL MR: associated with LV dysfunction / LV dilatation; **structurally normal valve;** + MR secondary to: **A)** Mitral papillary muscle displacement (malcoaptation of leaflets; tenting area > 6 cm² associated with MR ≥ 3/4; **B)** Annular dilatation; **C)** Loss of the annular systolic contraction; **D)** ± Mitral papillary muscle dysfunction in the presence of concomitant ischemia

› **Ischemic papillary muscle dysfunction**: **posteromedial muscle (perfusion by PDA)** +
>> anterolateral muscle (double perfusion by diagonal and marginal arteries)

CARPENTIER'S CLASSIFICATION

According to movement of the leaflets

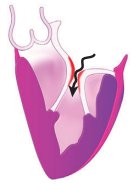


NORMAL MOVEMENT

Endocarditis
Trauma
Annular dilatation

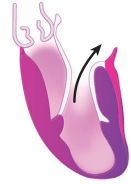
↑ **MOVEMENT**

MVP
Ruptured chordae tendineae



SYSTOLO-DIASTOLIC RESTRICTION

Rheumatic



SYSTOLIC RESTRICTION

Papillary muscle dysfunction

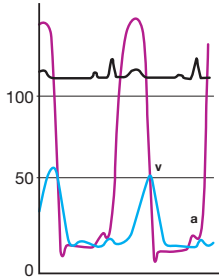
Displaced papillary muscle secondary to RWMA / LV dilatation

SEVERITY

	MILD MR (1/4)	MODERATE MR (2 to 3/4)	SEVERE MR (4/4)
Veina contracta (mm)	< 3	3 - 6.9	≥ 7
Regurgitant volume (mL/b)	< 30	2/4: 30 - 44 3/4: 45 - 59	≥ 60
Regurgitant fraction (%)	< 30	30 - 49	≥ 50
Regurgitant orifice (cm^2) (prognostic value)	< 0.20	2/4: 0.2 - 0.29 3/4: 0.3 - 0.39	≥ 0.40
Jet area	Small central jet < 4 cm^2 or < 20% of LA area	Intermediate	Large central jet > 10 cm^2 (or > 40% of LA area) or eccentric jet along the LA wall (Coanda)
Pulmonary vein flow rate	Systolic dominance	Systolic attenuation	Systolic reversal
Jet envelope on continuous Doppler	Faint; parabolic	Intermediate	Dense; Early, triangular peak
LA dimensions	Normal		Dilatation
LV dimensions	Normal		Dilatation
Angiography	1+	2+	3-4+

FUNCTIONAL MR: severe regurgitation when regurgitant orifice ≥ 0.20 cm^2 or regurgitant volume ≥ 30 mL/b or regurgitant fraction ≥ 50%

HEMODYNAMIC CONSEQUENCES



- **Prominent v wave** (≥ 2-3 x mean LA pressure) except in the presence of significant LA dilatation
- Prominent y descent
- PAP contaminated by v wave
- ± LA-LV diastolic flow gradient

CHRONIC MITRAL REGURGITATION

→ **↓ Anterograde volume** → *Tiredness*

Tolerated for a long time due to low afterload (the LA is a low pressure safety valve) → **Ventricular volume overload** → **Eccentric LVH** (sarcomeres in series) → **Possible systolic dysfunction** → *Heart failure*

- Annular dilatation
- Papillary muscle displacement

LA dilatation → *AF*

↑ LA pressure and Possibly ↑ PAP

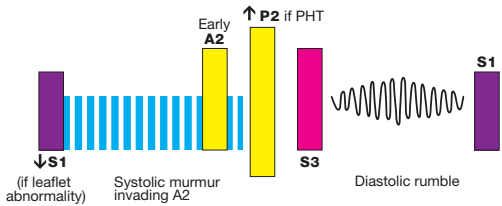
SYMPTOMS AND SIGNS

SYMPTOMS: Dyspnea; OTP; PND; symptoms of low output state; Palpitations (AF); Right heart failure

APEX : hyperdynamic; **dilated; lateralized**; ± palpable S3; palpable wave in left parasternal region (dilated LA kick)

AUSCULTATION : **Decreased S1** in the presence of a leaflet abnormality; early A2 and split S2; P2 > A2 in the presence of PHT; S3; diastolic rumble (↗ inflow)

SYSTOLIC MURMUR: spreads as far as (and invades) A2; **often holosystolic**; ± thrill; high-pitched; maximum at the apex; radiation to the axilla or left scapula (posteriorly directed murmur) or sternum and base (anteriorly directed murmur as in posterior leaflet MVP); not amplified post-PVC; decreased by standing up (increased by squatting); decreased during Valsalva; increased by clenching the fists (in contrast with aortic stenosis)



DDx: **A)** VSD: murmur maximal in left parasternal region; thrill in left parasternal region; **B)** TR: murmur ↗ on inspiration; murmur maximal in left parasternal region; prominent jugular v wave

ISCHEMIC PAPILLARY MUSCLE DYSFUNCTION: mid-systolic or end-systolic murmur

ECHOCARDIOGRAPHIC FOLLOW-UP

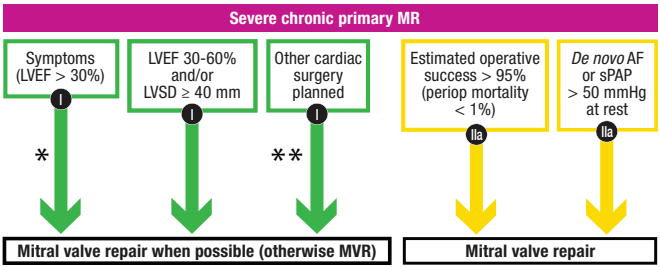
MILD MR	MODERATE MR	SEVERE MR
TTE every 3 to 5 years	TTE every 1 to 2 years	TTE 6 to 12 months

TEE to clarify the anatomy, mechanism, severity and possibility of repair

Stress echocardiography PRN to detect ischemic MR and to measure PAP on exertion

MANAGEMENT

MEDICAL: **little benefit of vasoactive agents in the presence of normal LVEF** (afterload is rarely increased except in HTN); anticoagulation in the presence of AF; aggressive treatment of LV dysfunction in the presence of functional MR (+ resynchronization)



IIb: Consider Mitraclip when surgery is contraindicated in NYHA III or IV with favorable anatomy

*IIb: Symptoms and LVEF < 30% ** IIa: Moderate chronic primary MR (mitral valve repair)

MITRAL VALVE REPAIR / ANNULOPLASTY: Best candidates (in the absence of calcification) → **A)** Degenerative MR - MVP (posterior leaflet easier to repair); **B)** Annular dilatation; **C)** Papillary muscle dysfunction; **D)** Ruptured chordae tendineae; **E)** Leaflet perforation (endocarditis)

- Possible via a minimally invasive approach
- Warfarin for 3 months post-repair; ASA 80 indefinitely

MVR: opt for preservation of the subvalvular apparatus whenever possible (LVEF ↘ by 10% if loss of the subvalvular apparatus due to modification of LV geometry)

MITRACLIP: percutaneous transseptal repair; creation of a double orifice valve using a clip (equivalent to Alfieri procedure)

- ★ **EVEREST**: Mitraclip less effective than conventional surgery to reduce the degree of regurgitation
- **Candidates**: inoperable patient; mitral regurgitation with **regurgitant jet due to malcoaptation of segments A2 and P2**; functional or degenerative regurgitation (MVP or leaflet eversion); depth of coaptation < 11 mm; vertical length of coaptation > 2 mm

FUNCTIONAL MR: ▸▸| Chapter 3

MITRAL VALVE PROLAPSE

2.4% of the population; female predominance

DIAGNOSIS: **A)** Mid-systolic click then murmur; **B) Displacement of one or both leaflets > 2 mm behind the plane of the mitral annulus (PLAX); C) ± Thickening of the leaflets by > 5 mm**

ETIOLOGIES

a) **MVP syndrome**: young woman; benign; associated with OH - palpitations - anxiety; thin leaflets
b) **MVP with myxomatous thickening**: often males aged 40-70 years; thickening / redundancy of the leaflets; significant risk of progression; risk of ruptured chordae tendineae
c) **MVP associated with another disease**: Marfan; HCM; Ehlers-Danlos; osteogenesis imperfecta; *pseudoxanthoma elasticum;* Holt-Oram syndrome; *ostium secundum* ASD; Ebstein's anomaly

CLINICAL FEATURES: **mid-systolic click** then mid- or end-systolic murmur (often crescendo); normal S1; dynamic auscultation

› Mid-systolic click different from the aortic ejection click, as it occurs after the onset of the carotid upstroke

DECREASED LEFT INTRAVENTRICULAR VOLUME	INCREASED LEFT INTRAVENTRICULAR VOLUME
Effect: ↗ duration of MVP murmur  	Effect: ↘ duration of MVP murmur Maneuvers: • Tachycardia • ↘ Afterload • ↗ Contractility • ↘ Venous return (standing; Valsalva)	**Maneuvers:** • Bradycardia • ↗ Afterload (clenched fists) • ↘ Contractility • ↗ Venous return (squatting; raising legs)

COMPLICATIONS: Heart failure; Ruptured chordae tendineae; Thromboembolism; Endocarditis; AF; serious complications (including surgery) in 1/100 patient-years

› **TIA**: ASA 80 mg qd
› **AF**: anticoagulation if > 65 years or HTN or MR or history of heart failure
› **Stroke**: anticoagulation if MR or AF or LA thrombus or leaflets > 5 mm

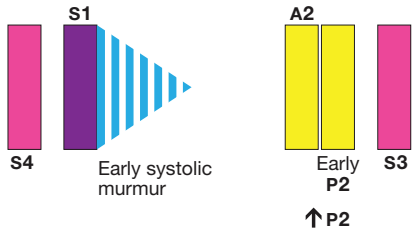
4.6/ ACUTE MITRAL REGURGITATION

ETIOLOGIES: **A)** Endocarditis; **B)** Trauma - Iatrogenic; **C)** Ruptured chordae tendineae (idiopathic-spontaneous; myxomatous degeneration / MVP; Marfan; Ehlers-Danlos; endocarditis; acute rheumatic fever; trauma); **D)** Papillary muscle dysfunction or rupture (ischemia - MI); **E)** Prosthetic valve dysfunction

HEMODYNAMIC CONSEQUENCES: Acute MR → poorly compliant LA (significant v wave) → pulmonary congestion / PHT

› Acute MR → low anterograde flow

PHYSICAL EXAMINATION: **Decrescendo early systolic murmur** due to rapid equalization of pressures on both sides of the valve; **S3 and S4**; signs of PHT; early closure of pulmonary valve (early P2); pulmonary overload; hypotension; tachycardia



MANAGEMENT: Urgent surgery in the presence of heart failure

› **Medical treatment**: Nitroprusside (± Dobutamine) while waiting for surgery; IABP

4.7/ TRICUSPID STENOSIS

ETIOLOGIES: **Rheumatic** (majority); usually associated with MS

› **Other causes (rare)**: Congenital atresia; RA tumor; Carcinoid syndrome (TR >> TS); PPM lead; Extracardiac tumor; Thrombus; Endomyocardial fibrosis; Endocarditis; SLE

SEVERITY: Significant TS when valve area ≤ 1 cm^2 or mean gradient ≥ 5 mmHg or pressure halftime > 190 ms

JUGULAR: Prominent a wave; Loss of y descent

AUSCULTATION: diastolic rumble in lower left parasternal region with ↗ on **inspiration** (± thrill); murmur ↗ on **Mueller maneuver** (inspiration against closed glottis) or during exercise

› Opening snap following that of MS in lower left parasternal region
› Diastolic rumble of the MS; Opening snap

SIGNS OF RIGHT HEART FAILURE (ascites; HSM; peripheral edema; JVD)

MANAGEMENT: operation if **severe symptomatic TS or severe TS with concomitant mitral surgery**

› Open commissurotomy vs TVR (bioprosthesis) vs Balloon valvuloplasty

4.8/ TRICUSPID REGURGITATION

ETIOLOGIES: **Secondary / Functional** (majority); secondary to dilatation of the tricuspid annulus following dilatation of the RV (sPAP > 55 mmHg; RV infarction; PS; DCM; left heart failure...)

› **Primary causes**: Rheumatic; Endocarditis; Ebstein's anomaly; Prolapse (associated with MVP); Carcinoid; Papillary muscle dysfunction / Ruptured chordae tendineae; Trauma; Marfan; RA; Radiotherapy; AV canal defect; Endomyocardial fibrosis; Myxoma; PPM lead; Repeated biopsy (heart transplant); anorectics; SLE

SEVERITY

	MILD TR (1/4)	MODERATE TR (2 – 3/4)	SEVERE TR (4/4)
Jet area (central) cm²	< 5	5 - 10	> 10
Vena contracta (mm)			≥ 7
PISA radius (mm)	≤ 5	6 - 9	> 9
Tricuspid E (m/sec)			> 1
Jet envelope on continuous Doppler	Faint; parabolic	Intermediate	Dense; Early, triangular peak
Hepatic vein flow	Systolic dominance	Systolic attenuation	Systolic reversal

› **Other criteria**: tricuspid annulus ≥ 40 mm (or > 21 mm/m²); D-shaped septal curvature; RV - RA dilatation; EROA ≥ 0.4 cm²; regurgitant volume ≥ 45 mL/b

INSPECTION: Cachexia; Jaundice; Pulsatile orbits

JUGULAR: Prominent c-v wave; loss of x descent; prominent y descent; ± venous thrill; Kussmaul

PALPATION: left parasternal heave; RV lift

AUSCULTATION: **Right S3** (↗ on inspiration); ↗ P2 if PHT; holosystolic murmur in lower left parasternal region (early systolic if primary TR); murmur ↗ on inspiration (Carvallo's sign); **murmur ↗ on Mueller's maneuver**

SIGNS OF RIGHT HEART FAILURE (ascites; pulsatile liver; HSM; peripheral edema; JVD)

MANAGEMENT - SECONDARY TR: Tricuspid annuloplasty during mitral surgery in the presence of: **A)** Severe TR or **B)** Mild-to-moderate TR with dilatation of the tricuspid annulus (≥ 40 mm) or in the presence of PHT or right heart failure

MANAGEMENT - PRIMARY TR: Bioprosthesis TVR or Annuloplasty if severe symptomatic TR or severe TR with progressive RV dilatation / dysfunction or severe TR with concomitant mitral surgery

› **TR secondary to endocarditis in IDU**: total excision of the valve is possible
› **Carcinoid syndrome**: ▶▶| Chapter 5 - RCM

4.9/ PULMONARY STENOSIS

▶▶| Chapter 7 - Congenital heart disease

ETIOLOGIES: Congenital (majority)

› **Fusion of commissures**: thin, dome-shaped valve; treatment by balloon valvuloplasty
› **Dysplastic valve**: thickened leaflets; Noonan syndrome; surgical treatment

OTHER ETIOLOGIES (RARE): Carcinoid; extrinsic compression (tumor; aortic sinus aneurysm); Rheumatic; Supravalvular or subvalvular obstruction (congenital)

SEVERITY: Severe PS if peak gradient > 64 mmHg

4.10/ PULMONARY REGURGITATION

ETIOLOGIES: **A)** Annular dilatation or dilatation of PA (PHT); **B)** Endocarditis; **C)** Following correction of congenital PS - TOF; **D)** Congenital; **E)** Trauma; **F)** Carcinoid; **G)** Rheumatic; **H)** Syphilis

SEVERITY

	MILD PR (1/4)	MODERATE PR (2 TO 3/4)	SEVERE PR (4/4)
Jet envelope on continuous Doppler	Faint; Slow deceleration	Intermediate	Dense; Marked deceleration; early end of diastolic flow (± anterograde diastolic flow)

› **Other criteria**: D-shaped septal curvature; RV dilatation; PHT < 100 ms

PALPATION: left parasternal heave; systolic beat in the 2nd intercostal space (PA dilatation)

AUSCULTATION: Delayed P2; systolic click (PA dilatation); mid-systolic ejection murmur (↗ flow); right S3 and S4 (increased on inspiration)

› **Diastolic murmur:** soft, low-pitched (in the absence of PHT); ↗ on inspiration
› **Graham Steell murmur**: decrescendo high-pitched diastolic murmur in the presence of dilatation of the pulmonary annulus secondary to PHT; accentuated P2; starts after A2; ↗ on inspiration; signs of PHT; TR murmur

4.11/ MULTIVALVULAR HEART DISEASE

AS & MS: Aortic transvalvular gradient underestimated (low flow)

AS & MR: MR increased due to high left intraventricular pressure; the aortic transvalvular gradient can be underestimated (low flow); operate on the mitral valve when MR is severe or in the presence of significant mitral structural disease

AR & MR: MR accentuates AR causing more severe pulmonary congestion; severe LV dilatation (accentuating MR)

4.12/ VALVE PROSTHESES

MECHANICAL PROSTHESES	BIOPROSTHESES
• High thrombo-embolic risk • Excellent durability • **Prefer in patients < 60 years**	• Risk of structural deterioration (Mitral >> Aortic) - Decreased risk in patients > 65 years • **Prefer in the presence of: A) Bleeding risk; B) Difficult anticoagulation; C) > 70 years; D) Small LVOT (stentless bioprosthesis); E) Woman of childbearing potential; F) Patient preference**
• Double-leaflet (St-Jude; Carbo-Medics; ATS Medical) • Tilting-disk (Medtronic-Hall; Omnicarbon)	• Stented porcine bioprosthesis (Mosaic) • Stented bovine pericardium bioprosthesis (Carpentier-Edwards; Mitroflow) • Stentless bioprosthesis - Less obstructive; prefer in patients with small LVOT • Homograft: cadaveric valve - Used for complex aortic valve endocarditis • Ross procedure: autologous transplant of the patient's P valve to the Ao valve; use a cadaveric valve for the P valve - Use in young patients / women of childbearing potential • Percutaneous bioprosthesis (TAVI): - Deployed by balloon (Edwards-Sapien; Sapien XT) - Self-expanding bioprosthesis (Corevalve)

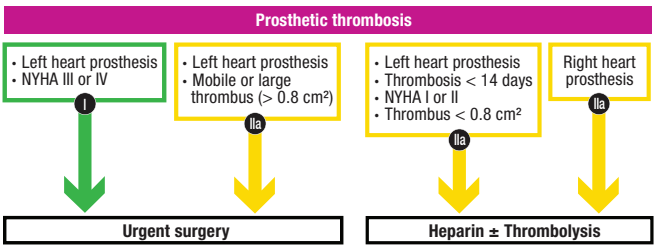
COMPLICATIONS: **A)** Structural deterioration; **B)** Pannus; **C)** Patient-prosthesis mismatch (▸▸| Chapter 1 - Echocardiography); **D)** Thrombosis; **E)** Embolism; **F)** Endocarditis (vegetation; abscess; fistula; dehiscence; destruction); **G)** Periprosthetic leak; **H)** Hemolysis related to periprosthetic regurgitation (↗ LDH; ↗ Bilirubin; ↘ Haptoglobin; Schistocytes); **I)** Dehiscence (rule out endocarditis); **J)** Bleeding secondary to anticoagulants; **K)** Pseudoaneurysm

- **Structural deterioration**: TAVI is possible (valve-in-valve)
- **Periprosthetic regurgitation**: Percutaneous closure with Amplatzer prosthesis (with 3D TEE guidance); indicated if the patient is not a candidate for surgery with significant periprosthetic regurgitation and secondary heart failure or hemolysis (transfusion-dependent); transseptal or transapical approach (M valve); retrograde arterial approach (Ao valve)

MECHANICAL VALVE: thromboembolic risk ⟶ 1-2 per 100 patient-years (aortic) and 2-3 per 100 patient-years (mitral)

PORCINE BIOPROSTHESIS: **structural deterioration** in 30% of patients at 10 years
- 10% at 10 years in patients > 65 years

PROSTHETIC THROMBOSIS: dyspnea; ↘ closing sound; *de novo* murmur
- **Diagnosis**: TTE - TEE - Fluoroscopy
- **Risk**: 0.1%/ year for aortic valve; 0.35%/year for mitral valve (with adequate treatment)



rtPA 10 mg bolus then 90 mg IV over 120 min
Mortality: 4-12% / Embolism: 15%

ANTITHROMBOTIC THERAPY

MITRAL VALVE REPAIR / ANNULOPLASTY	
• Warfarin for 3 months (INR 2-3) • ASA 80 mg qd indefinitely	
BIOPROSTHESIS	
• ASA 80 mg qd indefinitely • ± Warfarin 3 months postoperatively (INR 2-3); Class IIa recommendation for bioprosthesis MVR; • Class IIb recommendation for bioprosthesis AVR	
MECHANICAL PROSTHESIS (MODERN)	
Low risk **AVR with no risk factors*** • Warfarin indefinitely (INR 2-3) • ASA 80 mg qd indefinitely	**High risk** **AVR with risk factors* or MVR** • Warfarin indefinitely (INR 2.5-3.5) • ASA 80 mg qd indefinitely

*** Risk factors: AF / LV dysfunction / History of thromboembolic disease / Hypercoagulability**

EMBOLISM DESPITE WARFARIN THERAPY: **A)** If INR 2-3 → target INR 2.5-3.5; **B)** If INR 2.5-3.5 → target INR 3.0-4.0; **C)** If patient not taking ASA → add ASA

EXCESSIVE ANTICOAGULATION: **A)** Life-threatening bleeding → Prothrombin complex concentrate (or FFP) + vitamin K 5-10 mg IV (max: 1 mg/min); **B)** INR > 10 without bleeding → suspend Warfarin; vitamin K 2.5 mg PO

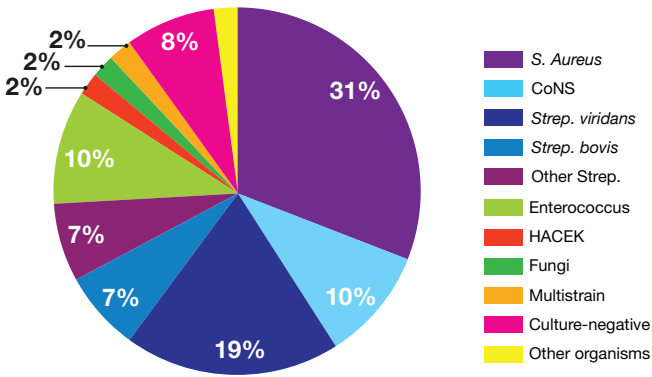
FOLLOW-UP

BIOPROSTHESIS	MECHANICAL VALVE
• Baseline TTE to 2-4 weeks after discharge • Annual follow-up (± TTE if new symptoms and signs) • After 10 years: annual TTE	• Baseline TTE to 2-4 weeks after discharge • Annual follow-up (± TTE if new symptoms and signs)

AT FOLLOW-UP: Physical examination; ECG; CXR; ± Laboratory tests (CBC; BUN / Creatinine; Clotting assessment; INR; Blood cultures); Prophylactic antibiotics

4.13/ INFECTIVE ENDOCARDITIS

MICROBIOLOGY



Culture-negative:

Previous antibiotic; *Coxiella burnetii; Bartonella sp.; Aspergillus sp.; Mycoplasma pneumonia; Brucella sp.; Legionella pneumophila; Tropheryma whipplei; Bartonella sp.;* Fungi (*Candida sp.; Aspergillus sp.*); Antiphospholipid syndrome; Marantic endocarditis; Porcine bioprosthesis allergic response; Rheumatic carditis; Polyarteritis nodosa...

***S.aureus* (including MRSA)**	• Aggressive acute endocarditis; marked toxicity • Metastatic infection; valve destruction • Mortality 25-40% (left heart)
Coagulase-negative Staphylococcus - CoNS ***(S. epidermidis; S. lugdunensis)***	• Foreign body infection / prostheses • Nosocomial infection
Streptococcus viridans (sanguis; mutans; mitis; salivarius...)	• Oropharyngeal flora; alpha-hemolytic • **Subacute endocarditis** • Highly sensitive to penicillin
Streptococcus bovis (gallolyticus)	• GI flora; associated with polyps and colon cancer • **Subacute endocarditis** • Highly sensitive to penicillin
Beta-hemolytic Streptococci (groups A - B - C - G)	• Frequent intracardiac and extracardiac complications; abscess
Enterococci (*faecalis* and *faecium*)	• GI flora • Associated with urinary tract infection/nosocomial infection • Treatment requires bactericidal activity **(synergism with gentamicin)**
HACEK • ***Haemophilus sp.*** • ***Aggregatibacter sp. (previously Actinobacillus)*** • ***Cardiobacterium hominis*** • ***Eikenella corrodens*** • ***Kingella sp.***	• Fastidious Gram-negative bacilli • Upper respiratory tract infections - Oropharyngeal flora • Positive blood culture after 5 days of incubation (sometimes longer) • Large vegetation
Other micro-organisms (can cause culture-negative endocarditis)	• ***Coxiella burnetii* (Q fever)**: subacute endocarditis; elevated IgG titer • ***Bartonella sp.***: Culture-negative endocarditis (perform serology or specific culture technique); cat scratch disease • **Fungi *(Candida)*:** Risk factors: immunodepression - prosthesis - central line - IDU; invasive endocarditis • **Others**: *Brucella sp.; Tropheryma whipplei; Mycoplasma sp.; Legionella sp.*

RISK FACTORS

RISK FACTORS: MVP; congenital heart disease (bicuspid aortic valve; VSD; patent ductus arteriosus); rheumatic disease; degenerative valvular heart disease; IDU; prosthesis or intracardiac device; hospitalization - nursing home; central line; hemodialysis; history of endocarditis

IDU (INJECTION DRUG USERS): *S.aureus* (most frequent organism); mostly involving the tricuspid valve (look for septic pulmonary emboli)

PROSTHETIC VALVE ENDOCARDITIS (PVE)

- **Early (< 12 months post-op): CoNS; *S. aureus*; Gram-negative bacilli; Fungi *(Candida); Corynebacterium* sp; *Legionella* sp**
- **Late (> 12 months post-op): similar microbiology to community-acquired native valve endocarditis**
- Mortality due to *S. aureus* PVE: > 45%

MODIFIED DUKE CRITERIA

DEFINITE ENDOCARDITIS	POSSIBLE ENDOCARDITIS
• 2 major criteria or • 1 major + 3 minor criteria or • 5 minor criteria	• 1 major + 1 minor or • 3 minor criteria

MAJOR CRITERIA

1. Positive blood culture

A) Typical microorganism on ≥ 2 separate blood cultures
- *Strep. viridans; Strep. bovis;* HACEK*; S.areus* or
- Community-acquired Enterococcus with no primary site

B) Sustained bacteremia
- **Slow method**: ≥ 2 positive blood cultures taken at an interval of ≥ 12 h or
- **Rapid method**: 3/3 positive blood cultures or the majority of ≥ 4 blood cultures are positive (taken by different venipunctures); the first and last cultures were taken at an interval of > 1 h

C) *Coxiella burnetii* (Q fever): ≥ 1 positive culture bottle or IgG titer > 1:800

2. Endocardial involvement

A) Positive echocardiography
- Oscillating intracardiac mass (on valve or supporting structures, or in the path of regurgitant jets, or on foreign body) in the absence of an alternative explanation or
- Abscess or
- *De novo* prosthetic dehiscence

B) *De novo* valvular regurgitation

Minor criteria

1. **Predisposition** (heart disease or IDU)
2. **Fever** ≥ 38°C
3. **Vascular phenomenon**: arterial embolism; septic pulmonary infarction; mycotic aneurysm; intracranial hemorrhage; conjunctival hemorrhage; Janeway lesion
4. **Immunological phenomenon** (subacute endocarditis): glomerulonephritis; Osler's nodes; Roth's spot; positive rheumatoid factor; vasculitis
5. **Microbiological evidence**: positive blood culture but not meeting the major criterion or serological evidence of active infection (with organism consistent with infective endocarditis)

Li JS, Sexton DJ, Mick N, et al. Clin Infect Dis 2000;30:633

SYMPTOMS AND SIGNS

SYMPTOMS: fever; chills; night sweats; weight loss; dyspnea; cough; stroke; headache; nausea / vomiting; myalgia; arthralgia; retrosternal chest pain; back pain; abdominal pain; confusion

SIGNS: fever; neurological signs; signs of peripheral embolism; clubbing

- **Cardiac murmur**: in 85% of cases (uncommon in subacute endocarditis)
- **Splinter hemorrhages**: proximal nail fold; red lines
- **Petechiae**: conjunctiva; oral mucosa and palate; extremities
- **Osler's nodes**: small, painful subcutaneous nodule on fingertips (sometimes more proximal)
- **Janeway lesion**: painless, erythematous or hemorrhagic macular lesion on palms and soles
- **Roth's spot**: oval retinal hemorrhage (with central pallor)
- **Splenomegaly**: more frequent in subacute endocarditis

COMPLICATIONS

PERIPHERAL EMBOLISM

- **Risk factors**: vegetation > 10 mm / mobile; mitral valve (anterior leaflet); *S.aureus; Candida*
- **Uncommon after 2 weeks of effective treatment**
- Stroke; digital infarction; septic arthritis; discitis; splenic or renal infarction; splenic abscess; coronary embolism; mesenteric embolism; pulmonary embolism

STROKE: **A) Cardioembolic; B) Intracranial hemorrhage**: ruptured mycotic aneurysm or arteritis with rupture or hemorrhagic transformation of a stroke

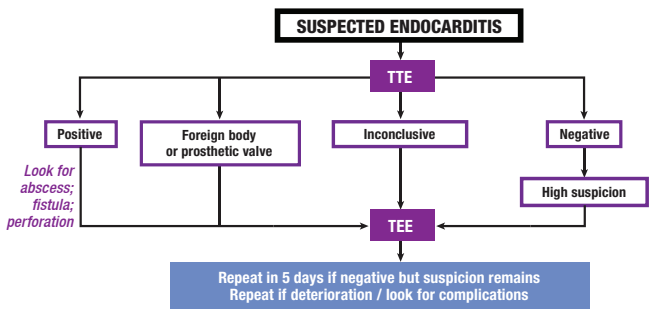
- **Dx**: **A) MRI angiography or CT angiography; B) Conventional angiography** to exclude small aneurysms (< 2 mm) not seen on non-invasive imaging
- **Indication for intervention:** progressing or ruptured aneurysm or > 7 mm
  - **Small aneurysm without rupture**: monitor (possible improvement with antibiotics)
- **When valve surgery is indicated: A) Stroke without bleeding → surgery without delay** (except with extensive brain damage / coma); **B) Intracranial bleeding → wait > 4 weeks**
- **Management of anticoagulation:** stop anticoagulation in patients with mechanical valve > 2 weeks in the presence of stroke (class IIa recommendation)

HEART FAILURE: A) Valve destruction; **B)** Ruptured chordae tendineae; **C)** Fistula; **D)** Purulent myocarditis; **E)** Coronary embolism; **F)** Valve obstruction

ARF: **A)** Immune complex glomerulonephritis (↘ complement); **B)** Renal embolism (renal infarction); **C)** Prerenal ARF; **D)** Gentamicin toxicity; **E)** Interstitial nephritis (secondary to antibiotics)

AV BLOCK / CONDUCTION DISORDERS: perivalvular abscess

ECHOCARDIOGRAPHY



SENSITIVITY: TTE → 70% (50% for prosthesis); **TEE →** 96% (92% for prosthesis)

VEGETATION: Oscillating mass with independent movement; atrial aspect for M and T valves; ventricular aspect for Ao and P valves; on the surface of implanted intracardiac material

- **DDx**: Old vegetation; Non-bacterial thrombotic endocarditis (marantic); Antiphospholipid syndrome / SLE (Libman-Sacks); degenerative changes / myxomatous valve; Lambl's excrescences; ruptured chordae tendineae; Ca^{2+}; nodule - RA; thrombus; fibroelastoma

LOOK FOR: **vegetation; abscess** (not communicating with the lumen) **/ pseudoaneurysm** (pulsatile; colour-Doppler flow detected); **prosthetic dehiscence** (± rocking motion); valvular aneurysm (saccular bulging); intracardiac fistula; valve perforation - channel; purulent pericarditis; obstruction; early mitral valve closure in acute AR (with restrictive diastolic pattern)

MANAGEMENT

ANTIBIOTIC TREATMENT: Target → eradication of microorganisms; bactericidal antibiotic action; sufficient serum concentrations (to penetrate the vegetation by diffusion); minimal toxicity

- **MIC**: Minimum inhibitory concentration (to inhibit growth)
- **MBC**: Minimum bactericidal concentration (to reduce the inoculum)

DURATION: from the first day on which blood cultures ar negatives

- **Positive operative tissue cultures**: entire antimicrobial course after valve surgery

PNC-SENSITIVE *STREP. VIRIDANS* OR *STREP. BOVIS* - MIC < 0.12 µG/ML		
PNC G	12-18 million U / day IV (4-6 doses)	4 weeks
Ceftriaxone	2 g / day IV or IM (1 dose)	4 weeks
PNC G (or Ceftriaxone) + Gentamicin	12-18 million U / day IV (4-6 doses) 3 mg/kg / day IV or IM (1 dose)	2 weeks 2 weeks
Vancomycin	30 mg/kg / day IV (2 doses)	4 weeks

- **Prosthesis: A)** 6 weeks therapy of PNC G (24 million U / day) or Ceftriaxone (with or without gentamicin for the first 2 weeks); **B)** 6 weeks therapy of Vancomycin
- Serum Vancomycin levels: trough 10-15 µg/mL
- Serum Gentamicin levels (3 divided doses): peak serum 3-4 µg/mL; trough < 1 µg/mL

STREP. VIRIDANS OR *STREP. BOVIS* RELATIVELY RESISTANT - MIC 0.12 – 0.50 µG/ML		
PNC G + Gentamicin	24 million U / day IV (4-6 doses) 3 mg/kg / day IV or IM (1 dose)	4 weeks 2 weeks
Vancomycin	30 mg/kg / day IV (2 doses)	4 weeks

- **Prosthesis**: 6 weeks therapy
- Ceftriaxone: consider as an alternative if the isolate is susceptible

METHICILLIN-SENSITIVE STAPHYLOCOCCUS - NO FOREIGN BODY		
Cloxacillin	12 g / day IV (4-6 doses)	6 weeks
Cefazolin	6 g / day IV (3 doses)	6 weeks
Vancomycin (ß-lactam allergy evaluation)	30 mg/kg / day IV (2 doses)	6 weeks

- Uncomplicated right heart endocarditis: 2 weeks

METHICILLIN-RESISTANT STAPHYLOCOCCUS - NO FOREIGN BODY		
Vancomycin	30 mg/kg / day IV (2 doses)	6 weeks
Daptomycin	≥ 8 mg/kg / day IV (1 dose)	6 weeks
METHICILLIN-SENSITIVE STAPHYLOCOCCUS - PROSTHESIS		
Cloxacillin + Rifampicin + Gentamicin	12 g / day IV (4-6 doses) 900 mg / day IV or PO (3 doses) 3 mg/kg / day IV or IM (2-3 doses)	≥ 6 weeks ≥ 6 weeks 2 weeks
METHICILLIN-RESISTANT STAPHYLOCOCCUS - PROSTHESIS		
Vancomycin + Rifampicin + Gentamicin	30 mg/kg / day IV (2 doses) 900 mg / day IV or PO (3 doses) 3 mg/kg / day IV or IM (2-3 doses)	≥ 6 weeks ≥ 6 weeks 2 weeks

- Rifampin: caution in relation to multiple drug interactions

ENTEROCOCCUS SPP.		
Ampicillin + Gentamicin	2 g IV every 4 h 3 mg/kg / day IV or IM (2-3 doses)	4-6* weeks 2-6 weeks (6 weeks with prosthetic valve)
Ampicillin + Ceftriaxone *(E. faecalis)*	2 g IV every 4 h 4 g / day IV or IM (2 doses)	6 weeks 6 weeks
Vancomycin + Gentamicin	30 mg/kg / day IV (2 doses) 3 mg/kg / day IV or IM (3 doses)	6 weeks 6 weeks

* 4 weeks with < 3 months duration of symptoms (6 weeks with ≥ 3 months)

HACEK		
Ceftriaxone	2 g / day IV or IM (1 dose)	4 weeks (6 weeks if prosthesis)

EMPIRICAL TREATMENT (BEFORE PATHOGEN IDENTIFICATION) – COMMUNITY–ACQUIRED NATIVE VALVE OR LATE PROSTHETIC VALVE (> 12 MONTHS)	
Ampicillin + Cloxacillin + Gentamicin	2 g IV every 4 h 12 g / day IV (4-6 doses) 3 mg/kg / day IV or IM
EMPIRICAL TREATMENT (BEFORE PATHOGEN IDENTIFICATION) – EARLY PROSTHETIC VALVE (< 12 MONTHS) OR NOSOCOMIAL ENDOCARDITIS	
Vancomycin + Gentamicin + Rifampin	30 mg/kg / day IV (2 doses) 3 mg/kg / day IV or IM 900 mg / day IV or PO (3 doses)

PROPHYLACTIC ANTIBIOTICS

Candidates

a) Prosthetic valve (or prosthetic valve material)
b) History of infective endocarditis
c) Congenital heart disease
1. Unrepaired cyanotic heart disease (including palliative conduits and shunts)
2. Complete repair with prosthetic material < 6 months
3. Repair with residual defect close to prosthesis / patch (preventing endothelialization)

d) Transplant recipient with regurgitation on a structurally abnormal valve

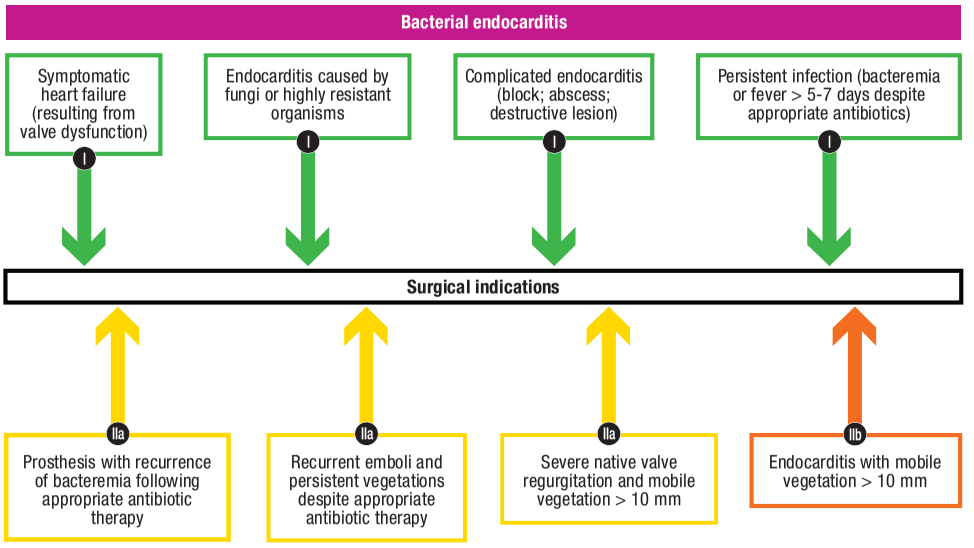
Procedure

- Dental procedure involving the gums or periapical region of the tooth or perforation of the oral mucosa

- **Amoxicillin 2 g PO** (60 min before the operation) or
- Cephalexin 2 g PO or Azithromycin 500 mg PO or Clindamycin 600 mg PO or
- Cefazolin or Ceftriaxone 1 g IM or IV

SURGICAL INDICATIONS

- Coronary CT angiography can provide coronary artery evaluation before cardiac surgery



I: Removal of implantable cardiac device (pacemaker or ICD) if documented infection of the system
IIa: Removal of implantable cardiac device (pacemaker or ICD) if endocarditis due to *S.aureus* or fungi

4.14/ CARDIAC IMPLANTABLE ELECTRONIC DEVICE INFECTION

MICROBIOLOGY: CoNS (42%); Sensitive *S. aureus* (25%); MRSA (4%); Gram-negative bacilli (9%); Multistrain (7%); Culture-negative (7%)

PATHOGENESIS

A) Pocket infection (during procedure or secondary to skin erosion) → ± propagation of infection to intravascular leads → ± intracardiac propagation of infection

B) Bacteremia *(S. aureus)* → hematogenous pocket and/or lead infection

ASSESSMENT: blood cultures x 2; TEE if blood cultures positive (rule out vegetation adherent to the lead and/or the valve); culture of the pocket after explantation of the system; FDG PET-CT (rule out increased FDG uptake)

MANAGEMENT

A) Superficial skin infection without involvement of the pocket and system → oral antibiotics against Staphylococcus for 7 to 10 days

B) Pocket infection and/or skin erosion: complete removal of the system (even in absence of systemic infection) + ATB

C) Documented system infection (lead endocarditis and/or valve endocarditis and/or bacteremia with pocket involvement): complete removal of the system + ATB (risk of clinically significant pulmonary embolism during percutaneous lead removal if vegetation on electrode > 2 cm)

D) Valve endocarditis (without documented system infection): complete removal of the system (± implantation of a new epicardial system) + ATB

E) Occult Staphylococcus bacteremia: complete removal of the system + ATB

EMPIRICAL ANTIBIOTICS: Vancomycin (then according to the organism / sensitivity)

DURATION OF ANTIBIOTICS: **A)** 7-10 days if skin erosion with no inflammatory changes; **B)** 10-14 days if pocket infection; **C)** > 2-4 weeks IV if bacteremia (repeat TEE in 2 weeks in the case of lead vegetation); **D)** > 4-6 weeks if complication (valve endocarditis; septic thrombophlebitis; osteomyelitis)

OPTIMAL TIMING FOR PLACEMENT OF A NEW DEVICE (CONTRALATERAL): **A)** Skin erosion / Pocket infection: in the absence of bacteremia; **B)** Positive blood cultures: absence of bacteremia x > 72 h post-explantation; **C)** Valve endocarditis: wait > 14 days before reimplanting an endovenous system

TEMPORARY PACEMAKER: Use active fixation lead

4.15/ RHEUMATIC FEVER

Autoimmune reaction 2 to 4 weeks after group A beta-hemolytic Streptococcus sore throat *(S. pyogenes)*

JONES' CRITERIA

Major criteria
1) Carditis and valvulitis
2) Migratory arthritis (swollen joints)
3) Sydenham's chorea (CNS inflammation; late manifestation)
4) Erythema marginatum (trunk; proximal limbs)
5) Subcutaneous nodules

Minor criteria
- Arthralgia
- Fever
- Elevation of inflammatory markers (ESR - CRP)
- Prolonged PR

Diagnosis: group A Streptococcal sore throat followed by:
- 2 major criteria or
- 1 major criterion + 2 minor criteria

CARDITIS

PANCARDITIS: **Valvulitis (MR >> AR)**; LV dysfunction; pericarditis

PHYSICAL EXAMINATION (IN A CONTEXT OF ACUTE RHEUMATIC FEVER):
Tachycardia; ↘ S1; ↗ P2 in the case of severe MR; S3; holosystolic murmur; **Carey Coombs murmur** (mid-diastolic murmur secondary to turbulence and increased mitral diastolic flow); early diastolic decrescendo murmur in the case of AR; pericardial friction rub; TR murmur

LONG-TERM SEQUELAE: **Progressive mitral valve disease (MS >> MR)** which becomes symptomatic after several decades; Ao or T valve involvement is possible

PRIMARY PREVENTION

Start antibiotics < 10 days after onset of sore throat

PNC V 500 mg PO bid for 10 days

SECONDARY PREVENTION

Candidate	Agent	Duration
All patients with history of rheumatic fever (with or without carditis) due to the high risk of recurrence (class I recommendation)	• PNC G 1.2 million U IM every 4 weeks (or every 3 weeks if residual cardiac lesion) or • PNC V 200 mg PO bid or • Sulfadiazine 1 g PO daily	• Persistent valvular heart disease: > 10 years since last episode (until age of 40 years minimum; long term if in contact with children) • History of carditis but no sequelae: > 10 years since episode (until age of 21 years minimum) • Absence of carditis: > 5 years since episode (until age of 21 years minimum)

5.1/ DISEASES OF THE PERICARDIUM: ETIOLOGIES

IDIOPATHIC (MOST COMMON)

INFECTIOUS

- **Viral:** echovirus; coxsackievirus; adenovirus; EBV; CMV; HCV; HIV; influenza; parvovirus B19
- **Bacterial**: Pneumococcus; Staphylococcus; Streptococcus; Mycoplasma; Lyme; *Haemophilus influenzae;* Meningococcus; Gonococcus; *Coxiella burnetii; Legionella* spp*; Listeria* spp
- **Mycobacteria**: *M. tuberculosis; M. avium*
- **Fungi**: histoplasmosis; coccidioidomycosis
- **Parasites**: toxoplasmosis; echinococcosis
- **Infective endocarditis** (extension)

INFLAMMATORY - IMMUNE

- **Collagen diseases**: SLE; RA; Scleroderma; Sjögren
- **Vasculitis**: PAN; Giant cell arteritis; Churg-Strauss; Takayasu; Behçet
- Sarcoidosis
- Still disease
- **Dressler's syndrome**: late post MI or late post-cardiac surgery or late post-trauma
- Myopericarditis
- Inflammatory bowel disease
- Acute rheumatic fever (pancarditis)
- **Medications:** Procainamide; Hydralazine; Cyclosporine; Doxorubicin; Cyclophosphamide...

NEOPLASTIC

- **Primary:** mesothelioma; angiosarcoma; lipoma; paraganglioma
- **Secondary:** Lung; Breast; Lymphoma; Kaposi sarcoma; GI carcinoma; melanoma; sarcoma...

RADIOTHERAPY

EARLY POST-MYOCARDIAL INFARCTION (2-4 DAYS)

EARLY POST-CARDIAC SURGERY

HEMOPERICARDIUM

- Trauma
- Free wall rupture (infarction)
- Aortic dissection
- **Iatrogenic**: PCI; pacemaker; ablation of arrhythmia; ASD closure; valve repair / replacement; endomyocardial biopsy

TRAUMA

- Contusion; Penetrating injury; Post-CPR

CONGENITAL

- Cyst
- Congenital absence of pericardium

OTHER

- Renal failure - Uremia
- Dialysis
- Anorexia nervosa
- Chylopericardium
- Hypothyroidism or Hyperthyroidism
- Amyloidosis
- Heart failure (transudate)
- Severe PHT (transudate)
- Familial Mediterranean fever; TRAPS syndrome

EARLY POST-MI PERICARDITIS (< 1 WEEK): extension of transmural necrosis to the pericardium (with localized pericarditis); **localized ST elevation; look for ventricular rupture** if effusion associated; treatment with ASA 650 mg PO qid at tapered doses (avoid other NSAIDs) + Colchicine

DRESSLER'S SYNDROME: Late post-MI or post-cardiac surgery or post-trauma pericarditis; **autoimmune phenomenon**; polyserositis; fever; treatment with NSAID + Colchicine

RADIATION-INDUCED PERICARDITIS: A) Acute; B) Late: several months to several years; pericarditis - effusion - constriction - effusion / constriction

METASTATIC PERICARDIAL EFFUSION: Management → pericardiocentesis with drainage; intrapericardial chemotherapy or sclerosing agent; radiotherapy; pericardial window (surgical via left minithoracotomy or percutaneous approach)

CHRONIC PERICARDIAL EFFUSION: Look for and treat an underlying cause; look for systemic inflammation (CRP); **when idiopathic** → monitor by regular TTE **vs.** trial of NSAID / colchicine **vs.** pericardiocentesis (if chronic and > 20 mm; if symptomatic; if suspicion of bacterial or neoplastic aetiology)

DIALYSIS-ASSOCIATED PERICARDITIS: Now more frequent than uremic pericarditis; occurs even with normal plasma urea; consider intensifying dialysis

BACTERIAL PERICARDITIS: Direct extension of pneumonia or endocarditis or hematogenous spread or iatrogenic; **toxic patient;** urgent pericardiocentesis / urgent surgical drainage (± pericardiotomy; ± pericardiectomy)

5.2/ ACUTE PERICARDITIS

Inflammation of the pericardium

Dry vs serous vs fibrinous pericarditis (fibrin; granulation; adhesions; scarring) vs suppurative (bacterial) vs hemorrhagic

PRESENTATION: Retrosternal chest pain **(pleuritic; radiation to trapezius; worse in supine position; relieved by sitting foward)**; dyspnea

CLINICAL FEATURES: ± fever; ± tachycardia; ± signs of tamponade

- **Pericardial friction rub**: **1 or 2 or 3 components (systole; rapid ventricular filling; atrial kick);** evanescent; left parasternal region; patient seated, leaning forward in forced expiration +

ECG: 4 phases

1. **Diffuse ST elevation (concave); PR segment depression; mirror changes in aVR**
2. Normalization of ST segment with depression of the J point
3. T wave inversion
4. T wave normalization

ASSESSMENT: ECG; TTE; Creatinine - BUN; CBC; liver tests; CXR; ESR - CRP; Troponin (if ↗: consider myopericarditis or MI)

- ± ANA; ANCA; RF; PPD; HIV; HCV; TSH; BNP; tumor work-up; chest CT scan and/or cardiac MRI; Ferritin (Still disease); ACE (Sarcoidosis); Serology for *Coxiella burnetii* or for Lyme disease
- ± Pericardial aspiration (looking for cancer cells - cytology; cultures / mycobacterium culture; PCR for TB; Adenosine deaminase); Biopsy (cancer; TB)

DIAGNOSIS: **Clinical diagnosis: ≥ 2 out of 4 criteria**

Pleuritic and positional retrosternal chest pain	Pericardial friction rub (pathognomonic)	Typical ECG changes	Pericardial effusion

MANAGEMENT

IBUPROFEN **600 to 800 mg every 6 to 8 h** > **10 to 14 days (with tapering based on clinical response)**

/or

ASA 650 mg PO qid

⊕

PPI daily

⊕

COLCHICINE **0.5 mg bid for 3 months if > 70 kg (0.5 mg daily if < 70 kg)**

(★ COPE and ★ ICAP studies)

- Look for and treat any specific cause
- Analgesia - Narcotics PRN
- Rest / avoid exercise until complete resolution of symptoms (athletes: 3 months)
- **Corticosteroids: not recommended as first-line therapy**, as risk factor for recurrence
- **Hospitalization: A)** Fever; **B)** Subacute course; **C)** Failure to respond within 7 d to NSAID; **D)** Large pericardial effusion (> 20 mm) and/or tamponade; **E)** Myopericarditis; **F)** Trauma; **G)** Underlying cause; **H)** Immunosuppression; **I)** Receiving anticoagulant

COMPLICATIONS: pericardial effusion; tamponade; constriction

5.3/ INCESSANT AND RECURRENT PERICARDITIS

INCESSANT PERICARDITIS: recurrence of symptoms on withdrawal of treatment

RECURRENT PERICARDITIS: new episode after a symptom-free interval of > 4-6 weeks

- "Self-reactivity" sometimes develops following the first episode

MANAGEMENT

1. **Rule out a specific cause**
2. Resume NSAID with tapering over > 12 weeks; assess the response to therapy with CRP
3. Colchicine (★ CORP; ★ CORP-2) for ≥ 6 months
4. Avoid corticosteroids (in case of contraindications to ASA / NSAID / Colchicine → Prednisone 0.2-0.5 mg/kg daily for several weeks then gradual tapering)
5. **Last resort**: Azathioprine; IV immunoglobulins; anti-IL-1 (e.g. Anakira); Pericardiectomy

5.4/ CARDIAC TAMPONADE

THE PERICARDIUM is a closed sac with a low volume reserve; accumulation of fluid induces increased intrapericardial pressure and **compression of the heart chambers** (R > L)

- **Normal volume of pericardial fluid**: < 50 mL

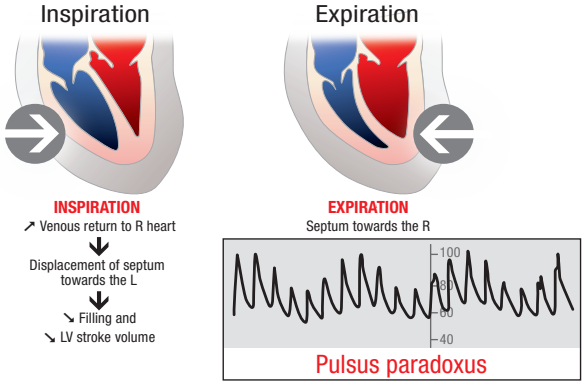
Increase then equalization of diastolic pressures in heart chambers ≈ INTRAPERICARDIAL PRESSURE ≈ 15-20 mmHg

CLINICAL FEATURES: tachypnea; tachycardia; diaphoresis; signs of hypoperfusion

- **Beck's triad**: **hypotension; muffled heart sounds; JVD**
- **Jugular: attenuated y descent**

PULSUS PARADOXUS: ↘ > 10 mmHg of SBP on inspiration

- Difference between the two pressures on sphygmomanometry when:
  1. Onset of Korotkoff sounds (expiration only)
  2. Korotkoff sounds are audible throughout the respiratory cycle
- **Pathophysiology:** cardiac transmission of respiratory variations of intrathoracic pressure is maintained



- **Tamponade and absence of pulsus paradoxus**: AR; ASD; severe LV dysfunction; LVH; RVH; severe hypotension; pericardial adhesions; localized effusion
- **DDx of pulsus paradoxus:** constrictive pericarditis (effusion-constriction); pulmonary embolism; RV infarction; pulmonary disease with marked variations of intrathoracic pressure (asthma; COPD; OSAHS); obesity; ascites; severe hypotension / hemorrhage; pectus excavatum

ECG: low voltage; electrical alternans

CXR: rounded and enlarged heart shadow

FLUOROSCOPY: abolition of cardiac pulsation

TTE: pericardial effusion (anterior to aorta on PLAX); **RA collapse during its relaxation** after the peak of the R wave (very sensitive and specific if > 1/3 of cardiac cycle); **early diastolic RV collapse after T wave** (absent if RVH); abnormal respiratory movement of the septum; plethoric IVC

- **Exaggerated respiratory variations of transvalvular flow**
  - Measure the first E wave following the start of inspiration and expiration
  - **Mitral valve**: **↘ E on inspiration; variation > 30% (Eexp - Einsp / Eexp)**
  - **Tricuspid valve**: **↘ E on expiration; variation > 60% (Exp - Einsp / Eexp)**

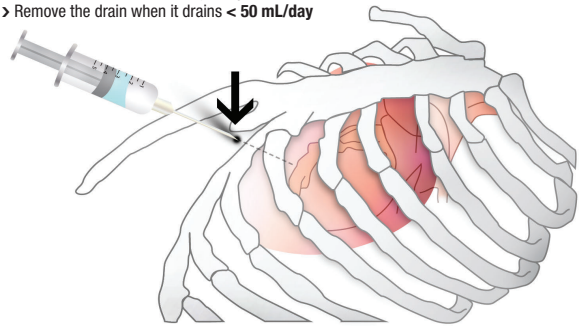
- **Pulmonary veins:** predominance of **systolic** flow (↘ Y wave)
- **Hepatic veins**: **expiration** → ↘ anterograde flow and ↗ diastolic reversal (A wave)

	TAMPONADE	CONSTRICTION
Pulsus paradoxus	Present	Possible (1/3)
Jugular	Attenuation of Y wave	Prominent Y wave "M or W" Pattern
Effect of inspiration on CVP	Reduction (normal effect)	Kussmaul (increase or absence of reduction)

	TAMPONADE	CONSTRICTION
Equalization of diastolic pressures	+	+
Square root sign (ventricular curve)	Absent	+
Ventricular interdependence (discordance of RV and LV systolic pressures during breathing)	Present	Present
Valve flow variations	• M valve: ↘ E on inspiration; **variation > 30 %** • T valve: ↘ E on expiration; **variation > 60 %**	• M valve: ↘ E on inspiration; **variation > 25 %** • T valve: ↘ E on expiration; **variation > 40 %**
Pulmonary vein flow	Systolic	Diastolic
Hepatic vein flow	↗ Diastolic reversal on expiration	↗ Diastolic reversal on expiration

PERICARDIOCENTESIS

1. Patient in 45° supine; subxiphoid approach (1 cm below the xyphoid process and 1 cm to the patient's left); local anesthesia
2. Needle introduced at an angle of 30-45° to the skin aiming for the left scapula while applying negative pressure on the syringe (± echocardiographic guidance)
3. Confirm the correct position of the needle: contrast in the case of echocardiographic guidance; insertion of a guide into the pericardial sac in the case of fluoroscopic guidance
4. Insertion of a dilator followed by a Pigtail catheter
   - › Remove the drain when it drains **< 50 mL/day**



- › **Indications: A)** Tamponade; **B)** Diagnosis of pericardial effusion (metastases; bacterial pericarditis; TB)
- › **Contraindication**: Aortic dissection with hemopericardium; ventricular rupture; coagulopathy; inaccessible effusion
- › **Complications (1-2%)**: Perforation of right heart chambers; coronary laceration; pneumothorax; hepatic puncture; arrhythmia; arterial bleeding
- › **Surgical drainage**: Following trauma or ventricular rupture or loculated / organized effusion or when biopsy is required or bacterial pericarditis
- › **Pericardial window (pericardiotomy)**: During reaccumulation / frequent recurrence; surgical or balloon

5.5/ CONSTRICTIVE PERICARDITIS

Pericardial fibrosis / calcification / adhesions

ETIOLOGIES: Idiopathic; Postoperative; Viral pericarditis; Recurrent pericarditis; Post-radiotherapy; TB; Other (infectious; neoplastic; collagen disease; uremia; post-trauma; sarcoidosis)

CONSEQUENCE: limited filling of heart chambers

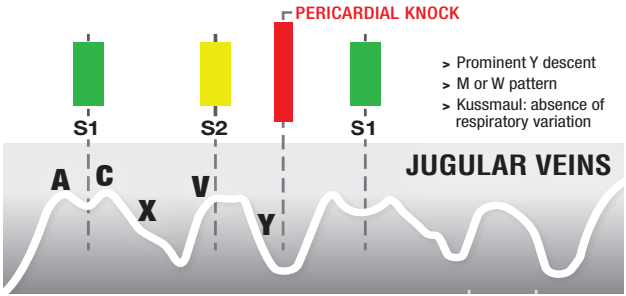
› Rapid early diastolic ventricular filling (prominent Y wave), which then ceases abruptly at mid-diastole (rigid pericardium)

PRESENTATION: systemic venous congestion mimicking right heart failure +

CLINICAL FEATURES: JVD; **prominent Y wave** (normal X descent; "M or W" pattern); **Kussmaul's sign** (increase or absence of decrease of CVP on inspiration); ± pulsus paradoxus (especially in the case of effusion - constriction); anasarca; hepatomegaly; pulsatile liver; signs of liver disease; jaundice; cardiac cachexia; low output state +

› **Pericardial knock:** high-pitched early diastolic sound at the apex or left parasternal region corresponding to the abrupt cessation of ventricular filling (± palpable) +

› **DDx of Kussmaul's sign: RV infarction; pulmonary embolism; RCM; TS; RA tumor; severe right heart failure** +



CXR: Pericardial calcifications

CT SCAN AND MRI: pericardial thickening **> 4 mm** (20% of patients have normal thickness); calcifications (CT scan); pericardial adhesions to the myocardium (MRI) +

TTE: abrupt cessation of ventricular filling at early diastole; abnormal respiratory movement of the septum (septal bounce); restrictive ventricular filling pattern; plethoric IVC

› **Exaggerated respiratory variations of transvalvular flow**
- Measure the first E wave following the start of inspiration and expiration
- **Mitral valve**: ↘ **E on inspiration; variation > 25% (Eexp - Einsp / Eexp)** +
- **Tricuspid valve**: ↘ **E on expiration; variation > 40% (Exp - Einsp / Eexp)**

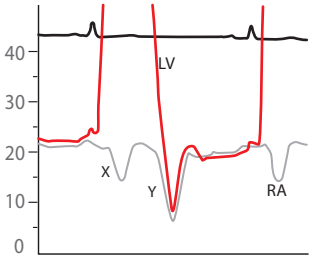
  - Variations masked if ↗ LA pressure (unmasked by asking the patient to sit up)
  - **DDx**: RV infarction; pulmonary embolism; pleural effusion; COPD (COPD: ↗ SVC anterograde systolic flow velocity > 20 cm/s on inspiration)

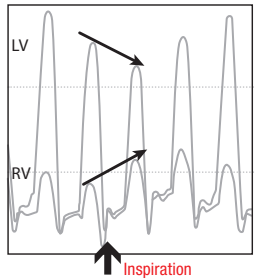
› **Pulmonary veins**: predominance of **diastolic flow** (↗ Y wave)

› **Hepatic veins: expiration →** decreased anterograde flow and increased diastolic reversal (A wave)

› **Tissue Doppler imaging of septal mitral annulus**: **E` > 8 cm/s** (*annulus paradoxus*) +

CARDIAC CATHETERIZATION





ATRIAL CURVE:
- Prominent Y descent
- W or M pattern
- Kussmaul

VENTRICULAR CURVE:
- Square root sign

VENTRICULAR CURVES:
- Equalization of end-diastolic pressures
- Respiratory discordance of ventricular systolic pressures

› **Ventricular curve: square root sign**: rapid initial ventricular filling, then increase and **equalization of end-diastolic pressures** of the chambers (≈ 20 mmHg)
- **LVEDP - RVEDP < 5 mmHg**
  - Can be detected with a bolus in the presence of dehydration

› **Interdependence: RV and LV systolic pressure discordance during respiration**

INSPIRATION

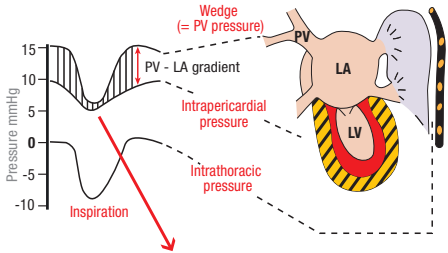
↓ Intrathoracic pressure
↓ Pulmonary venous pressure

(no change of intrapericardial pressure and LA pressure)

↓↓ **PV - LA PRESSURE GRADIENT**

=

↓ venous return to LV (septum shifted to the left)



Absence of transmission of respiratory intrathoracic pressure variations to the intrapericardial compartment (isolated by the thickened pericardium)

Adapted from*: Bunnell IL, Holand JF, Griffith GT, Greene DG. Hemodynamics during induced cardiac tamponade in man. Am J Med 1960;25:640-6*

MANAGEMENT

1. Diuretics (beware of decreased preload)
2. Avoid BB-CCB (compensatory tachycardia to maintain cardiac output)
3. **Pericardiectomy**: the only definitive treatment (perioperative mortality: 5-15%)
4. NSAID in acute effusive / constrictive pericarditis

5.6/ CONGENITAL ANOMALIES OF THE PERICARDIUM

PERICARDIAL CYST

Often adjacent to right chambers

Cardiac MRI PRN; Conservative management (except when compressive)

CONGENITAL ABSENCE OF THE PERICARDIUM

Most often partial absence of the left pericardium

COMPLICATIONS: hernia / strangulation of part of the heart; retrosternal chest pain - syncope - sudden death

ECG: Incomplete RBBB; poor precordial progression of R wave

CXR: Marked levoposition; loss of right heart contour; interposition of lung between Ao and main PA

TTE: Unusual imaging window (PLAX); RV appears dilated; exaggerated heart movements; abnormal movement of interventricular septum

CARDIAC MRI: Marked levoposition; presence of lung parenchyma between Ao and main PA and between inferior heart surface and diaphragm; ± hernia of part of the heart

TREATMENT: Pericardioplasty (in the presence of symptoms or hernia)

5.7/ CARDIOMYOPATHIES - CLASSIFICATION

Myocardial disease (abnormal structure and function) in the absence of CAD - HTN - valvular heart disease - congenital heart disease

▸▸| Classification (following page)

CARDIOMYOPATHIES

HCM

FAMILIAL

SARCOMERIC PROTEIN MUTATIONS

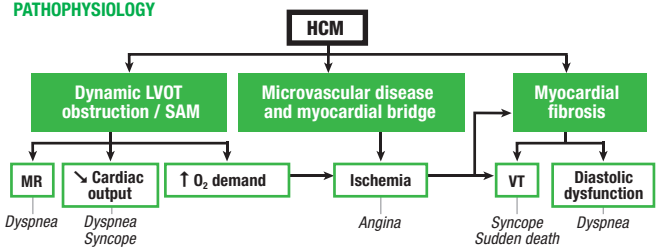
5.8/ HYPERTROPHIC CARDIOMYOPATHY

LV hypertrophy without dilatation and with no identifiable cause (see DDx)

Obstructive HCM (intraventricular gradient at rest or on exercise) versus non-obstructive HCM (gradient < 30 mmHg)

Autosomal dominant; sarcomere protein gene

PATHOPHYSIOLOGY



DIFFERENTIAL DIAGNOSIS

- Valvular heart disease; subaortic membrane; HTN (regression of LVH with tight blood pressure control); amyloidosis (TTR; AL); CRF; isolated basal septal hypertrophy in the elderly; acromegaly; phaeochromocytoma
- Syndromic: Noonan; LEOPARD; Friedreich's ataxia
- Glycogen storage disease; Lysosomal storage disease (Anderson-Fabry); Mitochondrial cytopathy
  - Symmetrical LVH; WPW (Danon and PRKAG2)
- High-level athlete

	ATHLETE	HCM
Genetic test or family history	Negative	Positive
Diastolic dysfunction	Absent	Present
LV end-diastolic diameter	> 55 mm	< 45 mm
SAM	Absent	Present
Asymmetrical LVH	Absent	Present
Severe LVH (> 17 mm)	Absent	Present
Regression of LVH after stopping training	Present	Absent
VO_2 max > 110% predicted	Present	Absent
Scar / fibrosis on MRI	Absent	Present

PRESENTATION: dyspnea; retrosternal chest pain; syncope; AF; malignant arrhythmia; sudden death

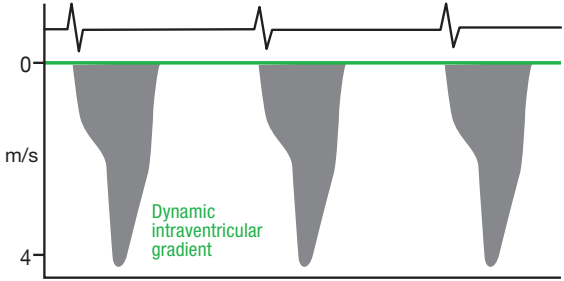
- Progression to DCM with systolic dysfunction ("burn-out" HCM): < 5%

CLINICAL FEATURES: rapid carotid upstroke with **pulsus bisferiens** ("*spike and dome*"); **3 components at apex** (early systolic wave; late systolic wave; S4); paradoxical split S2; **left parasternal systolic ejection murmur (↗ on Valsalva or on standing)**; MR murmur (radiation to axilla)

ECG: LVH; LAH; T - ST abnormalities (diffuse T wave inversion in apical HCM); Q waves; arrhythmias

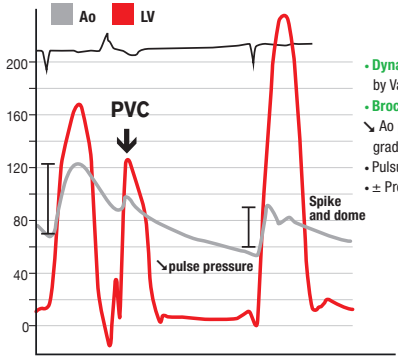
TTE (± CONTRAST): **A)** LV wall **≥ 15 mm** (that is not explained solely by loading conditions); asymmetrical septal hypertrophy (septum / posterior wall **> 1.5: 1**) and/or apical hypertrophy and/or anterolateral hypertrophy or concentric; ↗ LV mass; **B) SAM** (mid-to-late systolic MR with posterior jet); **C)** Dynamic intraventricular gradient **≥ 30 mmHg** amplified by Valsalva maneuver (continuous Doppler shows **a late-peaking dagger-shaped appearance**); **D)** Diastolic dysfunction; **E)** Structural abnormality of the mitral valve (elongated leaflets; abnormal insertion of anterolateral papillary muscle); **F)** LA dilatation; **G)** Apical aneurysm

› **Exercise echocardiography**: in symptomatic patients to detect a significant dynamic intraventricular gradient (≥ 50 mmHg) when absent at rest



› **DDx of Dynamic intraventricular gradient**: Takotsubo; cardiac amyloidosis; anterior myocardial infarction (basal hyperdynamism); post-AVR (AS with LVH); sigmoid septum in eldery people; hypertensive heart disease; small hyperdynamic LV

CARDIAC CATHETERIZATION



- **Dynamic intraventricular obstruction** (revealed by Valsalva or Isuprel or PVC or Nitrates)
- **Brockenbrough-Braunwald-Morrow sign**: ↘ Ao pulse pressure post-PVC (and ↗ LV-Ao gradient)
- Pulsus bisferiens (spike and dome appearance)
- ± Prominent v wave (MR due to SAM)

STRESS TEST: evaluate functional capacity; look for abnormal BP response (**↘ BP > 20 mmHg or absence of increase of BP > 20 mmHg**); combine with echocardiography to demonstrate dynamic obstruction; repeat stress test every 2-3 years in clinically stable patients

CARDIAC MRI: LVH; Rule out apical HCM; late gadolinium enhancement (interventricular septum; free wall; RV insertion sites) with **≥ 10% of LV mass associated with increase SCD risk**

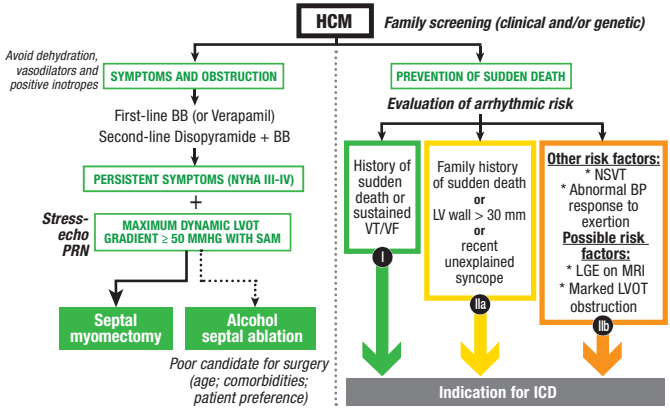
BIOPSY: disorganized myocyte architecture; interstitial fibrosis

GENETIC TEST: indicated routinely (Class I); enables cascade genetic screening of the relatives; positive in 60-70% of cases

MANAGEMENT

- Avoid strenuous exertion / competitive sports
- **Hypotension due to LVOT obstruction**: **volume; BB; Phenylephrine**
- **Anticoagulation** for AF irrespective of CHADSVASc score
- **Family screening:** 1st degree relatives; clinical and/or genetic screening

12 - 18 YEARS OR COMPETITIVE SPORTSMAN	> 18 YEARS
ANNUAL ECG / TTE	ECG / TTE EVERY 5 YEARS



- **Septal myomectomy**: preferable in most cases (especially young patients; septum > 30 mm; other concomitant surgical indication; structural abnormality of mitral valve)
  - **Complications:** mortality (1%); complete AV block (2%); LBBB; iatrogenic VSD (< 1%); Ao valve lesion (AR)
- **Alcohol septal ablation:** selective injection of alcohol into perforating septal coronary branches; under ultrasound guidance (with intracoronary contrast); "controlled" infarction targeting the basal ventricular septum at the site of SAM
  - **Complications:** mortality (2%); complete AV block (10-20%); RBBB; in-hospital VT (5%); repeat procedures (12%); possible long-term arrhythmic risk

PROGNOSIS: cardiovascular death 1-2 % / year; the majority of patients have a **similar life expectancy to that of the general population**; identify patients with increased risk of sudden death

HCM RISK-SCD (5 years): $= 1 - 0.998^{\text{Prognostic index}}$; **consider ICD if 5-year risk ≥ 6%**

- **Prognostic index:** = [0.15939858 x maximal wall thickness (mm)] – [0.00294271 x maximal wall thickness^2 (mm^2)] + [0.0259082 x LA diameter (mm)] + [0.00446131 x maximal LVOT gradient (mmHg)] + [0.4583082 x familial history SCD] + [0.82639195 x NSVT] + [0.71650361 x unexplained syncope] – [0.01799934 x age (years)]

5.9/ DILATED CARDIOMYOPATHY

Ventricular dilatation and systolic dysfunction

Idiopathic in 50% of cases

CLINICAL FEATURES: JVD; lateralized and enlarged apex; S3; S4; AV valve regurgitation

COMPLICATIONS: Heart failure; arrhythmias; conduction disorders; thromboembolism; sudden death

ECG: Sinus tachycardia; arrhythmias; T - ST abnormalities; LVH; poor precordial progression of R wave; conduction disorders

TTE: Spherical LV; thinned walls; dilated chambers; MR (Carpentier I and IIIb); limited aortic valve opening; LVOT VTI < 18 cm; ↘ dP/dT; thrombus; diastolic dysfunction; pericardial effusion; PHT

ASSESSMENT: CXR; CBC; Electrolytes; Phosphorus; Calcium; Renal function; LFTs; TSH; CK; ANA; ESR; CRP; Iron assessment; HIV; Urinalysis; Blood glucose; Lipid profile; ± Lyme antibody titer; ± Urine metanephrines; ± BNP

› **Family screening / Genetic Test**: consider when: **A)** DCM is possibly familial; **B)** DCM with AV block and/or sudden death in the family (LMNA; SCN5A)

SPECIFIC ENTITIES

TACHYCARDIOMYOPATHY: secondary to sustained supraventricular or ventricular tachycardia; recovery of LV function by aggressive rhythm control or rate control within 4 weeks

› **AF**: BB; Amiodarone x 1 month then cardioversion; Digoxin; RF ablation

ALCOHOLIC CARDIOMYOPATHY: improvement of LVEF with abstinence

› **Harmful effects of alcohol (heavy drinking)**: systolic and/or diastolic dysfunction; HTN; CAD **(decreased risk with low consumption / 1 to 2 standard drinks per day)**; stroke; arrhythmia - AF; sudden death; hypertriglyceridemia

OBESITY-RELATED CARDIOMYOPATHY: Secondary to ↗ cardiac output and myocardial fat infiltration; LV dilatation then LV dysfunction

› Suspect when BMI > 40 kg/m^2 (for more than 10 years); Diagnosis of exclusion

CHAGAS DISEASE (TRYPANOSOMIASIS): *Trypanosoma cruzi*; transmission of the parasite by *Triatominae* bugs

› **Early infection**: Acute myocarditis; ± meningoencephalitis / skeletal muscle involvement / nerve involvement
  - **Treatment**: Nifurtimox or Benznidazole
  - **Reactivation**: Immunosuppression / HIV / heart transplant
› **Latent infection**: Mild lymphocytic myocarditis
› **Chagas cardiomyopathy:** 30% of patients; several years after infection; autoimmune myocarditis (little or no residual parasites); dilatation of chambers; ventricular dysfunction (RV then LV); apical and inferolateral aneurysm; thrombus (apex; RAA); embolism; ventricular arrhythmia; blocks; cardiac dysautonomia

5.10/ RESTRICTIVE CARDIOMYOPATHY

High filling pressure secondary to **rigid myocardium** due to **myocardial or endomyocardial fibrosis or following infiltration of the myocardium by a substance**

PRESENTATION: dyspnea; weakness; edema / anasarca; AF

CLINICAL FEATURES: JVD; Kussmaul's sign; S3; S4; palpable apex (contrary to constriction); AV valve regurgitation; hepatomegaly; ascites; peripheral edema

ECG: low voltage; conduction disorders; poor precordial progression of R wave; AF

TTE: bi-atrial dilatation; normal or decreased ventricular volume; normal or slightly increased wall thickness; sparkling myocardium; thickening of valves / interatrial septum; diastolic dysfunction with restrictive pattern; effusion

	CONSTRICTION	RESTRICTION
Y descent	Prominent	Prominent
Pulsus paradoxus	Sometimes present (1/3)	Absent
Palpable apex	No	Yes
Pericardial knock	Present	Absent
LV filling pressure > 25 mmHg	Rare	Frequent
Square root sign	Present	Present
LVEDP - RVEDP (equalization of diastolic pressures)	< 5 mmHg	> 5 mmHg
RVEDP / RVSP (pulse pressure)	> 0.33	< 0.33
sPAP	< 50 mmHg	> 50 mmHg
Ventricular interdependence (discordant respiratory variations of RV and LV pressures)	Present (pressure discordance)	Absent (pressure concordance)
Diastolic pattern	Restrictive	Restrictive
Respiratory variations of transvalvular flow	Exaggerated • **M valve**: > 25 % variation • **T valve**: > 40 % variation	Normal • **M valve**: about 5% variation
Mitral septal annulus E`	> 8 cm/s	< 8 cm/s
Hepatic veins: ↗ diastolic reversal	Expiratory	Inspiratoire
Ventricular wall thickness	Normal	± Increased
Pericardial thickness	± Increased	Normal
Atrial dimensions	± LA dilatation	Bi-atrial dilatation ++
Abnormal respiratory movement of the septum	Present	Absent
BNP	Often normal	Increased

BIOPSY: Rule out infiltration (amyloidosis; sarcoidosis; Gaucher; Hurler's)

MANAGEMENT

- Treatment of underlying cause
- Control of blood volume is difficult (hypotension if ↘ preload)
- Caution with BB and CCB: cardiac output depends on HR (**fixed stroke volume** due to poor filling)

SPECIFIC ENTITIES

SCLERODERMA: microvascular spasm with ischemia and necrosis / fibrosis

HEMOCHROMATOSIS: tissue iron deposits (heart; liver; gonads; pancreas; skin)

- Autosomal recessive; HFE gene mutation
  - **Secondary iron overload:** repeated transfusions; ineffective erythropoiesis
- **Pentad:** heart failure; cirrhosis; impotence; DM; arthritis
- **Cardiac involvement**: **diastolic dysfunction - RCM (possibly followed by systolic dysfunction); LV dilatation - DCM;** conduction disorders
- **Assessment**: ↗ **ferritin (> 200 µg/L in premenopausal women; > 300 µg/L in men or postmenopausal women);** ↗ **transferrin saturation (> 50% in women and > 60% in men)**
- **MRI**: ↘ **relaxation time on T2* (< 20 ms)**
- **TREATMENT**: **Phlebotomies; Chelator (Deferoxamine)**

FABRY DISEASE: X-linked; α-galactosidase A deficiency; accumulation of glycosphingolipids in lysosomes

- **Diagnosis**: ↗ urinary globotriaosylceramide; skin biopsy
- Variable degree of enzyme deficiency: **A) Total deficiency**: neuropathies; renal / skin / cardiac involvement; stroke; **B) Partial deficiency**: isolated cardiac involvement is possible
- **Cardiac involvement**: LVH mimicking HCM; Diastolic dysfunction - RCM; angina / myocardial infarction (endothelial infiltration); HTN; MVP
- **Management**: enzyme replacement therapy

SARCOIDOSIS: multisystem noncaseating granulomas (particularly in lungs / reticulo-endothelial system / skin)

- **Cardiac involvement**: infiltration of cardiac conduction tissue and myocardium (IV septum; LV free wall); blocks; ventricular arrhythmias; RCM; systolic LV dysfunction; LV dilatation; LV aneurysm; RWMA not corresponding to coronary anatomy; pericarditis; valvular heart disease; cor pulmonale (pulmonary fibrosis)
- **Biopsy**: often falsely negative
- **MRI**: late gadolinium enhancement reflecting intramural or subepicardial fibrosis (often anteroseptal or inferolateral)
- **PET-FDG:** demonstrates patchy zones of fibrosis and/or inflammation
- **Management**: Corticosteroids; Plaquenil; Methotrexate; Cyclophosphamide; ICD; Transplant (risk of recurrence)

ENDOMYOCARDIAL FIBROSIS (DAVIES DISEASE): Tropical regions; ± eosinophilia; fibrosis / thrombus / endocardial obliteration (obliteration of apex; papillary muscle fibrosis; AV valve regurgitation); bi-atrial dilatation; diastolic dysfunction with restrictive pattern

LOEFFLER ENDOCARDITIS (HYPEREOSINOPHILIC SYNDROME): Eosinophilia > 1 500 cells/µL with multisystem involvement (lung; CNS; GI; skin)

- **Cardiac involvement**: **myocarditis followed by replacement of the myocardium by thrombus then formation of endomyocardial fibrosis;** fibrosis / thrombus / endocardial obliteration (apex; posterior mitral leaflet; posterobasal wall); RCM; AV valve regurgitation; embolism
- **Management:** anticoagulation; Corticosteroids; Hydroxyurea; Interferon; endocardiectomy; valve replacement / repair

CARCINOID SYNDROME: Gastrointestinal tract (small bowel) or bronchial tumor; release of serotonin by the tumor and liver metastases; ↗ urinary 5-HIAA

- **Symptoms**: skin flushing; diarrhea; bronchospasm; hypotension
- **Cardiac involvement**: **Fibrous endomyocardial plaques in right heart chambers**; tricuspid and pulmonary valve disease with thickening / retraction / rigidity of leaflets (TR and PR due to malcoaptation; ± TS; ± PS); right ventricular dilatation and dysfunction
  - **Involvement of left chambers in the presence of R→L shunt or lung metastases**
- **Management:** Somatostatin analogs; embolization of liver metastases; TVR if severe symptoms and/or dilatation – progressive RV dysfunction (despite adequate control of the cancer)

5.11/ CARDIAC AMYLOIDOSIS

Interstitial infiltration of a protein demonstrating apple-green birefringence when stained with Congo Red

PRIMARY AMYLOIDOSIS (AMYLOIDOSIS AL)

Plasma cell dyscrasia (plasma cell clone); tissue deposits of a portion of **immunoglobulin light chains**

CARDIAC INVOLVEMENT (50% OF PATIENTS): median survival = 15 months; LVH; RCM; progressive LV dysfunction; ischemia (microvascular infiltration); conduction disorders; atrial disease; sudden death (pulseless electrical activity)

SYSTEMIC INVOLVEMENT: OH; peripheral / autonomic neuropathy; carpal tunnel; periorbital purpura; ecchymoses; macroglossia; RUQ pain; onychodystrophy; renal failure / nephrotic syndrome

CLINICAL FEATURES: hypotension / OH; JVD; Prominent X and Y waves; Kussmaul; S4 rarely present (atrial disease); pleural effusions; hepatomegaly; anasarca

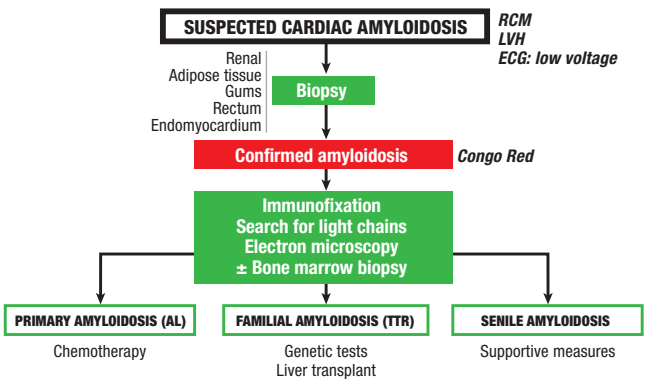
ECG: microvoltage (despite LVH on TTE) ; AF; pseudo-infarction; blocks

TTE: thickened walls; small ventricular chamber; dynamic LVOT obstruction; valvular / interatrial septum infiltration; sparkling myocardium; diastolic dysfunction; possible systolic dysfunction; pericardial effusion; bi-atrial dilatation

CARDIAC MRI: rapid accumulation of contrast in myocardium (**rapid wash-out from blood**); circumferential subendocardial or patchy transmural late gadolinium enhancement; atrial left gadolinium enhancement

DIAGNOSIS: biopsy of abdominal adipose tissue (positive in > 70% of cases) or gums or salivary glands or kidney or rectum or endomyocardial tissue

- If Congo Red positive → **Distinguish primary (AL) from familial (TTR) amyloidosis**
  - Serum and urinary immunofixation (± SPEP and UPEP)
  - Electron microscopy immunohistochemistry techniques
  - Abnormal kappa / lambda light chain ratio
- Bone marrow biopsy: % plasma cells; rule out MM and Waldenström



MANAGEMENT

- Cautious use of Lasix; **particular caution with vasodilators and Digoxin**
- Anticoagulation in the presence of AF or atrial disease (A wave < 20 cm/s)
- **Anti-plasma cell chemotherapy**: Melphalan / Dexamethasone or Cyclophosphamide / Thalidomide / Dexamethasone; High-dose chemotherapy combined with autologous bone marrow transplantation as required

FAMILIAL AMYLOIDOSIS

Mutant transthyretin protein (TTR) (in the majority of cases)

Autosomal dominant; most patients develop clinical features after the age of 40 years

PRESENTATION: various degrees of cardiac / conduction tissue / peripheral nerve / renal involvement

TREATMENT: **liver transplant** (mutant TTR produced by the liver)

SENILE CARDIAC AMYLOIDOSIS

Non-mutant transthyretin protein (TTR)

Rare extracardiac involvement

SUSPECT: in an elderly patient with heart failure + LV wall thickening + normal chamber dimensions; frequent blocks; AF

DIAGNOSIS: endomyocardial biopsy

Median survival: 7.5 years

5.12/ ARRHYTHMOGENIC RIGHT VENTRICULAR DYSPLASIA (ARVD)

RV dysfunction (regional or global) secondary to infiltration of the myocardium by fibrous / adipose tissue

- **Triangle of dysplasia**: lesion of the RV inflow tract, RV outflow tract and apex of the RV
- LV is sometimes involved; can mimic DCM

AUTOSOMAL DOMINANT: majority of cases; desmosome protein gene

- **Autosomal recessive**: **Naxos syndrome** (plakoglobin; woolly hair; palmoplantar keratoderma); **Carvajal syndrome** (desmoplakin; palmoplantar keratoderma; predominant LV involvement)

4 PHASES

1. Asymptomatic
2. Arrhythmic (palpitations; syncope; VT – sudden death)
3. Right heart failure
4. Biventricular failure / DCM

DIAGNOSIS: requires the presence of several criteria

MAJOR CRITERIA	MINOR CRITERIA
01. Structural lesion	
TTE a) RV: **regional akinesia or dyskinesia or aneurysm +** b) **PLAX RVOT ≥ 32 mm or PSAX RVOT ≥ 36 mm** (end-diastole) or FAC ≤ 33% **MRI** a) RV: regional akinesia or dyskinesia or dyssynchrony + b) RV end-diastolic volume ≥ 110 mL/m² (M) or ≥ 100 mL/m² (F) or RVEF ≤ 40% **Angiography** • RV: regional akinesia or dyskinesia or aneurysm	**TTE** a) RV: regional akinesia or dyskinesia + b) PLAX RVOT 29 to 32 mm or PSAX RVOT 32 to 36 mm (end-diastole) or FAC 33% to 40% **MRI** a) RV: regional akinesia or dyskinesia or dyssynchrony + b) RV end-diastolic volume 100 to 110 mL/m² (M) or 90 to 100 mL/m2 (F) or RVEF 40 to 45%
02. Tissue characterization (biopsy)	
Residual myocytes < 60% with fibrous replacement of RV free wall with or without fat replacement	Residual myocytes 60 - 75% with fibrous replacement of the RV free wall with or without fat replacement
03. Repolarization abnormalities	
T wave inversion in V1-V2-V3 (absence of cRBBB with QRS ≥ 120 ms)	• T wave inversion in V1-V2 (absence of RBBB with QRS ≥ 120 ms) or V4 or V5 or V6 • T wave inversion in V1-V2-V3-V4 with cRBBB
04. Depolarization / conduction abnormalities	
Epsilon wave in V1-V2-V3 (low amplitude signal between the end of the QRS and the start of the T wave) 	• Late potentials (SAECG): ≥ 1/3 positive parameters (absence of QRS ≥ 110 ms on basic ECG) a) Filtered QRS ≥ 114 ms b) Terminal QRS (< 40 µV) ≥ 38 ms c) RMS (Root mean square) of terminal 40 ms ≤ 20 µV • QRS: S nadir to the end of the QRS ≥ 55 ms in V1- V2-V3 (absence of cRBBB)
05. Arrhythmias	
NSVT or VT with LBBB morphology with superior axis (negative QRS in II - III - aVF and positive QRS in aVL)	• NSVT or VT of RVOT, LBBB morphology with inferior axis (positive QRS in II - III - aVF and negative QRS in aVL) or unknown axis • > 500 PVCs per 24 h
06. Family history	
• **1st degree relative meeting the criteria** • **1st degree relative with histologically confirmed diagnosis** • **Pathogenic mutation**	• History of ARVD in 1st degree relative (but impossible to verify criteria) • Sudden death < 35 years in a 1st degree relative with suspected ARVD • Confirmed ARVD (histology or criteria) in a 2nd degree relative
• **Definitive diagnosis:** 2 major or 1 major + 2 minor or 4 minor (different categories) • **Borderline diagnosis:** 1 major + 1 minor or 3 minor (different categories) • **Possible diagnosis:** 1 major or 2 minor (different categories)	

Marcus FI, McKenna WJ, Sherrill D, et al. Diagnosis of Arrhythmogenic Right Ventricular Cardiomyopathy/Dysplasia. Proposed Modification of the Task Force Criteria. Circulation. 2010;121; 1533-1541.

OTHER ELEMENTS TO LOOK FOR: A) ↗ QRS duration > 100 ms in V1 (delayed activation of RV; RBBB); **B)** Multiple RV scars on electrophysiological voltage mapping; **C)** Fat infiltration of RV on MRI (marked inter-observer variability)

DDX: A) DCM; **B)** Uhl's anomaly (zones in RV with absence of myocardium; endocardium and epicardium are continuous); **C)** Idiopathic RVOT VT (ECG / SAECG / TTE all normal); **D)** Myocarditis; **E)** Sarcoidosis

MANAGEMENT

- Avoid competitive sports or symptomatic exertion; Screening in 1st degree relatives
- Treatment of heart failure: ACE inhibitors; BB; Heart transplantation PRN
- ICD:
  a) **Secondary prevention**: documented sustained VF / VT
  b) **Primary prevention**: consider ICD → unexplained syncope; frequent NSVT; family history of premature sudden death; extensive disease (extensive RV involvement; LV involvement); marked QRS prolongation; VT induction during EPS
  c) **Frequent shocks**: Sotalol; Amiodarone; VT ablation

5.13/ ISOLATED LEFT VENTRICULAR NONCOMPACTION

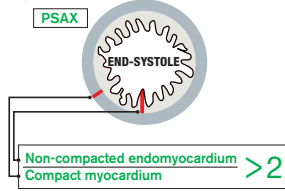
Failure of endomyocardial compaction during embryogenesis

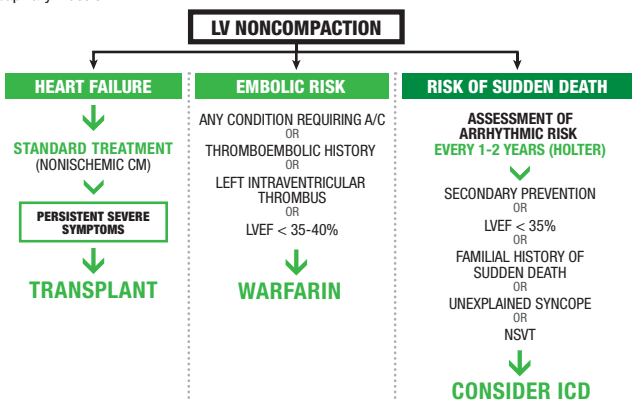
Prominent trabeculations with deep intertrabecular crypts

Isolated (autosomal dominant or sporadic) vs **associated with congenital heart disease** (Ebstein; RVOT or LVOT obstruction; complex heart disease)

PRESENTATION: heart failure; arrhythmia; sudden death; embolism

TTE (± CONTRAST): thin epicardial layer with thick non-compacted endomyocardial layer (predominantly apical and middle portions of inferior and lateral walls); **intertrabecular crypts continuous with the intraventricular cavity** (blood flow on color Doppler); RWMA; LV dysfunction; thrombus; abnormal papillary muscle





MRI: non-compacted endomyocardium / compacted myocardium ratio > **2.3 in diastole**

MANAGEMENT: screening of 1st degree relatives (TTE); avoid competitive sports

5.14/ TAKOTSUBO CARDIOMYOPATHY (STRESS CARDIOMYOPATHY)

Transient systolic dysfunction involving the apex (± midventricular walls) in the absence of any significant CAD; often following an intense emotional or physical stress

- Secondary to catecholamine surge
- Postmenopausal women in > 90% of cases
- **Variants**: isolated midventricular lesion or reverse Takotsubo (basal akinesia)

PRESENTATION: Retrosternal chest pain; ST elevation on ECG or diffuse T wave inversion (with ↗ QT); ↗ troponin (limited); negative coronary angiography

- **Complications**: hemodynamic instability (LVOT obstruction ± SAM secondary to basal hyperdynamism in 15% of cases); heart failure; arrhythmias; thromboembolism; MR (SAM)
- **Complete recovery of LV function in 1 to 3 months; good prognosis**

CARDIAC MRI: myocardial edema; apical akinesia; absence of fibrosis - necrosis

DDX: Intracranial hemorrhage or SAH (often **basal and mid-ventricular akinesia**); major stroke; Pheochromocytoma (rule out if recurrence); Vasospasm; Cocaine; Amphetamines; Myocarditis

MANAGEMENT

- Carvedilol (alpha / beta blocker)
- ACE inhibitor (stop after recovery)
- TTE at 1 and 3 months (consider alternative diagnosis if LV dysfunction persists)
- **Anticoagulation: A)** Anticoagulant therapy if LV thrombi; **B)** Prophylactic anticoagulation may be considered to prevent LV thrombi (class IIb recommandation)
- **Hypotension / Shock**:
  - **Severe systolic dysfunction without LVOT obstruction**: Amines (cautiously); IABP as required
  - **LVOT obstruction:** BB (avoid amines); Volume (in absence of overload); Phenylephrine (cautiously)

5.15/ MYOCARDITIS

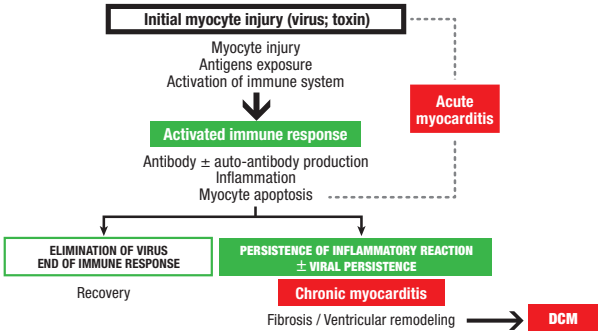
Inflammation of the myocardium

DALLAS CRITERIA: presence of **inflammatory cells** (lymphocytes) ± **myocyte necrosis** on biopsy; poor sensitivity (often falsely negative)

ETIOLOGIES

- **Virus:** Coxsackievirus; echovirus; adenovirus; parvovirus B19; CMV; HSV6; HIV; influenza; HCV; EBV
- **Bacteria / Spirochete:** TB; *Chlamydia pneumoniae; Streptococcus; Mycoplasma pneumoniae; Treponema pallidum; Clostridium*; Diphtheria; Whipple; Lyme
- **Fungi:** *Aspergillus; Candida; Coccidioides; Cryptococcus; Histoplasma*
- **Parasites:** Chagas; Schistosomiasis; Echinococcosis
- **Toxins:** Anthracyclines; Cocaine; 5-FU; phenytoin; cyclophosphamide; arsenic; iron; radiotherapy; alcohol; amphetamines; carbon monoxide; heatstroke; hypothermia; insect / snake bite
- **Hypersensitivity:** clozapine; sulfonamides; cephalosporins; tetracyclines; PNC; tricyclic antidepressants; allopurinol; dobutamine; diuretics
- **Autoimmune:** giant cell myocarditis; Churg-Strauss; Sjögren; inflammatory bowel disease; celiac disease; sarcoidosis; SLE; Takayasu arteritis; Wegener; dermatomyositis; Kawasaki; RA; scleroderma; thyrotoxicosis

PATHOPHYSIOLOGY



PRESENTATION

Compatible symptoms: Acute retrosternal chest pain mimicking myocardial infarction or pericarditis; heart failure; palpitations; syncope; sudden death; cardiogenic shock; viral prodromes; fever

+ ≥ 1 DIAGNOSTIC CRITERION

ECG: AV block (Lyme; giant cell; sarcoidosis); branch block; ST-T abnormalities; PVCs; VT - VF; AF; sinus arrest; low voltage; Q waves	**Myocardiocytolysis:** elevated troponins	**Structural / functional abnormalities (TTE)**: RWMA; systolic dysfunction; ventricular dilatation; wall thickening; effusion; thrombus	**MRI (Lake Louise criteria)** • **Early gadolinium enhancement on T1** indicating inflammation (myocardium vs skeletal muscle enhancement ratio > 4.0) • **Late gadolinium enhancement** indicating fibrosis (intramural or subepicardial; often anteroseptal or inferolateral) • **↗ T2 signal intensity** indicating edema (myocardium vs skeletal muscle signal ratio > 2.0)

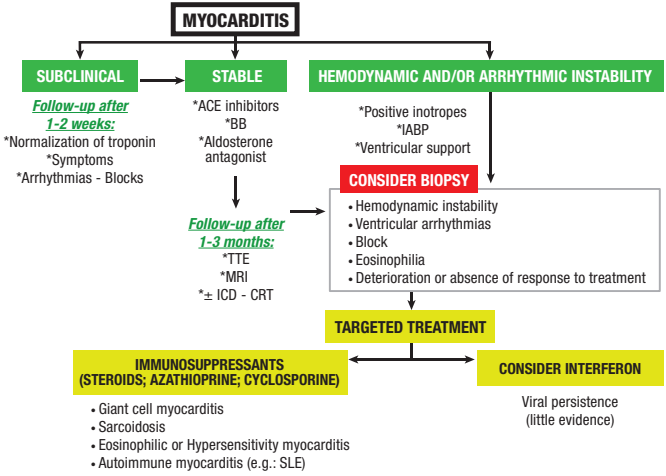
- **Fulminant lymphocytic myocarditis**: < 2 weeks after a viral infection; hemodynamic instability; diffuse LV dysfunction (rarely dilatation); wall thickening (edema); good prognosis with support
- **Giant cell myocarditis**: heart failure (evolving over several weeks to several months); blocks; ventricular arrhythmias; deterioration despite treatment; often underlying autoimmune disease (thymoma; Crohn); median survival < 6 months; Treatment: immunosuppression; transplant
- **Acute lymphocytic myocarditis**: may mimick acute MI (with negative coronary angiography) or may present with progressive LV dysfunction / dilatation or fulminant myocarditis; can progress to DCM
- **Eosinophilic myocarditis**: Hypersensitivity or Loeffler endocarditis or acute necrotizing eosinophilic myocarditis
  - **Hypersensitivity**: drug reaction; rash; fever; multiple organ dysfunction; eosinophilia; Myocarditis; Treatment with corticosteroids
  - **Acute necrotizing eosinophilic myocarditis**: rare; poor prognosis
- **Chronic active myocarditis**: insidious; LV systolic dysfunction (sometimes diastolic with restrictive pattern); ± viral persistence

DEFINITIVE DIAGNOSIS: myocarditis with **histological and/or immunohistological proof** on biopsy

CONSEQUENCES: viral persistence and/or persistent activation of immune system; chronic myocarditis; myocyte necrosis / fibrosis; remodeling; DCM; arrhythmia - sudden death

MANAGEMENT

› Avoid strenuous exertion / competitive sports for ≥ 6 months



5.16/ INDICATIONS FOR ENDOMYOCARDIAL BIOPSY

1.	Heart failure for < **2 weeks** with hemodynamic compromise **(fulminant lymphocytic myocarditis; necrotizing eosinophilic myocarditis; giant cell myocarditis)** (I;B)
2.	Heart failure for **2 weeks to 3 months** with LV dilatation and ventricular arrhythmias or AV block (2nd or 3rd degree) or absence of response to treatment (1-2 weeks) **(giant cell myocarditis or eosinophilic myocarditis)** (I;B)
3.	Heart failure for > 3 months with LV dilatation and ventricular arrhythmias or AV block (2nd or 3rd degree) or absence of response to treatment (1-2 weeks) **(sarcoidosis or Chagas)** (IIa;C)
4.	Heart failure with dilated cardiomyopathy and suspicion of allergic reaction and/or eosinophilia (eosinophilic myocarditis) (IIa; C)
5.	Heart failure with suspicion of anthracycline cardiomyopathy (detect at an early stage of cardiotoxicity) (IIa; C)
6.	Heart failure with unexplained RCM (IIa; C)
7.	Suspected cardiac tumor (with the exception of myxoma), when noninvasive method is inconclusive (IIa; C)

COMPLICATIONS OF BIOPSY: 3%; venous access (arterial puncture; pneumothorax; bleeding); arrhythmia; blocks - RBBB; valve injury; cardiac perforation; tamponade; death; stroke (LV biopsy)

5.17/ CARDIAC TUMORS

METASTASIS

Direct extension; hematogenous; extension via IVC (Hypernephroma; intravenous leiomyomatosis)

Lung; Breast; Lymphoma; Leukemia; Kaposi; Esophagus; Melanoma; Stomach; Mesothelioma; Thyroid; Renal; Extracardiac sarcoma

PRIMARY TUMORS

75 % benign +

SYSTEMIC FEATURES: fever; malaise; weight loss; anemia

EMBOLIC PHENOMENA: tumor embolism or thromboembolism

CARDIAC SIGNS: **depending on the site of the tumor**; blocks - arrhythmia; valve obstruction or regurgitation; SVC syndrome; coronary artery compression; hemorrhagic pericardial effusion (angiosarcoma; lymphoma); heart failure

DIAGNOSIS: TTE; TEE; CT scan or MRI **(mass visible if > 1 cm)**; biopsy; metastatic work-up of malignant tumors; PET scan

- **MRI:** distinction between tumor and thrombus (according to gadolinium enhancement); tissue characterization

MYXOMA

Pedunculated mass with stalk attached to the endocardium (often interatrial septum)

LA (80%); RA (10%); > 90% are solitary

PRESENTATION: Constitutional symptoms; embolisms (tumor fragment or thrombus); valve obstruction (can vary according to the position; look for tumor "plop"); extracardiac metastases

Recurrence in 3% of cases; TTE follow-up for life

Family screening (5 to 10% are familial)

- **Carney complex**: autosomal dominant; multiple intracardiac and extracardiac myxomas; high recurrence rate; cutaneous lentigines; other tumors (testicular; pituitary; thyroid)

TREATMENT: surgical resection

PAPILLARY FIBROELASTOMA

On **valvular endocardium** (80-90%); aortic valve (40%; aortic side); mitral valve (30%; ventricular side); rarely endocardium of LA or LV; solitary (90%)

Friable lesion measuring about 1 cm; resembles a sea anemone; adherent thrombus; 45% have a stalk (1-3 mm)

COMPLICATIONS: thromboembolism

TREATMENT: surgical resection (especially if embolism or mobile or > 1 cm)

LIPOMA

Especially subendocardial (also subepicardial or myocardial)

Predominantly solitary (multiple in the case of tuberous sclerosis)

MRI: fatty mass

COMPLICATIONS: obstruction; pericardial effusion; block; arrhythmias

TREATMENT: surgical resection when symptomatic

LIPOMATOUS HYPERTROPHY OF INTERATRIAL SEPTUM

Excessive fat accumulation in the interatrial septum

Thickening spares the fossa ovale; dumbbell appearance

Associated with obesity and age > 70 years

COMPLICATIONS: Blocks; arrhythmias; SVC obstruction (rare)

RHABDOMYOMA

Children; **associated with tuberous sclerosis** (autosomal dominant; epilepsy; skin lesions; hamartomas)

Ventricles > atria; **multiple lesions; spontaneous regression**

FIBROMA

Children (sometimes adults)

Solitary intramural mass; interventricular septum or LV free wall

TREATMENT: Surgical resection when symptomatic (arrhythmia; blocks; obstruction)

HEMANGIOMA / LYMPHANGIOMA

Intrachamber (ventricle > atrium) / intramural / epicardium / pericardium

Coronary angiography sometimes demonstrates the tumor blood supply

PRESENTATION: asymptomatic; palpitations; heart failure; pericardial effusion; obstruction; embolism; AV block

TREATMENT: echocardiographic follow-up (may increase in size or disappear); surgical resection when symptomatic

MALIGNANT TUMORS

ANGIOSARCOMA

- **RA in 90% of cases** (intramural mass protruding into the chamber)
- Frequent pericardial involvement
- Metastasis at presentation in 70-80% of cases (lung; liver; CNS; bone)
- Mean survival: 10 months
- **Treatment:** Surgery; Radiotherapy; Chemotherapy (Doxorubicin); Neoadjuvant chemotherapy (reduce tumor size prior to surgery); IL-12; autologous transplant (with ex vivo resection); transplant; palliative care

RHABDOMYOSARCOMA

- Children - young adults
- Multiple lesions (60%); no predilection for a particular chamber
- Aggressive, invasive tumor; metastases (lungs; lymph nodes)
- Survival < 1 year

LEIOMYOSARCOMA

- **LA (70-80 %)**; solitary (70%)
- Rapid growth; metastases; mean survival: 6 months

CARDIAC LYMPHOMA

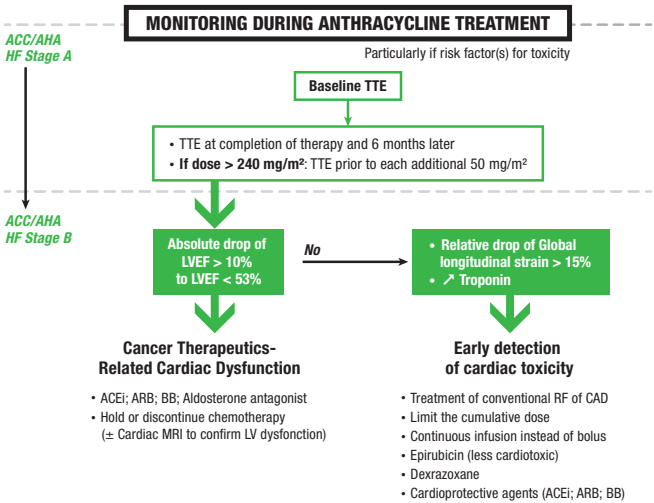
- Right heart (70%); solitary (66%)
- Pericardial effusion (50%)
- Frequent extracardiac disease at the time of presentation
- **Treatment:** Anthracycline; Radiotherapy; Rituximab

5.18/ CARDIAC COMPLICATIONS OF CANCER

COMPLICATIONS: A) Metastases; **B)** Pericardial effusion; **C)** Tamponade; **D)** Constriction (radiotherapy); **E)** SVC obstruction; **F)** Valvular heart disease (metastases; infective endocarditis or non-bacterial thrombotic endocarditis; radiotherapy; obstruction; carcinoid); **G)** CAD (common risk factors; cancer chemotherapy; radiotherapy); **H)** Hyperviscosity (erythrocytosis or thrombocytosis or leukocytosis; ↗ Ig); **I)** Cardiotoxicity of chemotherapy and radiotherapy

ANTHRACYCLINE TOXICITY: (Doxorubicin; Daunorubicin; Epirubicin; Idarubicin)

- **Acute toxicity:** myocarditis; pericarditis; pericardial effusion; arrhythmia; ventricular dysfunction
- **Chronic toxicity: type I cardiotoxicity (irreversible, dose-dependant damage) leading to ↘ LVEF / DCM**
- **Risk factors for toxicity: cumulative dose > 350 mg/m²**; bolus; females; young; > 65 ans; + risk factors for heart disease; history of heart disease; mediastinal radiotherapy; **Trastuzumab (TTE every 3 months during treatment) or Cyclophosphamide or Paclitaxel**; baseline LVEF < 55 %



MEDIASTINAL RADIOTHERAPY: **fibrosis and calcification of cardiac structures;** complications often occur 10-20 years post-exposure; **higher risk with cumulative dose > 30 Gy**

- **Complications**: **A)** Accelerated CAD; **B)** Blocks / Conduction system disease; **C)** Valvular heart disease (thickening / fibrosis / calcification; predominant on left-sided valves; regurgitation > stenosis); **D)** Constrictive pericarditis; Pericardial effusion; **E)** Diffuse myocardial fibrosis with diastolic dysfunction / RCM; **F)** Carotid artery disease (Stroke – TIA); **G)** Aortic calcification / Porcelain aorta; **H)** Recurrent pleural effusions
- **Prevention**: minimize dose to the heart; cardiac shielding; reduction of dose-volume; decreased field; breath-holding; treatment of conventional risk factors of CAD
- **Monitoring after chest radiation exposure**: TTE 5-10 years after exposure then re-assess every 5 years; consider stress-test for CAD detection

SPECIFIC CARDIAC COMPLICATIONS OF CHEMOTHERAPY

LV DYSFUNCTION: Anthracyclines (type I cardiotoxicity; permanent dose-dependant damage); Trastuzumab (type II cardiotoxicity; reversible damage; TTE every 3 months during therapy); Cyclophosphamide; Ifosfamide; Clofarabine; Docetaxel; Paclitaxel (in combination with Doxorubicin); Bevacizumab; Bortezomib; Dasatinib; Imatinib; Sunitinib

ISCHEMIA / VASOSPASM: Capecitabine; 5-Fluorouracil; Paclitaxel; Docetaxel; Bevacizumab (arterial thromboses); Rituximab; Dasatinib; Erlotinib; Sorafenib; Cisplatin; Carboplatin; Interferon

BRADYCARDIA: Thalidomide; Paclitaxel; Docetaxel

HTN: Cisplatin; Docetaxel; Bevacizumab; Rituximab; Trastuzumab; Dasatinib; Sunitinib; Sorafenib; Cyclosporine; Tacrolimus; MMF; Sirolimus

DEEP VEIN THROMBOSIS: Cisplatin; Thalidomide; Bevacizumab; Rituximab; Lenalidomide; Erlotinib; Sorafenib

↗ QT: Anthracyclines; Vorinostat; Arsenic tiroxide; Dasatinib; Lapatinib; Nilotinib; Sunitinib; Lenalidomide; 5-fluorouracil; Cyclophosphamide; Trastuzumab

6.10/ Permanent pacemaker (PPM) 233
6.11/ Cardiac resynchronization therapy (CRT) 239
6.12/ Implantable cardioverter-defibrillator (ICD) 241

6.1/ PHYSIOLOGY

MYOCARDIAL CELLS / HIS / PURKINJE	SINOATRIAL NODE / AV NODE
	 Inactivated rapid sodium channels (higher resting potential)
• **PHASE 4 (resting potential)**: -90 mV (extracellular Na+; intracellular K+) • **PHASE 0 (action potential)**: brief opening of rapid sodium channels (Na+ influx) • **PHASE 1**: inactivation of sodium channels and K+ efflux • **PHASE 2 (plateau)**: equilibrium between K+ efflux and Ca^{2}+ influx via slow calcium channels • **PHASE 3 (rapid repolarization)**: K+ efflux	• **PHASE 4 (rest)**: spontaneous depolarization → slow sodium influx via If sodium channel › **Intrinsic automaticity**: > 60 bpm (SA node) and 40-60 bpm (AV node) • **PHASE 0 (action potential)**: opening of slow calcium channels (Ca^{2}+ influx) • **PHASE 3 (repolarization)**: inactivation of calcium channels and potassium efflux

ARRHYTHMIC MECHANISMS

1) ABNORMAL AUTOMATICITY: ↗ phase 4 diastolic depolarization

2) REENTRY: two conduction pathways with different conduction velocities and refractory periods; requires one-directional conduction block in one of the pathways of the circuit

3) TRIGGERED ACTIVITY: abnormality during repolarization

› **Early afterdepolarization**: Torsade de pointes
› **Delayed afterdepolarization**: Digoxin poisoning; idiopathic VT; catecholaminergic polymorphic VT

6.2/ BRADYARRHYTHMIAS

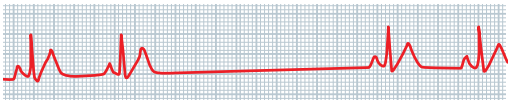
SINOATRIAL NODE

Sinus bradycardia

- **HR < 60 bpm; normal morphology of P wave**
- **Etiologies**: benign; vagal hypertonia; athletes; sick sinus syndrome (SSS); drugs (BB; CCB; Digoxin; Ivabradine; Clonidine; Propafenone; Amiodarone); post-cardiac surgery; ischemia / myocardial infarction; myocarditis; infiltrative cardiomyopathy; Lyme disease; coronary angiography; meningitis; intracranial hypertension; stroke; hypoxia; hypothyroidism; hypothermia; Gram-negative bacillus sepsis; cervical / mediastinal tumor; OSAHS; familial SSS (SCN5A mutation); Chagas, ...
- **Management**: observation; Atropine 0.5 mg; PPM if symptomatic

Sinus arrest / Sinus pause

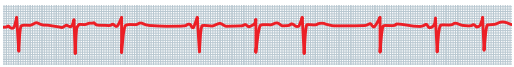
- **Sudden absence of sinus P wave; the duration of the pause is not a multiple of the intrinsic P–P interval**
  - › Ventricular asystole if absence of escape rhythm by latent pacemakers



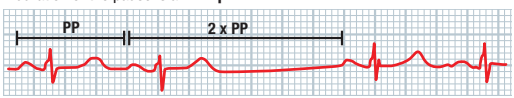
- **Etiologies**: ▸▸| Sinus bradycardia
- **Tachy-bradycardia syndrome**: supraventricular tachyarrhythmia alternating with sinus bradycardia; ± sinus pause following conversion of the tachyarrhythmia; associated with sick sinus syndrome (SSS)
- **Management**: PPM if symptomatic

Sinoatrial block (SA exit block)

- **Sinoatrial block, 2nd degree - Mobitz I**: progressive reduction of P-P interval then absence of P wave; duration of the pause < twice the P-P interval; group beating



- **Sinoatrial block, 2nd degree - Mobitz II**: sudden absence of P wave; the duration of the pause is a **multiple of the intrinsic P–P interval**



Wandering atrial pacemaker

- Passive and gradual shift from a dominant pacemaker focus of the sinoatrial node to a latent atrial pacemaker; a single pacemaker controls rhythm at any one time; possible shift of control back to the sinoatrial node
- **Mechanism**: vigorous vagal tone (benign phenomenon)

Chronotropic incompetence

- **Inability to achieve > 80% HRmax predicted during a stress test (in the presence of sufficient exercise)**
  - › **Chronotropic index**: observed HR reserve (HRmax on stress test - resting HR) / (HRmax predicted for age - resting HR); chronotropic incompetence if **< 80 %**
- **Consequences**: exercise intolerance; factor of poor prognosis

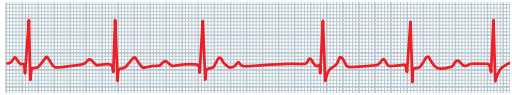
AV CONDUCTION: AV NODE / HIS–PURKINJE SYSTEM

First degree AV block

- **PR > 200 ms** in sinus rhythm
- **Narrow QRS**: delayed AV node conduction (↗ AH)
- **Wide QRS**: delayed AV node conduction (↗ AH) or His-Purkinje conduction (↗ HV)
  - › **Bifascicular block (RBBB + LAHB or RBBB + LPHB or LBBB)**: consider a lesion of the third branch in the presence of prolonged PR

2nd degree AV block, Mobitz I (Wenckebach)

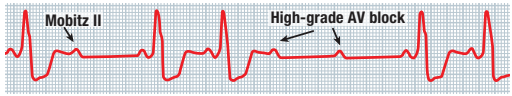
- **Progressive prolongation of the PR interval (with progressive shortening of the RR interval)** until a P wave is blocked; the RR interval including the non-conducted P wave is **less than twice the R–R interval of the previous cycle;** group beating



- **Prognosis**: benign (lesion involving the AV node in the majority of cases)
- **Treatment**: observation if asymptomatic

2nd degree AV block, Mobitz II

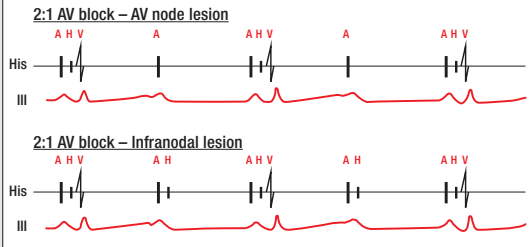
- **P wave suddenly blocked** without any previous prolongation of the PR interval; **the RR interval at the time of the non–conducted P wave = twice the PP interval**



- **Prognosis**: infranodal lesion (His-Purkinje system) in the majority of cases with **high risk of progression to complete AV block**
- **Treatment**: indication for PPM

2:1 AV block

- **P:QRS ratio = 2:1**
- **Suggests AV node lesion (benign)**: **A)** Wenckebach on another ECG; **B)** ↗ PR interval (but narrow QRS); **C)** Improvement of the block with exercise or atropine; **D)** Deterioration of the block with carotid sinus massage
- **Suggests infra-nodal lesion (requires PPM)**: **A)** Wide QRS (underlying intraventricular conduction disorder); **B)** Deterioration of the block with exercise or atropine; **C)** Improvement of the block with carotid sinus massage (↗ PP interval ⟶ ↗ His-Purkinje system recovery time)



High-grade AV block

- ≥ **2 successive P waves blocked** in sinus rhythm

Complete AV block (3rd degree)	• **Absence of AV conduction** • **Intranodal block**: junctional escape rhythm; narrow QRS; **HR 40–60 bpm** • **Infrahisian block**: ventricular escape rhythm (unreliable and unstable); wide QRS; **HR 15–40 bpm** • **Etiologies**: degenerative; drugs; congenital; ischemia - MI; vagal hypertonia; surgery; calcified AS; progressive familial heart block (Lenègre's disease; SCN5A or TRPM4 mutation); electrolyte disorders; myocarditis; endocarditis; tumor; Chagas; Lyme disease; rheumatoid nodule; AVR; TAVI; hypothyroidism; polymyositis; dilated cardiomyopathy (lamin A/C); infiltrative cardiomyopathy (amyloidosis; sarcoidosis; scleroderma); muscular dystrophy... • **Treatment**: Rule out a reversible cause; PPM

ELECTROPHYSIOLOGICAL STUDY OF CONDUCTION TISSUE

INDICATION: in the presence of a strong suspicion of significant and symptomatic bradyarrhythmia, but in the absence of a clearly documented abnormality

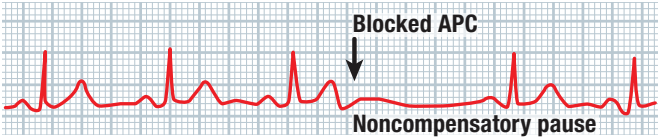
SNRT: Sinus node recovery time	• Continuous rapid atrial stimulation (30 s) then stopped • **SNRT**: interval between last paced beat and the first sinus return beat • **CSNRT (corrected SNRT)**: = SNRT - CL in sinus rhythm › **Normal CSNRT**: < 525 ms • Low sensitivity (65%) but high specificity (95%)
AV conduction	 **Intervals measured** • **AH**: AV node conduction; normal 55-125 ms • **His conduction time**: normal < 25 ms • **HV**: infra-His conduction time; normal: 35-55 ms › **HV > 100 ms**: possible risk of complete AV block › **Short HV**: **A)** Ventricular pre-excitation; **B)** PVC or idioventricular rhythm isorythmic with SR

6.3/ SUPRAVENTRICULAR TACHYARRHYTHMIAS

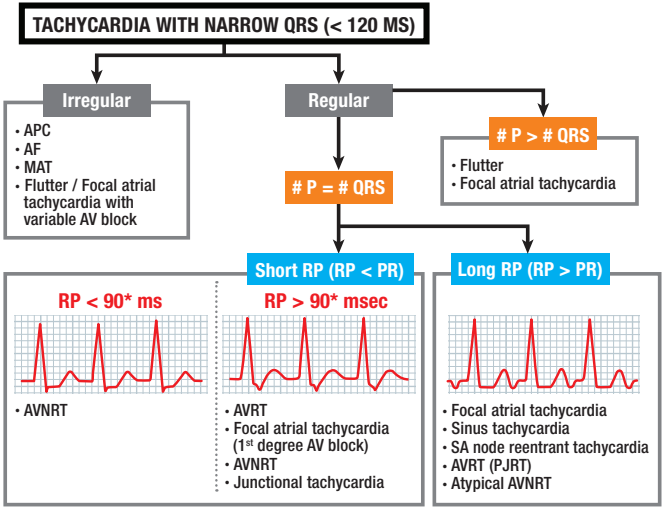
ATRIAL PREMATURE COMPLEXES

ATRIAL PREMATURE COMPLEXES (APC): premature P wave in the cardiac cycle; arises from an atrial focus outside of the sinoatrial node; different morphology from that of the sinoatrial node; sometimes situated in the T wave (look for abnormal morphology of the T wave)

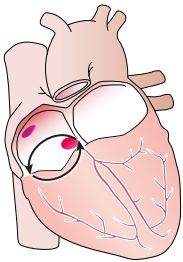
- **Modifiers**: Couplets; Bigeminy; Trigeminy; Salvo
- **Noncompensatory pause**: the APC depolarizes and **resets** the sinoatrial node; the interval between the two P waves before and after the APC **< twice the intrinsic PP interval**
- **Compensatory pause**: failure of the APC to depolarize the sinoatrial node; the interval between the two P waves before and after the APC = **twice the intrinsic PP interval**
- **Blocked atrial premature complex**: the P wave is not followed by a QRS complex (AV-His-Purkinje system in refractory period); the pause is usually noncompensatory



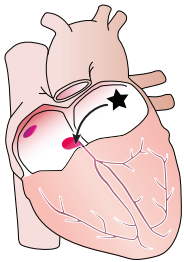
SUPRAVENTRICULAR TACHYARRHYTHMIAS



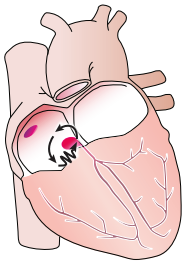
*70 msec for intracardiac VA interval (90 msec for surface ECG VA interval)



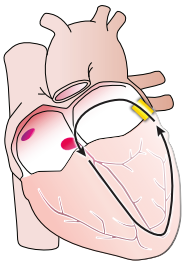
Atrial Flutter



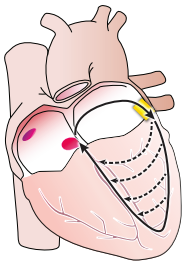
Focal atrial tachycardia



AVNRT: nodal reentry



Orthodromic AVRT



Antidromic AVRT

RESPONSE TO ADENOSINE (OR VAGAL MANEUVER)	
Sudden arrest	**Slowing then re–acceleration**
• AVNRT • AVRT • SA node reentrant tachycardia • (Focal atrial tachycardia)	• Sinus tachycardia • Focal atrial tachycardia • AF; Flutter • Nonparoxysmal junctional tachycardia

SINUS TACHYCARDIA

100-200 bpm (HRmax = 220 - age); nonparoxysmal (progressive onset and termination); normal P waves; secondary to sympathetic stimulation

ETIOLOGIES: fever / sepsis; hypotension; hyperthyroidism; anemia; anxiety; pain; exercise; hypovolemia; pulmonary embolism; ischemia; heart failure; shock; drugs (atropine; catecholamines; adriamycin); alcohol; cocaine; high output state; pregnancy

INAPPROPRIATE SINUS TACHYCARDIA: increased automaticity / sinus dysautonomia

› **Diagnosis**: sinus HR > 100 bpm at rest; mean 24-h HR > 90 bpm; diagnosis of exclusion (rule out physiological sinus tachycardia or focal AT from the high RA)

› **Management**: Rule out an underlying cause (anemia; hyperT4); Ivabradine; BB; radiofrenquency modification of sinoatrial node as last resort

POSTURAL ORTHOSTATIC TACHYCARDIA SYNDROME (POTS): orthostatic intolerance with significant increase of HR during the first 10 min after standing (HR > 120 bpm or HR increased by > 30 bpm)

› **Management**: fluids; NaCl; raise the head of the bed; training; elastic stockings; BB; Fludrocortisone; Midodrine; SSRI

SINOATRIAL NODAL REENTRANT TACHYCARDIA (SANRT): paroxysmal tachycardia; abrupt onset; P wave identical to P wave in SR

› **Management**: vagal maneuver; Adenosine; BB; CCB; RF ablation

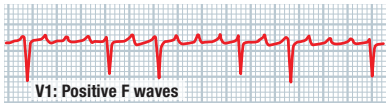
ATRIAL FLUTTER

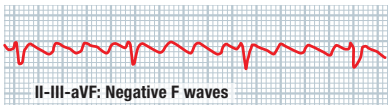
ATRIAL FREQUENCY: **300 bpm** (slowed by class IC AA with risk of 1:1 conduction)

VENTRICULAR FREQUENCY: **150 or 100 or 75 bpm** (2:1 or 3:1 or 4:1 conduction)

TYPICAL ATRIAL FLUTTER

- **Cavotricuspid isthmus-dependent macroreentrant flutter:** atrial flutter counterclockwise around the tricuspid valve annulus (most common) versus clockwise flutter
- **ECG:** sawtooth flutter waves (regular and identical); **negative waves in II-III-aVF and positive waves in V1 in counterclockwise flutter** (and vice versa in clockwise flutter); 2:1 or 3:1 or 4:1 AV conduction





MANAGEMENT

- ECV (50 J biphasic) or atrial overdrive or CCV (IV Ibutilide)
- AV node blocking agents (rate control more difficult than in AF)
- Class IC AAD (combined with AV node blocking agent) or class III AAD
- Thromboembolic prevention (▶▶| AF)
- **RF ablation of cavotricuspid isthmus**: success rate: 90-95%; **first-line long-term treatment;** target bidirectional block; 22-50% will have AF within 30 months

ATYPICAL ATRIAL FLUTTER

- **Cavotricuspid isthmus non-dependent macroreentrant flutter**

1) IART (intra-atrial reentrant tachycardia): macroreentrant circuit arising around a surgical scar following cardiac surgery

2) Left atrial flutter post-AF ablation

- **ECG**: variable morphology of flutter waves (depending on the circuit involved) and different from that of typical flutter
- **Management**: ECV; AV node blocking agents; AAD; RF ablation

FOCAL ATRIAL TACHYCARDIA

ATRIAL FREQUENCY: 150-250 bpm

THREE MECHANISMS: **A)** Automatic (incessant); **B)** Triggered activity; **C)** Microreentrant

ORIGIN: precise focus (pulmonary vein; atrial appendage; *crista terminalis;* SVC or IVC; coronary sinus; mitral annulus; fossa ovale)

ECG: **morphology of P wave different from that in SR**; isoelectric segment between P waves on all leads (unlike flutter); **long RP interval**

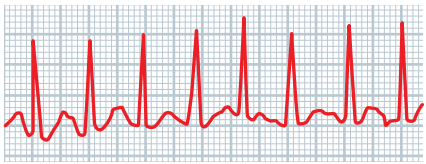
- **V1** - **Positive P wave**: = LA focus (negative P wave in aVL and I)
- **V1** - **Negative or biphasic P wave**: = RA focus (positive or biphasic P wave in aVL)

MANAGEMENT: AV node blocking agent; Class IC or III AAD; ablation of arrhythmogenic focus with 3D electroanatomic mapping (85% success)

MULTIFOCAL ATRIAL TACHYCARDIA (MAT)

ATRIAL FREQUENCY: **100-150 bpm**

IRREGULARLY IRREGULAR RHYTHM: absence of dominant pacemaker; variable morphology of P waves **(≥ 3 different morphologies)**; variable PR interval; abnormal automaticity



RISK FACTORS: COPD; age; Digoxin; Theophylline; hypomagnesemia

MANAGEMENT: correct underlying disease; nondihydropyridine CCB; Amiodarone; Mg^{2+}

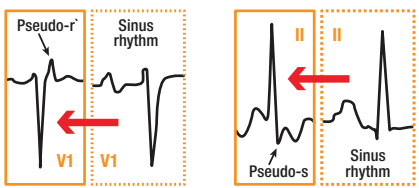
ATRIOVENTRICULAR NODAL REENTRANT TACHYCARDIA (AVNRT)

AVNRT: **150-250 bpm**; very regular rhythm (except at onset and termination)

ONSET: **sudden; APC with long PR interval (anterograde conduction via the slow pathway)**

SYMPTOMS: palpitations; anxiety; angina; syncope (↘ cardiac output; postconversion sinus pause; vasodepressive response)

TYPICAL AVNRT	ATYPICAL AVNRT
• **Anterograde conduction via the slow pathway; retrograde conduction via the fast pathway (with retrograde atrial activation)** • **ECG**: **Short RP < 90 ms; retrograde P wave hidden in the QRS or just after the QRS (pseudo-r' in V1; pseudo-S in II-III-aVF; absent on baseline ECG in sinus rhythm);** QRS *alternans* if very rapid	• 5-10 % • Anterograde conduction via the rapid pathway; retrograde conduction via the slow pathway; **long RP**



MANAGEMENT: vagal maneuver (Valsalva; carotid sinus massage); Adenosine; CCB; BB; ECV (50 J biphasic); class IC AAD (combined with AV node blocking agent); RF ablation

RF ABLATION: success rate > 95%; **first-line long-term treatment**

- **Ablation of slow pathway**: inferoposterior to AV node (between the septal aspect of the tricuspid valve annulus and the ostium of the coronary sinus)
- **Complications**: AV block (1%); recurrence (5%); tamponade

ATRIOVENTRICULAR REENTRANT TACHYCARDIA (AVRT) & ACCESSORY PATHWAY

AVRT: **150-250 bpm**; very regular rhythm (except at onset)

ACCESSORY PATHWAY (BUNDLE OF KENT): connection between atrium and ventricle (at the level of the AV sulcus) short-circuiting the AV node - His-Purkinje system; **retrograde conduction only or anterograde (and retrograde) conduction**

1) **Accessory pathway with retrograde conduction only (30%)**: hidden pathway; absence of preexcitation
   - **Associated arrhythmia**: orthodromic AVRT
2) **Accessory pathway with anterograde conduction (70%): ventricular pre-excitation; fusion of ventricular activations by the accessory pathway and by the AV - His-Purkinje system**
   - **Short or negative HV interval**
   - **Associated arrhythmias: A)** Orthodromic AVRT (retrograde conduction); **B)** Antidromic AVRT; **C)** Anterograde conduction of supraventricular arrhythmia (pre-excited AF)
   - **ECG**: PR < 120 ms; wide QRS (> 120 ms) with delta wave; ST-T abnormalities (opposite direction to the QRS); maximized pre-excitation when AV node in refractory period

	DELTA WAVE		
SITE OF PATHWAY	**V1**	**AVF**	**AVL**
Left lateral	+	+	-
Left septal or posterior	+	-	+
Right septal or posterior	-	-	+
Anterior or right lateral	-	+	+

WOLFF-PARKINSON-WHITE SYNDROME: symptoms compatible with tachyarrhythmia + ventricular pre-excitation

- **Benign pathway**: inefficient pathway with long refractory period; abrupt disappearance of pre-excitation on stress test (or intermittent loss during ECG or ambulatory monitoring)
- **Malignant pathway**: **refractory period < 250 ms**; able to maintain effective anterograde conduction of possible AF (with risk of VF and sudden death)

DEMONSTRATION OF AN ACCESSORY PATHWAY: **A)** Eccentric retrograde atrial activation during ventricular stimulation or during orthodromic AVRT; **B)** Ventricular stimulation during AVRT induces atrial activation even when the His bundle is refractory; **C)** Ventricular stimulation induces atrial activation before activation of the His bundle; **D)** Ventricular stimulation at various frequencies associated with a stable VA interval (non-decremental VA conduction)

ORTHODROMIC ATRIOVENTRICULAR REENTRANT TACHYCARDIA (AVRT)	ANTIDROMIC ATRIOVENTRICULAR REENTRANT TACHYCARDIA (AVRT) (5–10%)
• **Macro-reentrant tachycardia with anterograde conduction via the AV / His–Purkinje system and retrograde conduction via the accessory pathway** • **ECG**: Narrow QRS; retrograde P wave following QRS **(short RP but > 70 ms intra-cardiac)**; negative retrograde P wave in lead I if left lateral bundle	• **Macro-reentrant tachycardia with anterograde conduction via the accessory pathway and retrograde conduction via the AV / His-Purkinje system; wide QRS tachycardia** +
	• **If functional branch block ipsilateral to the accessory pathway:** ↗ VA interval and ↗ tachycardia cycle length	

MANAGEMENT OF AVRT: vagal maneuver; Adenosine (can precipitate AF); AV node blocking agent (can precipitate prexcited AF); ECV (50 J); AAD (IC; III); RF ablation of accessory pathway

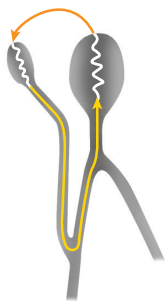
ABLATION OF THE ACCESSORY PATHWAY: **first-line long-term treatment**; success rate: 95%

› **Complications**: 5% recurrence rate; vascular access; microembolism / stroke (left pathway); tamponade; AV block; coronary lesion

› **Asymptomatic pathway**: **EP study or observation is reasonable (IIa recommendation);** ablation if high risk findings during EP study (**R-R < 250 ms** during induced AF; multiple accesory pathways; AVRT precipitating pre-excited AF; pathway with refractory period < 240 ms) or in patients with specific employment (e.g. pilot) +

PERMANENT FORM OF JUNCTIONAL RECIPROCATING TACHYCARDIA (PJRT): incessant supraventricular tachycardia; posteroseptal accessory pathway (R > L); pathway with **slow retrograde one-directional** conduction; **long RP**; **negative P wave in II-III-aVF** +

MAHAIM PATHWAY: accessory pathway in lateral wall of RV; distal connection to RV (atrioventricular connection) or to the right branch (atriofascicular connection); **similar conduction properties to those of the AV node (decremental conduction at higher HR); anterograde conduction only** +



MAHAIM PATHWAY

› **Baseline ECG**: normal (minimal pre-excitation)

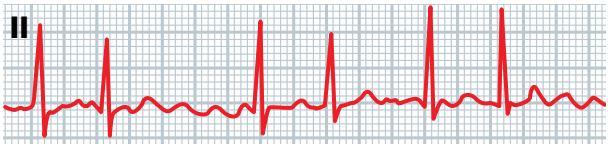
› **Associated arrhythmia**: antidromic AVRT (with **LBBB** morphology); QRS axis 0° and -75°; QRS < 150 ms; late precordial transition; HR 130-270 bpm

JUNCTIONAL TACHYCARDIA

NONPAROXYSMAL JUNCTIONAL TACHYCARDIA	PAROXYSMAL JUNCTIONAL ECTOPIC TACHYCARDIA (JET)
• 70-130 bpm; nonparoxysmal = progressive onset ("warm-up") • **Origin**: origin of AV node or His bundle; narrow QRS; abnormal automaticity • **Etiologies**: Digoxin poisoning; post-cardiac surgery; electrolyte disorder; ischemia; MI; COPD; hypoxia; myocarditis • **Management**: Treatment of underlying cause; BB; CCB	• 110-250 bpm; paroxysmal = sudden onset; more frequent in children; triggered by exercise or stress • **Origin**: AV node or His bundle; narrow QRS; AV dissociation versus VA association • **Management**: BB; AAD (IC; III); RF ablation

6.4/ ATRIAL FIBRILLATION

ATRIAL FREQUENCY: **400-600 bpm**; absence of organized P wave with chaotic atrial fibrillation-rhythm; irregularly irregular ventricular rhythm



› **Lead V1**: sometimes prominent fibrillatory waves (mimicking atrial flutter), but absence of organized waves elsewhere

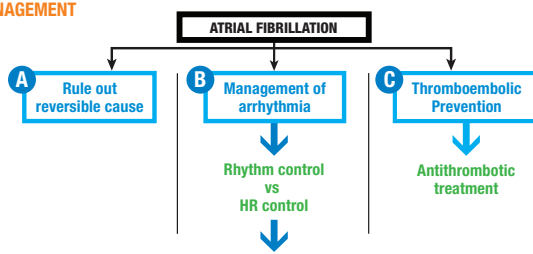
CLASSIFICATION

Paroxysmal AF	Terminates spontaneously or with intervention within < 7 days of onset
Persistent AF	Continuous AF, sustained > 7 days
Longstanding persistant AF	Continuous AF, sustained > 12 months
Permanent AF	No other attempt to restore and/or maintain SR
Nonvalvular AF	Absence of rheumatic MS, prosthetic heart valve or mitral valve repair

SYMPTOMS: palpitations; tiredness; dyspnea; exercise intolerance; faintness; syncope (conversion pause or rapid AF in the presence of structural heart disease); systemic embolism; heart failure (tachycardiomyopathy)

CCS SAF SCALE	
Class 0	Asymptomatic
Class I	Minimal effect on quality of life
Class II	Minor effect on quality of life
Class III	Moderate effect on quality of life
Class IV	Severe effect on quality of life

MANAGEMENT

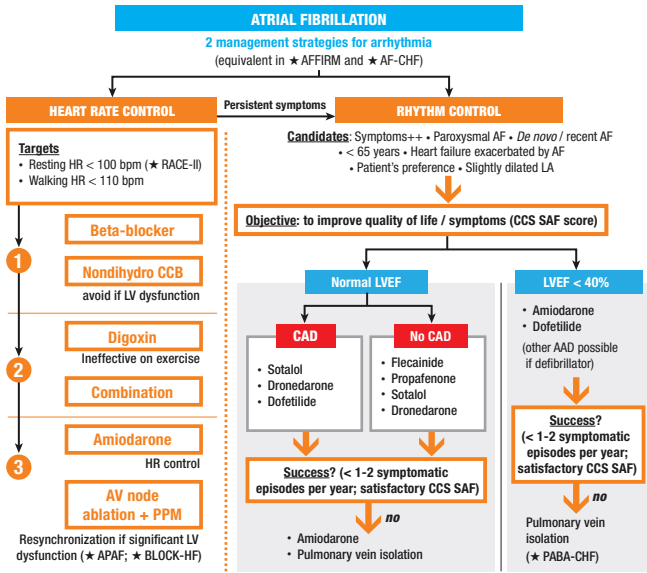


- Target improvement of quality of life and symptoms
- Reduce hospitalizations

RULE OUT REVERSIBLE CAUSE AND RISK FACTORS: Alcohol ("holiday heart syndrome"); ischemia; myocarditis - pericarditis; structural heart disease / heart failure / cardiomyopathy / valvular heart disease / LVH / congenital heart disease / diastolic dysfunction; supraventricular tachycardia (tachycardia-induced AF); SSS; WPW; HTN; pulmonary embolism; hyperthyroidism; frequent V-Pace; OSAHS; vagal hypertonia (athlete; sleep); hyperadrenergism (exercise); postoperative; pneumonia; PHT

› **AF in young patient with structurally normal heart**: consider electrophysiological study to eliminate other supraventricular arrhythmia degenerating to AF (tachycardia-induced AF)

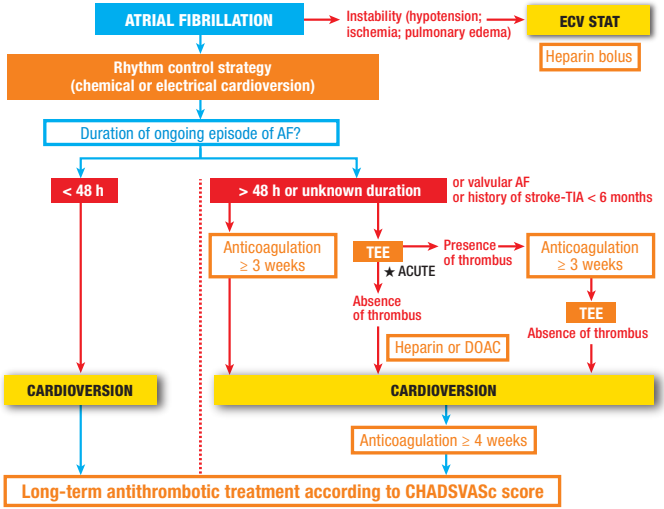
MANAGEMENT OF ARRHYTHMIA



HEART RATE CONTROL STRATEGY			
Diltiazem	0.25 mg/kg IV x 10 min (repeat 0.35 mg/kg PRN)	120 - 480 mg PO qd	Hypotension; bradycardia; edema; negative inotrope; avoid if ↘ LVEF or pre-excited AF
Verapamil	0.075 - 0.15 mg/kg IV x 2 min	120 - 240 mg PO bid	
Metoprolol	2.5 - 5 mg/kg IV x 2 min (3 doses every 5 min PRN)	25 - 200 mg PO bid	Hypotension; bradycardia; tiredness; depression; asthma; negative inotrope; avoid if preexcited AF
Nadolol	10 - 320 mg qd		
Esmolol	**IV bolus**: 500 µg/kg; **Infusion**: 50-300 µg/kg/min (dilution: 2500 mg / 250 mL)		
Digoxin	0.25 mg IV (or PO) every 6 h (4 doses over 24 h; adjustment according to creatinine clearance)	0.0625 to 0.25 mg qd	Digoxin toxicity; Nausea; Vomiting; Visual abnormalities; avoid in the presence of pre-excited AF
HEART RHYTHM CONTROL STRATEGY			
CLASS IC			
Flecainide	50 - 150 mg PO bid * Combine with AV node blocking agent	• **Efficacy at 1 year**: 30-50 % • **Adverse effects**: ↗ QRS (caution if > 25%); VT; bradycardia; 1:1 flutter • **Contraindications**: CAD or LV dysfunction (★ CAST) • Pre-treatment stress test if > 50 years or high Framingham score	
Propafenone	50 - 300 mg PO tid * Combine with AV node blocking agent		
CLASSE III			
Amiodarone	Loading dose of 10 g over several weeks then 100 - 200 mg PO qd	• **Efficacy at 1 year**: 60-70 % (★ CTAF) • **Avantage:** controls HR (BB effect) • **Adverse effects**: ▸▸| Amiodarone	
Dronedarone	400 mg PO bid	• **Efficacy at 1 year**: 40 % • ★ **ATHENA**: Paroxysmal AF; ↘ cardiac mortality with Dronedarone • **Contraindications:** heart failure / LVEF < 40% (★ ANDROMEDA) or permanent AF (★ PALLAS) or Digoxin • Monitor LFTs at 6 months	
Sotalol	40 - 160 mg PO bid	• **Efficacy at 1 year**: 30-50 % (★ CTAF) • **Adverse effects**: ↗ QT; torsade de pointes; bradycardia; asthma (BB effect) • **Avoid**: women > 65 years / CRF / LVEF < 40% / significant LVH / electrolyte disorders / ↗ QTc • Monitoring of QT for 72 h; stop if QTc > 500 ms	
Dofetilide	0.125 to 0.5 mg PO bid (according to CrCl)	• **Complication**: torsade de pointes • **Contraindications**: CrCl < 20 mL/min; hypokalemia; baseline QTc > 440 ms	

"PILL IN THE POCKET" APPROACH: AAD as needed (Flecainide 200 to 300 mg or Propafenone 450 to 600 mg) combined with Metoprolol 50 to 100 mg; indicated in the presence of occasional episodes in subjects with a healthy heart; initiate under cardiac monitoring to demonstrate safety of the approach

CARDIOVERSION



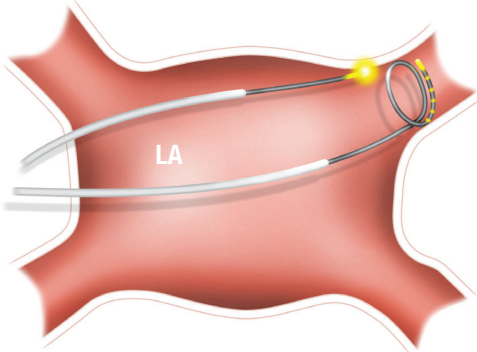
ELECTRICAL CARDIOVERSION: 200 J biphasic

- **Failure (5 %)**: Add AAD followed by another attempt of ECV (Amiodarone; Flecainide; Propafenone; Ibutilide; Sotalol)
- **Conversion then early recurrence of AF (ERAF) post-ECV**: Add AAD followed by another attempt of ECV

CHEMICAL CARDIOVERSION: only minimally effective when AF present for > 7 days

CHEMICAL CARDIOVERSION		
Propafenone	450 to 600 mg PO	• Hypotension; 1:1 flutter; bradycardia; complete AV block • Contraindicated in the presence of CAD or systolic dysfunction; administer with AV node blocking agent
Flecainide	200 to 300 mg PO	
Procainamide	15-17 mg/kg IV x 60 min	• Hypotension • **Efficacy**: 60 %
Ibutilide	1 mg IV x 10 min; may repeat once if necessary	• Torsade de pointes (2-3%) • Contraindicated if LVEF < 30% or significant LVH or ↗ QTc > 440 ms or SSS or hypokalemia • Pretreat with $MgSO_4$
Vernakalant	3 mg/kg x 10 min then observation for 15 min then 2nd bolus of 2 mg/kg x 10 min PRN	• Blocks various atrial ionic channels (↗ refractory period) • **Efficacy**: 50 % (★ ACT; ★ AVRO) • **Adverse effects**: dysgeusia; Nausea; Hypotension; ↗ QT and QRS intervals • **Contraindications**: hypotension; ACS during previous 30 days; NYHA III or IV; Severe AS; non-corrected QT > 440 ms; LVEF ≤ 35%

PULMONARY VEIN ISOLATION



PAROXYSMAL AF	PERSISTENT AF
• Triggered by **premature complexes arising in pulmonary veins** (90% of cases; ★ Haïssaguerre) • **Ablation:** pulmonary vein isolation (electrical disconnection from the rest of the LA by radiofrequency ablation)	• Presence of a substrate **maintaining and perpetuating the arrhythmia** • **Substrate**: structural and electrical remodeling of the atrium; fibrosis - inflammation - ↘ refractory period • **Ablation**: pulmonary vein isolation combined with modification of the substrate (other radiofrequency lesions in the atria) › Linear ablation (roof of LA and mitral annulus; ± cavotricuspid isthmus) › Ablation of complex fractionated atrial electrograms sites (CFAE) › No benefit in ★ STAR-AF

OBJECTIVE: improve symptoms and quality of life

INDICATION: **AF with persistent and harmful symptoms (negative impact on quality of life) despite trial of drug treatment (class I or III AAD)**

SUCCESS RATE: **60-75% after 1 procedure and 75-90% after 2 procedures** (success rate 10-15% lower in the presence of persistent AF); improvement of quality of life; more effective than AAD for maintenance of SR

MAJOR COMPLICATIONS: **5 %;** vascular complication (1-2%); cardiac perforation / tamponade (1%); thromboembolism (1%); PV stenosis (0.5%); atrio-esophageal fistula; phrenic nerve palsy (diaphragmatic paralysis); atypical flutter; death (1/1,000)

CONTRAINDICATIONS: LA > 55 mm; significant structural heart disease; LA thrombus; long-term AF; mechanical MVR

PERIPROCEDURAL CONSIDERATIONS: TEE before the procedure; procedure performed under anticoagulation (continue warfarin; stop DOAC 12-24 h before the procedure); continue anticoagulation for 2 months post-op (then according to CHADSVASc score)

› **Early recurrence of AF post-PVI (< 3 months)**: secondary to acute inflammation; management by rhythm control then re-evaluate at 3 months

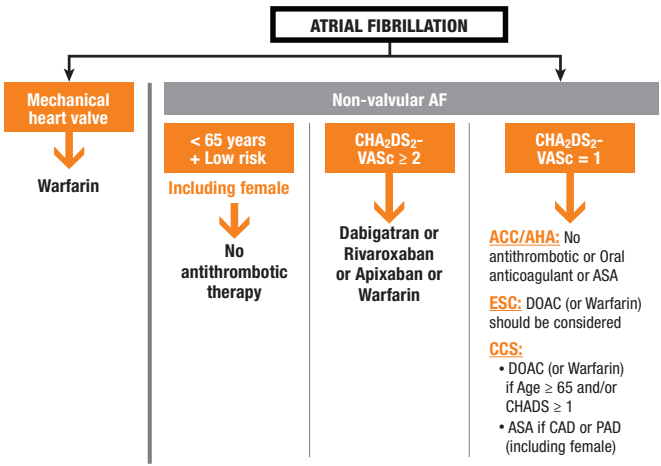
PVI FOR PERSISTENT AF AND HEART FAILURE: more effective than AV node ablation + resynchronization (★ PABA-CHF)

- ★ **AATAC-AF:** PVI superior to Amiodarone in relieving persistent AF in patients with congestive heart failure; PVI associated with ↘ all-cause mortality and ↘ hospitalization

SURGICAL ABLATION OF AF: indicated for symptomatic AF when concomitant cardiac surgery is planned

- **Paroxysmal AF: pulmonary vein isolation** (endocardial or epicardial) ± ablation line to mitral annulus
- **Persistent AF: modified Cox-Maze procedure**; requires bilateral atriotomy; ablation lines in LA to isolate pulmonary veins / isolate the posterior LA / create an ablation line between the pulmonary veins and mitral annulus; ablation lines at the cavotricuspid isthmus and between inferior and superior venae cavae; left atrial appendectomy; one-year success rate: 85% (63% in ★ CTSN AF)

THROMBOEMBOLIC PREVENTION



$CHADS_2$ SCORE		
Congestive heart failure and/or LVEF ≤ 40%	1 point	**Stroke / year** 0 → 1.9 % 1 → 2.8 % 2 → 4.0 % 3 → 5.9 % 4 → 8.5 % 5 → 12.5 % 6 → 18.2 %
HTN	1 point	
≥ 75 years	1 point	
DM	1 point	
Stroke – TIA – Thromboembolism	2 points	

Gage BF, Waterman AD, Shannon W, et al. JAMA 2001;285:2864-70.

CHA_2DS_2-VASC SCORE		
Recent decompensated HF and/or LVEF ≤ 40%	1 point	**Stroke / year** 0 → 0 % 1 → 1.3 % 2 → 2.2 % 3 → 3.2 % 4 → 4.0 % 5 → 6.7 % 6 → 9.8 % 7 → 9.6 % 8 → 6.7 % 9 → 15.2 %

BENEFIT OF WARFARIN IN PRIMARY PREVENTION: ★ AFASAK-1 AND 2;★ SPAF-1 and 2 and 3; ★ BAATAF; ★ CAFA; ★ SPINAF

- **Benefit of Warfarin**: **relative risk of stroke ↘ by 64%**
- **Benefit of ASA**: relative risk of stroke↘ by 19%

WARFARIN ANTIDOTE: vitamin K; prothrombin complex concentrate (Octaplex; Beriplex; Cofact; Proplex; factors II - VII - IX - X); FFP (8 units)

★ **ACTIVE-A**: Warfarin impossible; ASA + Plavix vs ASA; ↘ stroke but ↗ major bleeding

- **Indication for ASA-Clopidogrel**: when any form of oral anticoagulation is impossible but acceptable bleeding risk

BLEEDING RISK ASSOCIATED WITH ANTICOAGULATION

WARFARIN: **annual risk of major bleeding ≈ 3%**

HAS-BLED SCORE		
HTN (SBP > 160 mmHg)	1 point	**Major bleeding/year** 0 → 1.1 % 1 → 1.02 % 2 → 1.88 % **3 → 3.74 %** 4 → 8.7 % 5 → 12.5 %
Abnormal (liver or renal function) • Creatinine ≥ 200 µmol/L or Dialysis • AST - ALT > 3 x ULN or Bilirubin 2 x ULN or Cirrhosis	1 point each	
Stroke	1 point	
Bleeding (history; Anemia; Bleeding diathesis)	1 point	
Labile INR	1 point	
Elderly (> 65 years)	1 point	
Drugs (associated with a risk of bleeding) or Alcohol	1 point each	

Pisters R, Lane DA, Nieuwlaat R, et al. Chest 2010;138:1093-100.

HAS-BLED ≥ 3: **high bleeding risk**; try to correct reversible risk factors

OTHER SCORES: $HEMORR_2HAGES$; ATRIA

DIRECT ORAL ANTICOAGULANTS (DOAC)

CONTRAINDICATED: **A)** Mechanical prosthetic valve; **B)** Moderate to severe mitral stenosis (usually of rheumatic origin)

DABIGATRAN (PRADAXA)	RIVAROXABAN (XARELTO)	APIXABAN (ELIQUIS)	EDOXABAN (SAVAYSA; LIXIANA)
Direct thrombin inhibitor	Direct factor Xa inhibitor	Direct factor Xa inhibitor	Direct factor Xa inhibitor
Dose: 150 mg bid • **110 mg bid**: ≥ 75 years; CrCl 30-49 mL/min with additional bleeding risk factor Not studied in patients with CrCl < 30 mL/min	**Dose: 20 mg qd** • **15 mg qd**: CrCl 30-49 mL/min Not studied in patients with CrCl < 30 mL/min	**Dose: 5 mg bid** • **2.5 mg bid**: ≥ 2 factors (≥ 80 years or ≤ 60 kg or creatinine ≥ 133 µmol/L) Not studied in patients with CrCl < 25 mL/min	**Dose: 60 mg qd** • **30 mg qd**: CrCl 30-49 mL/min Not studied in patients with CrCl < 30 mL/min
★ **RELY** • **150 mg bid**: ↘ **stroke (superior to warfarin);** comparable bleeding • **110 mg bid:** non-inferior for stroke; ↘ **bleeding**	★ **ROCKET-AF** • 20 mg (15 mg if CrCl 30-49 mL/min): **non-inferior to warfarin for stroke**; comparable bleeding	★ **ARISTOTLE** • Apixaban 5 mg bid (2.5 mg bid not extensively studied): ↘ **stroke (superior to warfarin);** ↘ **bleeding;** ↘**all-cause mortality**	★ **ENGAGE-AF** • **60 mg qd**: **non-inferior for stroke** (trend for superiority); ↘ **bleeding** • **30 mg qd**: **non-inferior for stroke** (trend for inferiority); ↘ **bleeding;** ↘ **all-cause mortality**
Renal excretion: 80%	Renal excretion: 33%	Renal excretion: 25%	Renal excretion: 50%

FOLLOW-UP: CrCl (Cockcroft-Gault) prior to initiation / when clinically indicated / ≥ 1 x / year

CONSIDER REDUCED DOSE: high bleeding risk (HAS-BLED ≥ 3); impaired renal function; drug interactions (P-gp and/or CYP3A4)

★**AVERROES**: AF with mean CHADS = 2; Warfarin impossible; Apixaban 5 mg bid versus ASA; early discontinuation (↘ stroke with Apixaban; similar bleeding)

BLEEDING WITH DOAC: Idarucizumab (Dabigatran; ★ RE-VERSE); Andexanet alpha (Rivaroxaban; Apixaban; Edoxaban); discontinue the anticoagulant; local compression; plasma expansion / transfusion; maintain diuresis to promote elimination; seek an opinion from a hematologist / pharmacist; consider prothrombin complex concentrates or activated factor VII or hemodialysis (Dabigatran)

DOAC AND OTHER ANTICOAGULANTS	
Switch from Warfarin → DOAC	• INR < 2.0 → Start DOAC immediately • INR 2.0 - 2.5 → Start DOAC on the following day
Switch from IV Heparin → DOAC	After stopping heparin
Switch from LMWH → DOAC	At the next scheduled dose of LMWH
Switch from DOAC → LMWH or IV Heparin	At the next scheduled dose of DOAC
Switch from DOAC → Warfarin	Stop DOAC when INR > 2.0

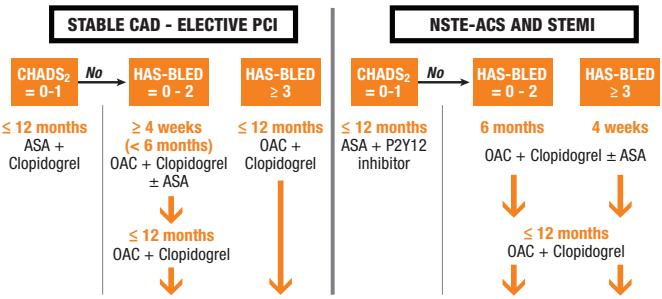
PERIOPERATIVE USE OF DOAC	
Surgery with low bleeding risk (Dental extraction; cataract; endoscopy without biopsy; superficial skin surgery)	Continue DOAC (operate under DOAC) or skip the dose in the morning of the operation
Surgery with intermediate bleeding risk (Endoscopy with biopsy; prostate or bladder biopsy; angiography; electrophysiological intervention; pacemaker)	• **Apixaban – Rivaroxaban:** stop DOAC ≥ 24 h before the operation • **Dabigatran**: stop DOAC ≥ 24 h (CrCl ≥ 80 mL/min) or ≥ 36 h (CrCl 50-80 mL/min) or ≥ 48 h (CrCl 30-50 mL/min)
Surgery with high bleeding risk (Lumbar puncture; spinal / epidural surgery; thoracic / abdominal / neurological / orthopedic surgery; liver or kidney biopsy; TURP)	• **Apixaban – Rivaroxaban**: stop DOAC ≥ 48 h before the operation • **Dabigatran**: stop DOAC ≥ 48 h (CrCl ≥ 80 mL/min) or ≥ 72 h (CrCl 50-80 mL/min) or ≥ 96 h (CrCl 30-50 mL/min)

PERCUTANEOUS OCCLUSION OF LEFT ATRIAL APPENDAGE

★**PROTECT AF**: Watchman system non-inferior to warfarin for thromboembolic prevention; associated procedural complications; requires long-term antiplatelet therapy

INDICATION: high risk of stroke (CHADS ≥ 2) for whom anticoagulation is precluded

ATRIAL FIBRILLATION AND CORONARY ARTERY DISEASE



Beyond 12 months

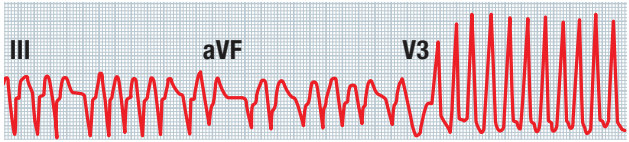
Long term oral anticoagulation

OAC (Oral anticoagulation):
Either Warfarin (INR 2.0 - 2.5) or DOAC (Dabigatran 110 mg bid; Rivaroxaban 15 mg qd; Apixaban 2.5 mg bid)

Proton pump inhibitor if risk of GI bleeding

★**WOEST:** 573 patients with an indication for anticoagulant therapy undergoing PCI (25-30% with ACS); Warfarin + Clopidogrel (versus Warfarin + Clopidogrel + ASA) associated with ↘ bleeding and ↘ mortality

PRE-EXCITED ATRIAL FIBRILLATION



Irregularly irregular tachycardia with wide QRS

COMPLICATIONS: **rapid AV conduction via an efficient accessory pathway (refractory period < 250 ms) → transformation to VF** +

MANAGEMENT: ECV stat; Procainamide or Ibutilide if hemodynamically stable; ablation of accessory pathway

› **Agents contraindicated**: AV node blocking agents predisposing to conduction via the accessory pathway (Digoxin; nondihydropyridine CCB; BB; Adenosine; IV Amiodarone)

AF DETECTED BY PACEMAKER (SUBCLINICAL AF)

★ **ASSERT**: detection of subclinical atrial tachycardia (defined by HR > 190 bpm and duration > 6 min) associated with increased thromboembolic risk

› **Episode > 17.7 h (upper quartile of duration)**: **significantly ↗ risk of stroke (fivefold)**

★ **TRENDS**: atrial tachycardia (probable AF) ≥ 5.5 h associated with increased thromboembolic risk

CONSIDER ANTICOAGULATION: **A)** Episode lasting ≥ 24 h; **B)** Shorter episode in high-risk patient (cryptogenic stroke; TIA)

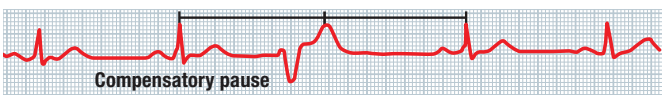
6.5/ VENTRICULAR TACHYARRHYTHMIAS

PREMATURE VENTRICULAR COMPLEXES

Premature ventricular depolarization during the cardiac cycle; wide QRS; T wave in opposite direction to the QRS

MODIFIERS: couplet; bigeminy; trigeminy; monomorphic; polymorphic; associated with compensatory or noncompensatory pause; associated with retrograde atrial activation; interpolated complex; fusion complex; associated with echo (PVC → retrograde atrial activation → anterograde ventricular activation)

› **Compensatory pause**: **interval between QRS before and after PVC = 2 x RR interval** (failure of PVC to reset the sinoatrial node)



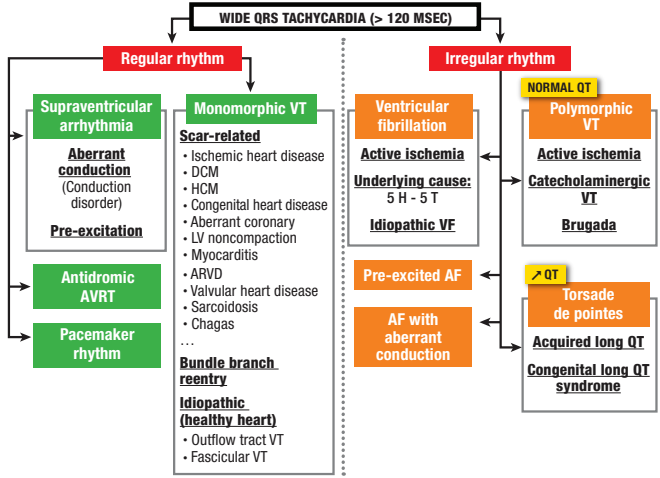
› **Interpolated PVC**: PVC between two beats of baseline rhythm with no modification of rhythm

PVC / MONOMORPHIC NSVT IN STRUCTURALLY NORMAL HEART: benign; risk of **tachy-cardiomyopathy** if frequent **(> 10,000 / 24 h)** and with a short coupling interval (< 300 ms) +

MANAGEMENT: Observation; intervention if symptoms or complications (tachycardiomyopathy); BB; AAD (IC; III); radiofrequency ablation

PVC ASSOCIATED WITH AF: elements in favor of PVCs rather than aberrant conduction → fixed coupling interval / pause after wide QRS / bigeminy

WIDE QRS TACHYCARDIA: DIFFERENTIAL DIAGNOSIS



WIDE QRS TACHYCARDIA: VT VERSUS ABERRANT CONDUCTION

	QRS	V1–V2	V6
RBBB morphology	QRS > 140 ms Left frontal axis	R RSr' QR	R/S < 1 QS
LBBB morphology	QRS > 160 ms Right frontal axis	notch at S R > 30 ms R to S > 70 ms	Any Q wave

OTHER CRITERIA

- **Supraventricular tachycardia with aberrant conduction**: **A)** Onset: Early P wave (APC); **B)** Change of PP interval precedes change of RR interval; **C)** QRS: identical to baseline rhythm; **D)** Stopped by vagal maneuver
- **Ventricular tachycardia**: **A)** Onset: Early QRS (PVC); **B)** Change of RR interval precedes change of PP interval; **C)** QRS: identical to PVC on baseline rhythm; **D)** Canon A wave; variable intensity of S1; variable SBP; **E)** -90° to 180° axis deviation

LOCALIZATION OF VT ON ECG

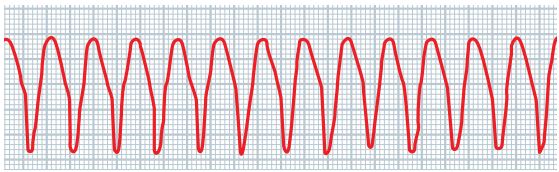
1) **V1 morphology**: LBBB (VT arises in RV and sometimes in LV septum); RBBB (VT arises in LV)
2) **Frontal axis**: Superior (VT arises in inferior wall); Inferior (VT arises in anterior wall)
3) **QRS V1 to V6**: **A)** Positive concordance → basal focus; **B)** Early QRS transition (V1-V2) → apical focus; **C)** Late QRS transition → midventricular focus
4) **QS complexes**: indicate the territory in which the arrhythmia arises (II-III-aVF = inferior; V4-V5-V6 = apical)
5) **Epicardial VT**: pseudo-Delta wave (initial portion of wide QRS)

VENTRICULAR TACHYCARDIA (VT)

≥ 3 consecutive ventricular complexes; HR 110-250 bpm

- **Sustained**: **> 30 s (or ECV necessary)** +
- AV dissociation or VA association (retrograde conduction)

MONOMORPHIC VENTRICULAR TACHYCARDIA: **scar-related in the majority of cases; look for structural heart disease** +



- **Acute management**: cardioversion (100 J biphasic) / defibrillation if absent pulse (200 J biphasic); Procainamide or Amiodarone (150 mg IV x 10 min then 1 mg/min x 6 h then 0.5 mg/min x 18 h) or Sotalol; ventricular overdrive; look for underlying cause
- **Secondary prevention**: First-line ICD; BB; Amiodarone (★ OPTIC); Sotalol; Mexiletine; RF ablation if repeated ICD shocks

VENTRICULAR TACHYCARDIA IN STRUCTURALLY NORMAL HEART

▸▸| Idiopathic ventricular tachycardia

BUNDLE BRANCH REENTRY TACHYCARDIA: **in DCM; macro-reentry with anterograde conduction via the right bundle branch and retrograde conduction via the left bundle branch; Monomorphic VT with LBBB morphology**

- **Management**: right bundle branch ablation

ACCELERATED IDIOVENTRICULAR RHYTHM (AIVR): **50-110 bpm; competition between sinoatrial node and a ventricular ectopic focus**; increased automaticity; progressive onset and termination; associated with MI / reperfusion or Digoxin toxicity

- **Management**: observer; atropine PRN; « overdrive » auriculaire

POLYMORPHIC VENTRICULAR TACHYCARDIA WITH NORMAL QT: **occurs during active myocardial ischemia or in genetic arrhythmia syndrome** (▸▸| Channelopathies)

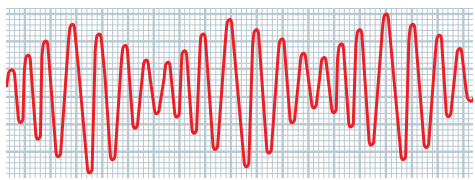
- **Acute management**: defibrillation; Rule out active ischemia; BB; Amiodarone; Lidocaine; correct electrolyte disorders

IDIOPATHIC MONOMORPHIC VENTRICULAR TACHYCARDIA

Absence of structural heart disease; favorable prognosis

Outflow tract VT	**MECHANISM**: myocyte calcium overload inducing triggered activity (delayed afterdepolarization); NSVT > sustained VT; 140-180 bpm; induced by exercise / stress / Isoproterenol **RVOT VT**: **LBBB morphology; inferior frontal axis; V3-V4 precordial transition** › **DDx**: ARVD (abnormal SAECG / TTE / EPS) › **Management**: Adenosine; BB; Verapamil; class IC AAD; RF ablation (90% success rate)  **LVOT VT**: 2 morphologies on ECG **1) RBBB - Inferior axis - S in V6** **2) LBBB - Inferior axis - early precordial R wave transition (V2 LVOT versus ≥ V3 RVOT)** **VT ARISING IN SINUS OF VALSALVA**: **LBBB; inferior axis** › **Left sinus of Valsalva**: rS in I; V1 with "w" pattern or notch; early precordial transition › **Right sinus of Valsalva**: large R wave in V1; early precordial transition
Fascicular VT	**MECHANISM**: reentry in Purkinje system **3 TYPES**: › **Left posterior hemibranch**: **RBBB; Left superior frontal axis** › **Left anterior hemibranch**: RBBB; Right inferior frontal axis › **High septum**: Narrow QRS; normal axis **MANAGEMENT**: Verapamil / Diltiazem; class III AAD; RF ablation
Mitral annulus	**ECG**: RBBB morphology; Dominant R in precordial leads

TORSADE DE POINTES



Polymorphic ventricular tachycardia; HR 200-250 bpm; twisting of QRS around the isoelectric line (axis changes by 180° every 5-20 beats)

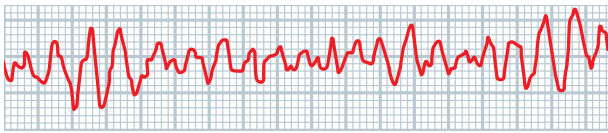
- **Associated with ↗ QT interval**: **prolonged ventricular repolarization; QT > 500 ms; ± prominent U wave** +
- **Mechanism**: triggered activity (early afterdepolarization)
- **Long RR - short RR sequence**

ETIOLOGIES - ACQUIRED LONG QT: Drugs (www.qtdrugs.org); AAD (IA; III); severe bradycardia; electrolyte disorders (hypokalemia; hypomagnesemia); CNS lesion; ischemia; hypothermia; anorexia; hypothyroidism; heart failure

- **Congenital long QT syndrome**: ▸▸| Channelopathies

MANAGEMENT: Mg^{2+} (1-2 g IV); ventricular overdrive; Isoproterenol (pause-dependent TdP); Lidocaine; BB with temporary pacemaker in place; correct underlying cause / correct electrolyte disorders; PPM (in the case of pause-dependent TdP)

VENTRICULAR FIBRILLATION (VF)



Chaotic ventricular rhythm; HR 400-600 bpm; absence of organized QRS - ST - T; fatal within 3-5 min

ACUTE MANAGEMENT: immediate defibrillation (200 J biphasic) ± CPR (▸▸| Chapter 9); rule out ischemia; look for underlying cause ("5 H and 5 T"); AAD to prevent recurrence (Amiodarone; Lidocaine; Procainamide)

- **5 H - 5 T**: Hypovolemia; Hypoxia; Hydrogen (acidosis); Hypokalemia / Hyperkalemia; Hypothermia; Tension pneumothorax; Tamponade; Toxin; coronary Thrombosis; pulmonary Thrombosis

ELECTRICAL STORM: **≥ 3 episodes of VT/VF in 24 hours** +

- **Management**: first-line BB; intubation / sedation; rule out ischemia or underlying cause; magnet over the ICD if inappropriate shocks; Amiodarone or Procainamide or Lidocaine (in the presence of ischemia); ventricular overdrive; reprogramming of ICD therapies; RF ablation; ventricular mechanical support

IDIOPATHIC VENTRICULAR FIBRILLATION

DIAGNOSIS OF EXCLUSION: absence of structural heart disease and absence of an identifiable channelopathy

EARLY REPOLARIZATION (HAÏSSAGUERRE PATTERN): association between VF and early repolarization (J point elevation ≥ 1 mm on 2 contiguous inferior and/or lateral leads)

POSSIBLE MECHANISM: triggered by PVC with short coupling interval (arising in Purkinje system)

MANAGEMENT: ICD; Isoproterenol for electrical storm; Quinidine; cathter ablation of PVCs triggering VF; assessment of first-degree relatives

6.6/ CHANNELOPATHIES

CONGENITAL LONG QT SYNDROME (LQTS)

ABNORMAL QT: **QTc ≥ 450 ms (male) or ≥ 460 ms (female)**

› **50th percentile of LQTS cohorts**: **QTc > 480 ms** +

TRANSMISSION: autosomal dominant form (Romano-Ward syndrome) or recessive form (deafness; Jervell & Lange-Nielsen syndrome)

SCHWARTZ SCORE		
ECG	**Clinical features**	**Family history**
• QTc ≥ 480 ms: 3 points • QTc 460-479 ms: 2 points • QTc > 450-459 ms (male): 1 point • QTc after 4 min of recovery on stress test ≥ 480 ms: 1 point • TdP: 2 points • Alternating T wave: 1 point • Notched T wave on 3 leads: 1 point	• Syncope on exercise / stress: 2 points • Syncope without stress: 1 point	• Family member with LQTS: 1 point • Sudden death in first degree relative before the age of 30 years: 0.5 point

≤ 1 point: low probability
1.5 to 3 points: intermediate probability
≥ 3.5 points: high probability

Schwartz PJ, Moss AM, Vincent GM, et al. Circulation 1993; 88: 782-784.

LQT1	LQT2	LQT3
KCNQ1 mutation	KCNH2 mutation	SCN5A mutation
Trigger: exercise; swimming; stress	**Trigger**: noise / alarms; postpartum	**Trigger**: rest / sleep
Wide-based T wave	Notched or biphasic T wave	Long isoelectric segment then narrow-based T wave Management: first-line BB (significant protection); ± ICD	**Management**: BB (moderate protection); ± ICD	**Management**: Mexiletine; Flecainide; Ranolazine; Low protection by BB; ± ICD

COMPLICATIONS: syncope; TdP; sudden death

MANAGEMENT: avoid trigger; avoid drugs that ↗ QT; correct electrolyte; avoid strenuous exercise; BB (first-line); DDD or AAI pacemaker for pause-dependent TdP (especially associated with LQT3); sympathectomy

› **Risk factors for sudden death**: syncope; QTc > 500 ms; complex ventricular arrhythmia; Jervell and Lange-Nielsen

› **ICD**: **A)** Secondary prevention of sudden death; **B)** Syncope on BB therapy

SHORT QT SYNDROME (SQTS)

ECG: **QTc interval ≤ 340 ms with HR < 100 bpm;** high amplitude T wave; short or absent ST segment +

COMPLICATIONS: AF; syncope; VF; sudden death

DIFFERENTIAL DIAGNOSIS: hyperkalemia; hypercalcemia; hyperthermia; acidosis; Digoxin

MANAGEMENT: Quinidine; Sotalol; ICD for secondary prevention

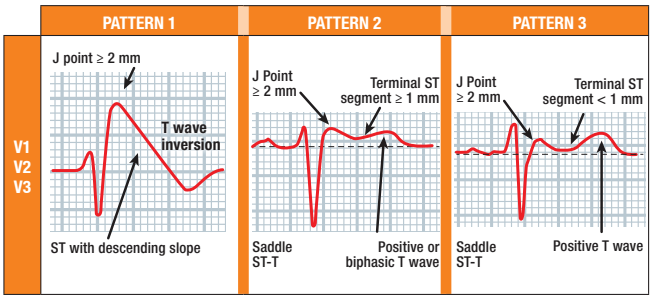
BRUGADA SYNDROME

TRANSMISSION: autosomal dominant; sodium channel gene mutation (SCN5A; 20% of patients) or unidentified mutation

DIAGNOSTIC CRITERIA

• Pattern 1 on ECG (≥ 2 leads: V1-V2-V3); spontaneous or with drug challenge (sodium channel blocking agent) or • Pattern 2 or 3 (≥ 2 leads: V1-V2-V3) with conversion to Pattern 1 with drug challenge	+	**≥ 1 CLINICAL CRITERIA** • Polymorphic VF or VT • Family history of sudden death < 45 years • Pattern 1 in the family • VT during programmed stimulation • Unexplained syncope • Nocturnal agonal respiration

Wilde AA, Antzelevitch C, Borggrefe M et al. Circulation 2002; 106; 2514-2519.



UNMASKED BRUGADA SYNDROME: sodium channel blocking agent (challenge with Procainamide 10 mg/kg IV x 10 min or Flecainide 400 mg PO); Drugs (www.brugadadrugs.org); fever; hypokalemia or hyperkalemia; leads V1-V2-V3 in 2nd or 3rd intercostal space; Cocaine; alcohol

COMPLICATIONS: Polymorphic VT (triggered by rest / sleep) / VF; sudden death (particularly in men in their forties); AF; SSS; conduction disorder

MANAGEMENT: Quinidine and/or Isoproterenol for electrical storm

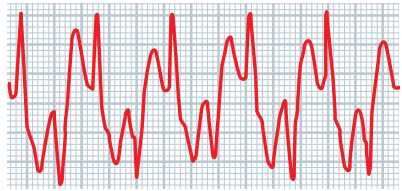
› **ICD**: **A)** Secondary prevention of sudden death; **B)** Spontaneous pattern 1 with syncope

CATECHOLAMINERGIC POLYMORPHIC VT

TRANSMISSION: autosomal dominant (ryanodine receptor gene mutation - RyR2) or autosomal recessive (calsequestrin gene mutation - CASQ2)

MYOCYTE CALCIUM OVERLOAD: triggered activity with delayed afterdepolarization

PRESENTATION: Polymorphic VT induced by exercise / stress; bidirectional VT



DIAGNOSIS: structurally normal heart; normal ECG

› **Exercise** → bidirectional VT and/or polymorphic PVCs and/or polymorphic VT

MANAGEMENT: BB (first-line treatment; Nadolol 1-2 mg/kg); CCB (Verapamil); Flecainide; Sympathectomy; avoid vigorous exercise

› **Titration of drug treatment**: guided by stress test and Holter

› **ICD**: **A)** Secondary prevention of sudden death; **B)** Syncope on BB therapy

GENETIC TESTING FOR FAMILIAL ARRHYTHMIAS

OBJECTIVE: **A)** Family screening; **B)** Establish / confirm a diagnosis

DISEASE	GENE	INDICATIONS FOR GENETIC TESTING
Long QT syndrome	Identification of a causal mutation: 75% (KCNQ1; KCNH2; SCN5A; KCNE1; KCNE2)	a) Cardiac arrest + long QT (family screening) b) Syncope + long QT (family screening / diagnosis / treatment) c) Asymptomatic long QT (family screening / diagnosis / treatment)
Brugada syndrome	Identification of a causal mutation: 20% (SCN5A)	a) Cardiac arrest + Brugada syndrome (family screening) b) Syncope + Brugada syndrome (family screening) c) Asymptomatic + Pattern 1 (family screening)
ARVD – Arrhythmogenic RV dysplasia	Identification of a causal mutation: 50% (PKP2; DSP; ± DSG2 - DSC2)	a) ARVD satisfying diagnostic criteria (family screening) b) Suspected ARVD (diagnostic criterion)
Catecho-laminergic polymorphic VT	Identification of a causal mutation: 50% (RYR2; ± CASQ2)	Suspected catecholaminergic polymorphic VT (family screening)
Hypertrophic cardiomyopathy	Identification of a causal mutation: 50% (MYH7; MYBPC3; ± TNNT2 - TNNI3 - TMP1)	a) HCM with clinical diagnosis (family screening) b) HCM with pre-excitation (PRKAG2; LAMP2; GLA)
Familial dilated cardiomyopathy	Identification of a causal mutation: 20 % (MYBPC3; MYH7; TNNT2; LMNA; SCN5A)	a) Probable familial DCM (family screening) b) Familial DCM + high-grade conduction disorder / atrial arrhythmia: LMNA and SCN5A
Sudden death	**Indication for targeted genetic testing**: negative autopsy in the presence of familial clinical signs of a particular phenotype (for family screening)	

6.7/ SYNCOPE

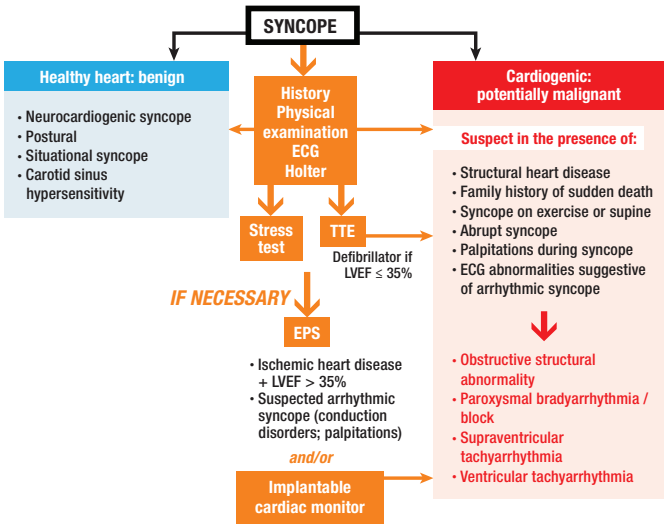
Brief loss of consciousness secondary to transient global cerebral hypoperfusion; resolves spontaneously; rapid recovery

DDX OF LOSS OF CONSCIOUSNESS: Syncope; Aborted cardiac arrest; Epilepsy; Conversion / Psychogenic; Ischemic (vertebrobasilar TIA); Migraine; Metabolic disorder (Hypoglycemia; Poisoning; Hypoxemia; Hyperventilation); Traumatic (cerebral commotion)

DDX OF SYNCOPE: **A)** Neurocardiogenic (vasovagal); **B)** OH (dysautonomia; drugs; dehydration; alcohol); **C)** Cardiogenic syncope; **D)** Carotid sinus hypersensitivity; **E)** Situational syncope (cough; defecation; laughing; micturition; postprandial; deglutition); **F)** Subclavian steal syndrome

DDX OF CARDIOGENIC SYNCOPE: Bradyarrhythmia / Block (AV block; SSS; pause following conversion of supraventricular tachyarrhythmia); Tachyarrhythmia (supraventricular; AF; WPW syndrome; VT; channelopathy; arrhythmogenic drugs; idiopathic VF); Obstructive valvular heart disease; Aortic dissection; Myxoma; Tamponade; HCM; Infarction / Ischemia; Congenital coronary artery anomalies; Massive pulmonary embolism; PHT; Pacemaker dysfunction

ASSESSMENT



Rare syncope and definitive diagnosis necessary

ASSESSMENT: History of the present illness; Physical examination; BP supine - standing; carotid sinus massage; ECG; Holter (weekly syncope) or Loop recorder (monthly syncope); TTE

ECG ABNORMALITIES SUGGESTIVE OF ARRHYTHMIC SYNCOPE: diurnal sinus bradycardia < 40 bpm or diurnal sinus pauses ≥ 3 s; bifascicular block; QRS > 120 ms; Mobitz II or 3rd degree AV block; pre-excitation; NSVT; long QT; short QT; Brugada pattern; epsilon wave / T wave inversion in V1-V2-V3; early repolarization; LVH (dilated cardiomyopathy or HCM); Q waves

ELECTROPHYSIOLOGICAL STUDY: placement of intracardiac catheters to evaluate: **A)** sinoatrial node function (rule out SSS); **B)** AV node and His-Purkinje system function (rule out AV block); **C)** susceptibility to supraventricular and ventricular tachyarrhythmias

- **Indications (syncope)**: **A)** Ischemic heart disease not meeting the criteria for ICD; **B)** Conduction disorder with suspected arrhythmic syncope (not meeting the criteria for permanent pacemaker); **C)** Abrupt syncope or preceded by palpitations with suspicion of an arrhythmic cause
- **Look for**: **A)** CSNRT > 525 ms; **B)** HV interval > 100 ms; **C)** Infra-His block during RA stimulation; **D)** Induced supraventricular tachycardia with hypotension; **E)** Monomorphic VT induced during programmed ventricular stimulation in the presence of ischemic heart disease
- **Programmed ventricular stimulation**: runs of 8 successive impulses (CL between 600 and 400 ms) then 1 or 2 or 3 premature complexes (minimal coupling interval of 200 ms)

ORTHOSTATIC HYPOTENSION (OH)

DEFINITION: **reduction of SBP > 20 mmHg or DBP >10 mmHg on standing up (< 3 min)** +

ETIOLOGIES: Drugs; Dehydration / Hemorrhage; Postprandial; Dysautonomia

- **Primary dysautonomia**: **A)** Pure dysautonomia (Bradbury-Eggleston syndrome); **B)** Multi-system atrophy (Shy-Drager syndrome); **C)** Parkinson's disease
- **Secondary dysautonomia**: DM; amyloidosis; alcohol; CRF; age; Guillain-Barré; mixed connective tissue disease; RA; Eaton-Lambert syndrome; SLE; carcinomatous autonomic neuropathy; multiple sclerosis; Wernicke's encephalopathy; hypothalamic or mesencephalic neoplastic or vascular disease; hereditary neuropathy; HIV; Chagas; Syphilis; botulism; Fabry; Tangier; vitamin B12 deficiency; porphyria; spinal cord lesion

MANAGEMENT: education; stand up slowly; lie down in the case of symptoms; sodium supplement (NaCl 1-2 g tid) and adequate hydration (2-3 L per day); avoid hypotensive drugs / alcohol; elastic compression stockings; Midodrine (alpha-agonist; 2.5-10 mg tid); Fludrocortisone (mineralocorticoid; 0.1-0.3 mg qd); raise the head of the bed by 10° to decrease nocturnal diuresis

NEUROCARDIOGENIC SYNCOPE (VASOVAGAL)

PRESENTATION: Trigger factor (prolonged standing or emotional stress) → prodromal symptoms preceding syncope (nausea; diaphoresis; blurred vision; palpitations; faintness) → brief syncope

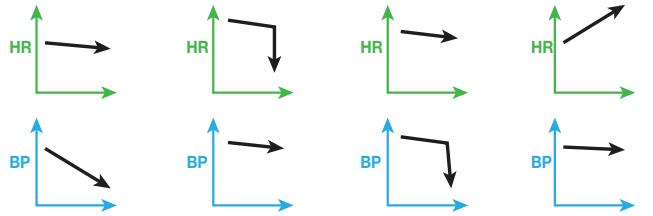
MECHANISM: vigorous ventricular contraction in the presence of low preload (secondary to venous pooling) → activation of cardiac mechanoreceptors → vagal hypertonia

- **Three responses to vagal hypertonia**: **A)** Cardioinhibitory (sinus pause and/or AV block); **B)** Vasodepressor; **C)** Mixed

TILT TABLE TEST: indication → to confirm the diagnosis of neurocardiogenic syncope when in doubt

- **Procedure**: 20 min in horizontal supine position → 30 to 45 min at 70° (± Isoproterenol or TNT)
- **Look for**: syncope + type of response following vagal hypertonia

MANAGEMENT: education; avoid trigger factors; sodium supplement (1-2 g NaCl tid) and adequate hydration; elastic compression stockings (30 mmHg); avoid hypotensive drugs / alcohol; isometric counterpressure maneuvers (handgrip for 2 min; leg crossing) or supine position in the case of prodromal symptoms; orthostatic training; raise the head of the bed by 10°; Midodrine / BB / Fludrocortisone / SSRI (Fluoxetine; Paroxetine; Venlafaxine); consider DDD pacemaker in the case of refractory syncope with dominant cardioinhibitory response (no benefit in ★ VPS-II; positive results in ★ ISSUE-3)



CAROTID SINUS HYPERSENSITIVITY

CAROTID SINUS MASSAGE: Apply pressure with 2 fingers (circular movements) for 10 s over the carotid pulse (at the level of the cricoid cartilage) with cardiac monitor

- **Contraindications**: carotid murmur; history of TIA - stroke
- **Cardioinhibitory response**: ventricular asystole > 3 s during massage → indication for DDD or VVI pacemaker in a patient with syncope

6.8/ ANTIARRHYTHMIC DRUGS (AAD)

VAUGHAN WILLIAMS CLASSIFICATION		
CLASS IA – SODIUM CHANNEL BLOCKING AGENTS		
	• Slow phase 0 (↘ conduction velocity) • Prolong the duration of the action potential (↗ QT) • Intermediate kinetics • Act on atria / ventricles / accessory pathway	
Quinidine	• **Indications**: Atrial and ventricular arrhythmias; Brugada; short QT syndrome; Idiopathic VF • **Dose**: 6 to 10 mg/kg IV (0.3-0.5 mg/kg/min); 300 to 600 mg PO qid	• ↗ QRS (avoid ↗ > 25 %) • ↗ QT (TdP) • Hypotension; Nausea; Vomiting; Diarrhea; Thrombocytopenia; Lupus; Fever; Arrhythmogenic
Procainamide	• **Indications**: Atrial and ventricular arrhythmias; CCV AF (combined with AV node blocking agent); Pre-excited AF • **Dose**: 15-20 mg/kg IV x 60 min (max 1 g) then 2 to 6 mg/min IV; stop if hypotension / ↗ QRS > 50% / arrhythmia controlled	• **Metabolite**: N-acetylprocainamide (class III effect; renal elimination) • **Adverse effects**: ANA+; drug Lupus; Arrhythmogenic; Infra-His block; ↗ QT (torsade de pointes); Negative inotropic agent with high-dose; Hypotension
Disopyramide	• **Indications**: Atrial and ventricular arrhythmias; HCM • **Dose**: 100-300 mg PO tid to qid	• Negative inotropic agent • Vagolytic effect (↗ heart rate) • Urinary retention; constipation; ↗ QT (TdP)

CLASS IB – SODIUM CHANNEL BLOCKING AGENTS		
	• Decrease the duration of the action potential • Rapid kinetics • Main effect: ventricular	
Lidocaine	• **Indications**: Ventricular arrhythmias; (enhanced effect in ischemic tissues) • **Dose**: 1 to 3 mg/kg IV (20-50 mg/min) then 1-4 mg/min (dilution: 2 g / 500 mL D5%)	• CNS toxicity (faintness; paresthesia; confusion)
Mexiletine	• **Indications**: Ventricular arrhythmias; long QT syndrome 3 • **Dose**: 150 to 300 mg PO bid to tid	• Sinus bradycardia; hypotension • CNS toxicity (dysarthria; faintness; paresthesia; confusion)
CLASS IC – SODIUM CHANNEL BLOCKING AGENTS		
	• Slow phase 0 (↘ conduction velocity) • Slow kinetics • **Use-dependent effect**: maximum antiarrhythmic effect at high HR (receptor open or inactivated) • ↗ **QRS duration** (avoid ↗ > 25 %) especially at high HR	
Flecainide	• **Indications**: AF; Flutter; PSVT; catecholaminergic polymorphic VT • **Dose**: 50 to 200 mg bid (combine with AV node blocking agent)	• Avoid in patients with CAD (★ CAST) / LV dysfunction • Risk of organization of AF into flutter with 1:1 AV conduction • Negative inotropic agent • ↗ pacemaker stimulation threshold
Propafenone	• **Indications**: AF; Flutter; PSVT • **Dose**: 150 to 300 mg PO bid to tid (in combination with AV node blocking agent)	• Avoid in CAD / LV dysfunction • Hepatic metabolism (7% of patients are slow metabolizers) • Negative inotropic agent • ↗ pacemaker stimulation threshold
CLASS II – BETA–BLOCKERS		
Beta-blockers	• Block beta-adrenergic receptors • **Indications**: supraventricular and ventricular arrhythmias • **Metoprolol**: 2.5 to 5 mg IV every 5 min x 3 • **Esmolol**: 0.5 kg /mg IV bolus then 50-200 µg/kg/min (dilution: 2500 mg/250 mL)	• **Adverse effects**: Negative inotropic agent; bronchospasm; hypotension; bradycardia; block; rebound effect on discontinuation; depression; exacerbation of severe PAD; masking of hypoglycemia symptoms; nightmares; erectile dysfunction

CLASS III – POTASSIUM CHANNEL BLOCKING AGENTS		
	• Increase the duration of the action potential; minimal effect on phase 0 • ↗ QT interval (risk of TdP)	
Amiodarone	• **Indications**: AF; Flutter; VT; VF; PSVT • **Dose**: 150 mg IV x 10 min then 1 mg/min IV x 6 h then 0.5-1 mg/min thereafter (dilution: 450 mg/250 mL D5%) • **PO**: 800 to 1600 mg PO daily x 7-14 days (10 g) then 100 to 600 mg daily • **Adverse effects**: ▸▸| Amiodarone	
Sotalol	• **Indications**: AF; PSVT; ventricular arrhythmias • **Dose**: 80 to 160 mg bid	• ↗ QT (TdP) • **Inverse use-dependent**: maximum antiarrhythmic effect at lower HR (resting receptors); ↗ QT at low HR • ★ **SWORD**: ↗ mortality post-myocardial infarction with LVEF ≤ 40% with d-Sotalol (without BB effect) • Renal excretion
Dronedarone	• **Indications**: Paroxysmal AF (★ ATHENA) • **Dose**: 400 mg bid	• **Contraindication**: NYHA III-IV heart failure (★ ANDROMEDA); permanent AF (★ PALLAS); liver disease
Dofetilide	• **Indications**: AF and Flutter • **Dose**: 0.125 to 0.5 mg PO bid	• ↗ QT (initiate in hospital; avoid if baseline QTc ≥ 440 ms) • Renal excretion • Safe in CAD or LV dysfunction (★ DIAMOND)
Ibutilide	• **Indications**: CCV of AF and Flutter (success: 70%) • **Dose**: 1 mg x 10 min (with $MgSO_4$; repeat x 1 PRN	• ↗ QT - TdP; Monitoring x 8 h post-dose • Contraindicated if QTc > 440 ms or hypokalemia
CLASS IV – CALCIUM CHANNEL BLOCKING AGENTS		
	• Decrease conduction velocity (phase 0) of SA and AV nodes	
Verapamil and Diltiazem	• **Indications**: PSVT; AF Flutter (rate control); fascicular VT • **Diltiazem**: 0.25 mg/kg IV x 2 min (2nd bolus after 15 min); 120-360 mg PO daily	• Negative inotropic agent (avoid in the presence of LV dysfunction) • Hypotension; Bradycardia; Leg edema; Drug interactions

OTHER AAD		
Digoxin	• ↗ Vagal tone • **Indications**: Rate control of HR in AF (at rest) • **Dose**: loading dose of 0.5 to 1 mg x 24 h (PO or IV) then 0.0625 to 0.25 mg PO daily	• **Toxicity**: calcium overload → delayed afterdepolarization / ↗ automaticity • ▶▶| Chapter 9 - Digoxin poisoning • Renal excretion
Adenosine	• Brief inhibition of AV conduction • **Indications**: PSVT; VT RVOT • **Dose**: Adenosine: 6 to 12 mg rapid IV	• **Adverse effects**: precipitates AF (1-15%); flushing; dyspnea; retrosternal chest pain • **Contraindications**: asthma; theophylline • **Transplant recipient or Dipyridamole**: use a dose of 3 mg
Atropine	• Vagolytic • **Indications**: symptomatic bradycardia • **Dose**: 0.5 to 1 mg IV (up to 2 mg)	

6.9/ AMIODARONE

ADVERSE EFFECTS

Pulmonary toxicity (2%)	**Toxicity correlated with cumulative dose** • Interstitial lung disease; Organizing pneumonia / BOOP; ARDS • Cough; Dyspnea; Fever • **PFT:** ↘ DLCO / restrictive pattern • **HDCT**: Interstitial / alveolar opacities; Ground glass; Fibrosis • **Diagnosis of exclusion** (rule out infection and heart failure)	• Permanently discontinue Amiodarone • Corticosteroids if severe • Slow improvement (long half-life of amiodarone)
GI toxicity (30%)	• Nausea; Anorexia; Constipation • ↗ AST ALT 2 x ULN • Symptomatic hepatitis (3%) - Cirrhosis	• Rule out DDx • Consider discontinuation
Hypothyroidism (20%)	• ↗ TSH and ↘ Free T4 • **Risk factors**: Female; underlying autoimmune thyroid disease (positive antibody); failure to escape from the Wolff-Chaikoff effect	• L-Thyroxine • Continue Amiodarone
Hyperthyroidism (10 %)	• ↘ TSH and ↗ Free T4 • ↗ INR if treated with warfarin • Thyroid scintigraphy falsified by the iodine load of Amiodarone **Etiologies** **a)** ↗ **T4 synthesis**: Underlying thyroid disease (Graves; multinodular goiter) exacerbated by iodine load **b)** ↗ **T4 release**: Destructive thyroiditis (fever; painful gland); hypothyroid phase several weeks or months later **c) Mixed** (majority)	**According to etiology** **a)** PTU or Methimazole; Discontinue Amiodarone once hyperthyroid symptoms have been controlled (as Amiodarone blocks conversion of T4→T3) **b)** Prednisone; ± Discontinue Amiodarone **c)** Corticosteroids + antithyroid drugs (then stop antithyroid drugs if good response to corticosteroids in ≤ 1 week of treatment)

Skin	• Photosensitivity (up to 75%) • Blue discolouration (< 10%)	• Avoid exposure to sunlight
CNS	Ataxia; Paresthesia; Polyneuritis; Tremor	Dose-dependent effect
Ophtalmic	Halo; Optic neuropathy; Photophobia; Blurred vision; Corneal microdeposits	Discontinue Amiodarone in the presence of optic neuropathy
Cardiac	Bradycardia; Block; Arrhythmogenic (< 1%); ↗ **defibrillation threshold**; ↘ tachycardia CL	

MAJOR DRUG INTERACTIONS: Digoxin; Procainamide; Disopyramide; Diltiazem; Flecainide; Phenytoin; Cyclosporine; Simvastatin; Atorvastatin

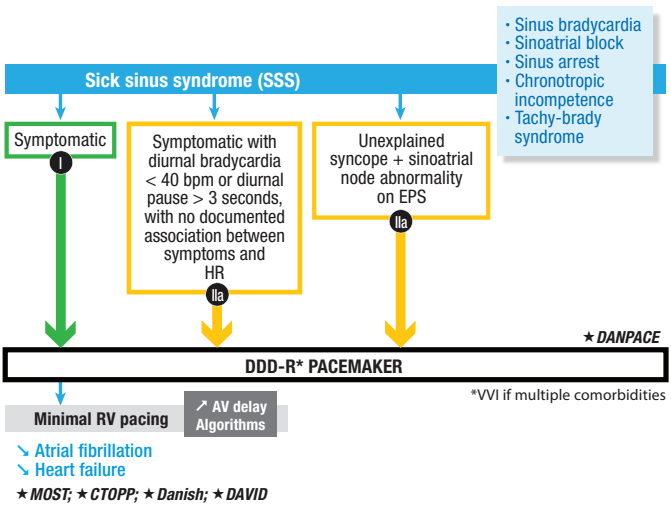
› **Warfarin**: **it is recommended to decrease the dose of warfarin by 30-50% on initiation of Amiodarone**

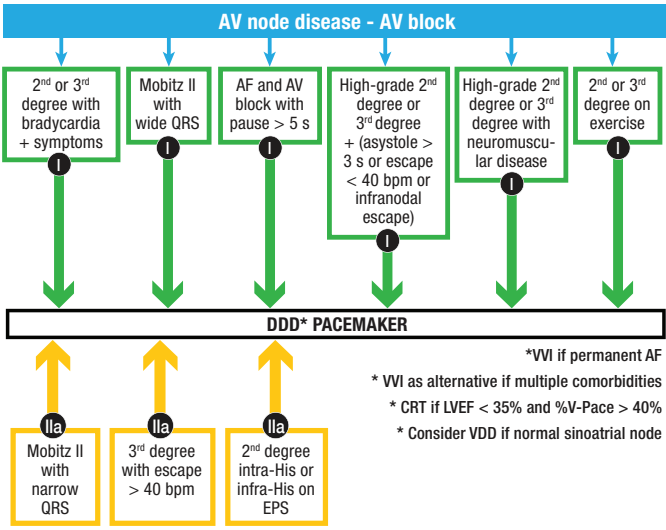
WORK-UP BEFORE STARTING AMIODARONE: TSH - Free T4 - T3; LFTs; CXR; Ophthalmological examination if underlying abnormalities; renal function; ECG

FOLLOW-UP ANALYSES: TSH - Free T4 every 6 months; AST / ALT every 6 months; annual CXR

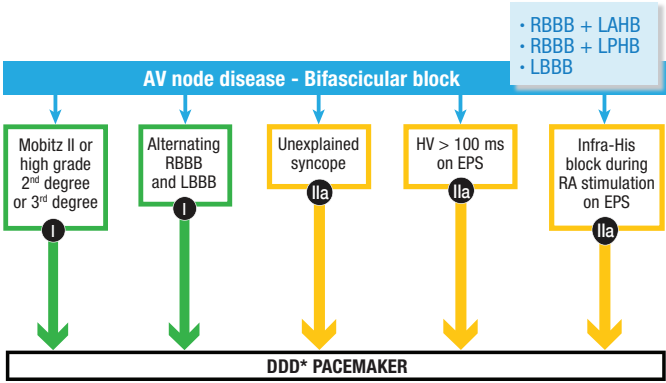
6.10/ PERMANENT PACEMAKER (PPM)

INDICATIONS

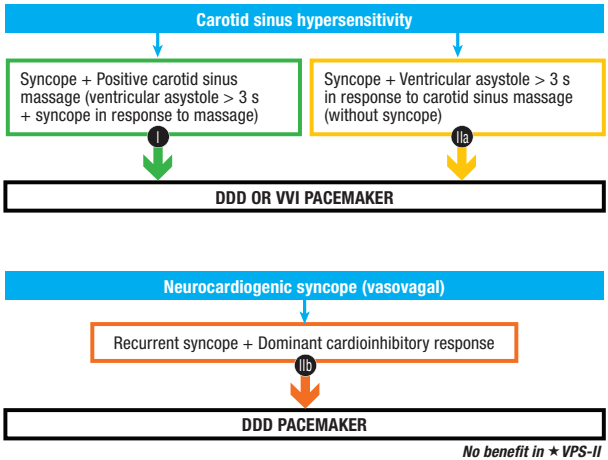




AV node disease - AV block
2nd or 3rd degree with bradycardia + symptoms
I
Mobitz II with wide QRS
I
AF and AV block with pause > 5 s
I
High-grade 2nd degree or 3rd degree + (asystole > 3 s or escape < 40 bpm or infranodal escape)
I
High-grade 2nd degree or 3rd degree with neuromuscular disease
I
2nd or 3rd degree on exercise
I
DDD* PACEMAKER
IIa
Mobitz II with narrow QRS
IIa
3rd degree with escape > 40 bpm
IIa
2nd degree intra-His or infra-His on EPS
*VVI if permanent AF
* VVI as alternative if multiple comorbidities
* CRT if LVEF < 35% and %V-Pace > 40%
* Consider VDD if normal sinoatrial node



• RBBB + LAHB
• RBBB + LPHB
• LBBB
AV node disease - Bifascicular block
Mobitz II or high grade 2nd degree or 3rd degree
I
Alternating RBBB and LBBB
I
Unexplained syncope
IIa
HV > 100 ms on EPS
IIa
Infra-His block during RA stimulation on EPS
IIa
DDD* PACEMAKER
*VVI if permanent AF
* VVI as alternative if multiple comorbidities
* CRT if LVEF < 35% and %V-Pace > 40%



TYPES OF PERMANENT PACEMAKERS

NBG CODE				
-1- Chamber paced	**-2- Chamber sensed**	**-3- Response to sensing**	**-4- Rate modulation**	**-5- Multisite pacing**
• O = None • A = Atrium • V = Ventricle • D = Dual (A + V)	• O = None • A = Atrium • V = Ventricle • D = Dual (A + V)	• O = None • T = Triggered • I = Inhibited • D = Dual (T + I)	• O = None • R = Rate modulation	• A = Atrium • V = Ventricle • D = Dual (A + V)

AAI: atrial pacing at the lower rate limit in the absence of sensing of an atrial event; indicated in sick sinus syndrome with preserved AV conduction

VVI: ventricular pacing at the lower rate limit in the absence of sensing of a ventricular event; absence of atrioventricular synchrony; indicated in AV block with permanent AF

DDD: atrial and ventricular pacing; atrial and ventricular sensing; indicated in AV block

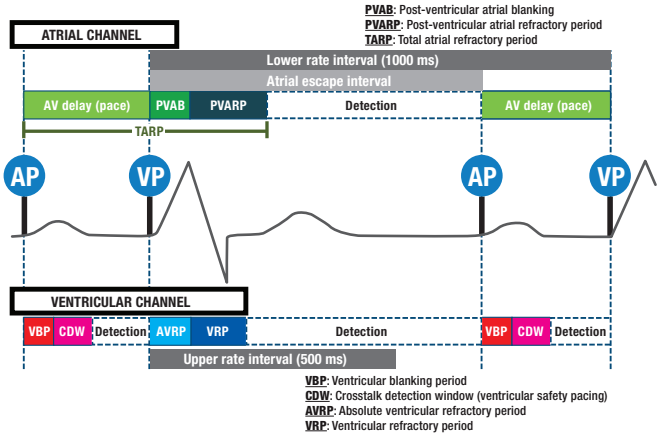
- **4 possibilities**: **A)** A-Sense / V-Sense; **B)** A-Sense / V-Pace (at the end of the AV interval in the absence of sensing of a ventricular event); **C)** A-Pace / V-sense (A-Pace at the end of the atrial escape interval in the absence of sensing of an atrial event); **D)** A-Pace / V-Pace
- **AV delay**: set a long AV delay (not exceeding 250-300 ms) to promote intrinsic AV conduction and minimize ventricular pacing
  - **A-Pace / V-Pace delay > A-Sense / V-Pace delay** (A-Sense: part of the atrium is already depolarized)

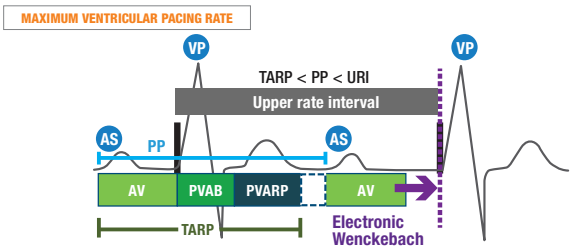
VOO: asynchronous ventricular pacing; mode used in pacemaker-dependent patients submitted to a source of electromagnetic interference (e.g.: electrocautery)

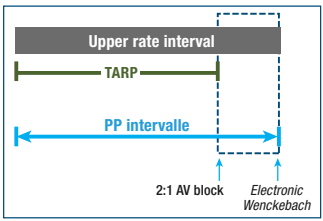
VDD: ventricular pacing with preserved atrioventricular synchrony on sensing of intrinsic P waves; requires a single lead (proximal atrial sensing by a ring; bipolar distal ventricular lead); consider in AV block in the absence of sick sinus syndrome

DDI: absence of "tracking" of sensed atrial events; V-Pace when the "lower rate interval" is reached (and A-Pace when the atrial escape interval is reached in the absence of a sensed event); indicated for atrial tachyarrhythmia with ineffective "mode-switch"

DDD PACEMAKER INTERVALS







RULE : Upper rate interval ≥ TARP

- **If PP interval < URI**
  → electronic Wenckebach
- **If PP interval < TARP** → 2:1 AV block
  - Frequency of 2:1 AV block
    = 60,000 ms / TARP (ms)

SPECIAL FUNCTIONS / ALGORITHMS

RATE ADAPTIVE: DDD-R or AAI-R or VVI-R; increased pacing rate when the patient is active (via activity sensor); activate in the case of symptomatic chronotropic incompetence / sick sinus syndrome

HYSTERESIS: **lower rate interval following V-Sense longer than lower rate interval following V-Pace (e.g.: 50 bpm vs 70 bpm);** promotes intrinsic rhythm

AAI ⟷ DDD MODE (MVP MODE): AAI mode switches to DDD mode when ≥ 2 of the previous 4 A-A intervals do not contain V-Sense

DYNAMIC AV DELAY: AV delay decreases at higher HR **(= ↘ TARP);** useful in patients with AV block and risk of 2:1 block on exercise

MODE SWITCH: DDD mode switches to DDI mode following atrial tachyarrhythmia to prevent tracking of this tachyarrhythmia

VENTRICULAR SAFETY PACING: **following A-Pace →** early ventricular pacing (AV delay: 100 ms) in the presence of a ventricular event detected inside the cross-talk detection window (preventing asystole in the presence of cross-talk or preventing R on T in the presence of a PVC)

POST-PVC EXTENSION OF PVARP: extension to 400 ms; prevents detection of a post-PVC retrograde P wave and therefore **the development of PMT**

RATE SMOOTHING: prevents an abrupt change of HR (during paroxysmal sinus arrest or following a mode switch)

RATE DROP RESPONSE: pacing at a higher rate (100-120 bpm) following an abrupt drop in HR (due to neurocardiogenic syncope)

NOISE RESPONSE: VOO or DOO mode activated following noise (nonphysiological signals)

PACEMAKER MONITORING

Battery	• ↘ Voltage and ↗ Impedance with time • **ERI**: Elective replacement indicator (< 3 months)
Lead	• **Impedance**: significant change > 200 ohms • **Low impedance (< 250 Ohms)**: insulation defect • **Increased impedance (> 1000 Ohms)**: short circuit (lead fracture; loose set screw) • Chest x-ray PRN
Events	• % A-Pace; % V-Pace; Frequency histogram • Saved episodes; AT/AF; Mode switch; Ventricular high rate; PMT
Sensitivity	• **Atrial**: from 0.3 to 0.6 mV • **Ventricular**: from 2 to 3.5 mV
Pacing	• **Safety margin**: programmed amplitude → twice the pacing threshold (or automatic capture) • **Pulse width**: 0.4 to 0.5 ms

MINIMUM FOLLOW–UP FREQUENCY FOR PPM, CRT, OR ICD	
Post-implantation follow-up	• < 72 h post-implant (in person) • 2 to 12 weeks post-implant (in person)
PPM or CRT follow-up	• 3 to 12 months (in person or by remote monitoring) • At least once a year in person
ICD follow-up	• 3 to 6 months (in person or by remote monitoring) • At least once a year in person
Signs of battery depletion	• Every 1 to 3 months (in person or by remote monitoring)

PACEMAKER DYSFUNCTION

Capture failure	• **Early post-implant:** lead migration; myocardial perforation; maturation (inflammatory reaction) • **Late lead maturation:** exit block • **Modified threshold:** myocardial infarction; cardiomyopathy; acidosis; electrolyte disorders; drugs (class IC AAD; Sotalol) • **Ineffective autocapture algorithm** • **Inadequate programming:** insufficient pacing amplitude safety margin • **Lead:** insulation defect; lead fracture; loose set screw • **Battery depletion** • **Failure to capture:** pacing during the refractory period; ± associated undersensing
Output failure	• **Oversensing** (inhibition) • **Lead:** insulation defect; short circuit (lead fracture; loose set screw) • **Hysteresis** • **Battery depletion** • **Post-PVC extension of PVARP** • **Generator dysfunction** (rare)
Undersensing	• **Inadequate intrinsic signal:** PVC or APC • **Signal modification:** myocardial infarction; cardiomyopathy; conduction disorder; metabolic disorder • **Programming:** high sensitivity • **Lead:** migration; maturation; insulation defect; lead fracture; loose set screw • **Magnet** • **Noise response** • **Safety pacing function** • **Battery depletion** • **Pseudofusion** • **Functional undersensing** (refractory period)
Oversensing	• **Cross-talk:** pacing of one chamber induces sensing of an event in the other chamber; minimized by blanking • **Far-field:** QRS detected as atrial event • **Oversensing of T wave** • **Electromagnetic interference:** electrocautery; MRI • **Myopotentials (unipolar electrode)** • **Lead:** insulation defect (internal contact of the two conductors); short circuit (lead fracture; loose set screw)

Pacing at a rate different from programmed rate	**High heart rate** • **Rate-adaptive:** R • **Undersensing** • **Tracking** of intrinsic atrial rhythm (or atrial oversensing) • **Rate smoothing** • **Rate drop** • **Pacemaker-mediated tachycardia** • **Runaway pacemaker** (battery depletion)	**Low heart rate** • **Oversensing** • **Hysteresis** • **AAI ⟷ DDD** • **Sleep mode** • **Battery depletion**

PACEMAKER-MEDIATED TACHYCARDIA (PMT)

- **Risk factors**: **A)** PVC with retrograde conduction; **B)** Atrial capture failure; **C)** Very long programmed AV delay; **D)** Atrial oversensing or undersensing
- **Mechanism**: Retrograde V-A conduction (often post-PVC) → A-Sense (outside of the PVARP) → V-Pace → retrograde V-A conduction → A-Sense (and so on)
- **Diagnosis**: **A)** A-Sense / V-Pace at the maximum pacing rate; **B)** A-Sense following V-Pace with V-A interval < 400 ms; **C)** Discordance between pacing rate and activity sensor; **D)** Modulation of P-V period
- **Prevention / Termination**: **A)** PVARP > retrograde V-A conduction time (while avoiding excessively prolonged TARP, which would lead to low frequency 2:1 block); **B)** Extension of post-PVC PVARP; **C)** 1 cycle without V-Pace following A-Sense during PMT

PACEMAKER SYNDROME: **secondary to loss of AV synchrony** (± atrial contraction on closed AV valve) with VVI pacemaker; tiredness / retrosternal chest pain / dyspnea / cough / confusion / faintness / syncope

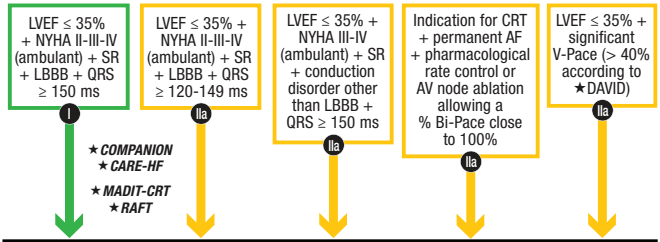
DIAPHRAGMATIC STIMULATION: lead close to phrenic nerve; incorrectly positioned lead (cardiac vein; myocardium perforation; migration); high stimulation amplitude

6.11/ CARDIAC RESYNCHRONIZATION THERAPY (CRT)

HEART FAILURE: altered electromechanical coupling → inter- and intraventricular delays → ventricular asynchrony → ↗ systolic dysfunction → altered myocardial metabolism / functional MR / ventricular remodeling / LV dilatation

SCIENTIFIC EVIDENCE	
• ★ **COMPANION**: LVEF ≤ 35% + NYHA III or IV (ambulant) + SR + QRS ≥ 120 ms + Hospitalization for heart failure during the previous year • ★ **CARE-HF**: LVEF ≤ 35% + NYHA III or IV (ambulant) + SR + QRS ≥ 150 ms (120-149 ms with TTE criteria of asynchrony)	• ★ **MADIT-CRT**: LVEF ≤ 30% + NYHA I (15%) or NYHA II (85%) + SR + QRS ≥ 130 ms • ★ **RAFT**: LVEF ≤ 30% + NYHA II (80%) or NYHA III (20%) + QRS ≥ 130 ms
• ↘ All-cause mortality • ↘ Hospitalization • Improvement of quality of life • Reverse remodeling	• ↘ All-cause mortality (★ RAFT) • ↘ Hospitalization • Improvement of quality of life • Reverse remodeling
MAINLY BENEFICIAL IN LBBB WITH QRS ≥ 150 MSEC	

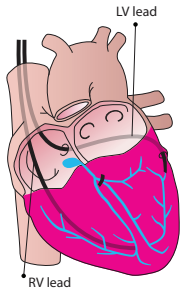
INDICATIONS



*Life expectancy with satisfactory functional capacity > 1 year

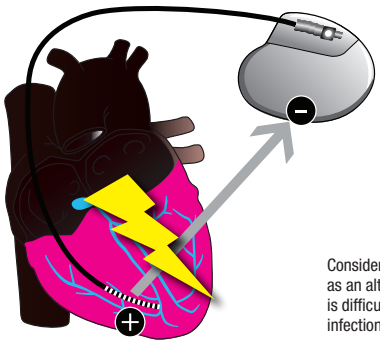
PROGRAMMING

RA pacing	• **Minimal** to avoid interatrial asynchrony • Minimum rate: 50 bpm • Do not activate "R"
AV delay	• **100-120 ms (minimize intrinsic AV conduction; ensure adequate duration of atrial kick)** • Consider echocardiography-guided optimization in the presence of a pseudonormal (grade II) or restrictive (grade III) mitral diastolic pattern
LV lead position	• **Basal posterolateral wall** (site of maximum electromechanical delay) • Avoid scars whenever possible (LGE on MRI); target adequate threshold; avoid phrenic nerve stimulation (electronic reprogramming of vectorial stimulation configuration PRN)
V-V delay	• **Simultaneous or pre-excitation of LV stimulation (30 ms)** • Echocardiographic optimization PRN in non-responders (using aortic VTI and/or deformation imaging and/or RV - LV pre-ejection intervals)
Maximize Bi-Pace	• **Target Bi-Pace > 98%** • AF → AV node blocking agent or RF ablation of AV node • Frequent PVCs → AAD or RF ablation
ECG	• **V1: dominant R wave** • **I: negative** • V4-V5: positive in the case of basal LV stimulation (negative if apical) • Frontal axis: -90° to 180°



V1	I	FRONTAL AXIS
RV apical stimulation		0 to -90°
Resynchronization therapy		-90 to 180°

6.12/ IMPLANTABLE CARDIOVERTER-DEFIBRILLATOR (ICD)



Consider **subcutaneous defibrillator** as an alternative when venous access is difficult; after removal of an ICD for infection; in young patients

SCIENTIFIC EVIDENCE

SECONDARY PREVENTION: ★ AVID; ★ CIDS; ★ CASH

› Reduction of the absolute mortality (vs Amiodarone): 10.5% at 36 months **(NNT 10 patients)** +

PRIMARY PREVENTION: reduction of absolute mortality of 5-8% at 36 months **(NNT 14-18 patients)** +

› ★ **MADIT-I**: Ischemic heart disease; LVEF ≤ 35%; NYHA I-II-III, NSVT; inducible VT → ↘ all-cause mortality

› ★ **MUSTT**: Ischemic heart disease; LVEF ≤ 40%; NYHA I-II-III, NSVT; inducible VT → ↘ all-cause mortality

› ★ **MADIT-II**: Ischemic heart disease; LVEF ≤ 30%; NYHA I-II-III → ↘ all-cause mortality

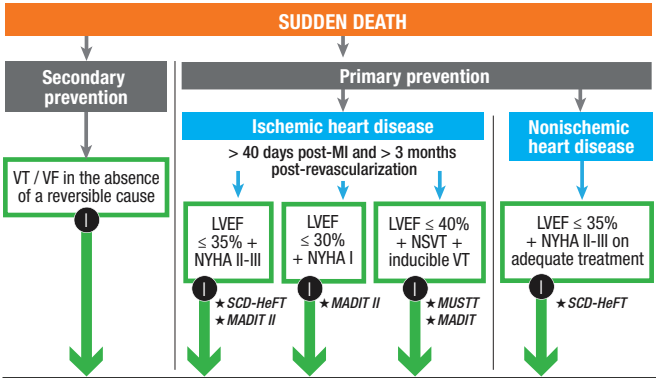
› ★ **DEFINITE**: Nonischemic heart disease; LVEF ≤ 35%; NYHA I-II-III, NSVT (or ≥ 10 PVCs / h) → trend to ↘ all-cause mortality

› ★ **SCD-HeFT**: LVEF ≤ 35%; (ischemic or nonischemic heart disease); NYHA II-III → ↘ all-cause mortality

› ★ **DINAMIT**: LVEF ≤ 35%; **< 40 days post-MI**; decreased HR variability or high resting HR → no benefit

› ★ **IRIS**: LVEF < 40%; **< 30 days post-MI**; HR > 90 bpm or NSVT > 150 bpm → no benefit

INDICATIONS



OTHER CONDITIONS HCM + risk factors • ARVD + risk factors • Long QT syndrome with syncope or VT on beta-blockers • Brugada with syncope or VT • Catecholaminergic polymorphic VT with syncope or VT on beta-blockers • Sarcoidosis or giant cell myocarditis or Chagas • LV noncompaction • Congenital heart disease

PROGRAMMING – PRIMARY PREVENTION

ZONE #1: SLOW VT	ZONE #2: FAST VT	ZONE #3: VF
150 to 188-200 bpm (400 to 320-300 ms)	**188-200 to 250 bpm (320-300 to 240 ms)**	**> 250 bpm (< 240 ms)**
• Monitor (at user discretion)	**a)** ≥ 1 ATP (**burst**) attempt (8 impulses at 84-88% of tachycardia CL) **b)** Maximum energy shock	• Maximum energy shock (> 30 J) x 6 (ATP during charge)

- **Detection duration**: ≥ 30 intervals (≥ 6-12 sec)
- **VT/VF discriminators vs supraventricular arrhythmia (up to 230 bpm)**: **A)** V > A / A-V dissociation; **B)** EGM morphology (vs baseline template); **C)** Abrupt onset; **D)** Stable R-R interval

ANTI-TACHYCARDIA PACING (ATP): interrupt the reentry circuit of monomorphic VT; effective in 70-80% of patients with fast VT (★ PainFREE Rx II)

- **Burst**: 8 impulses with constant inter-stimulus interval (at 88% of tachycardia CL)
- **Ramp**: 8 impulses with decreasing inter-stimulus interval

★ **MADIT-RIT:** primary prevention; administration of therapy only during fast VT (≥ 200 bpm) or following a period of prolonged detection (> 60 s for 170-199 bpm or > 12 s for 200-249 bpm or > 2.5 s for 250 bpm) associated with **↘ all-cause mortality / ↘ inappropriate ICD therapies**

PROGRAMMING – SECONDARY PREVENTION

DETECTION DURATION: ≥ 30 intervals (≥ 6-12 sec)

SLOWEST ZONE: at least 10 bpm below the documented tachycardia rate (but not faster than 200 bpm except for some young patients) → ATP (≥ 1 burst attempt - 8 impulses at 88% of VT CL; 10 ms scan decrement) → Shock

VF: > 250 bpm → ATP while charging → Shock (full output)

MANAGEMENT FOLLOWING AN ICD SHOCK

MEDICAL ASSESSMENT: < 24 h (urgent if multiple shocks or symptoms)

APPROPRIATE SHOCK: VF; monomorphic VT; polymorphic VT

INAPPROPRIATE SHOCK: apply a magnet over the device; reprogram treatment / parameters

- **Supraventricular tachycardia** → modify therapy zones; optimize discriminator programming; AV node blocking agent / AAD; RF ablation
- **T wave oversensing (and small R wave)** → decrease ventricular sensitivity (however, must be sufficient to detect VF; defibrillator test PRN); prolong the ventricular refractory period; modify sensing decay; lead repositioning
- **Atrial far-field** (distal coil of an integrated bipolar electrode close to the tricuspid valve)
- **R-wave double counting** → modify sensing decay; prolong the refractory period; decrease ventricular sensitivity (however, must be sufficient to detect VF; defibrillator test PRN)
- **Electromagnetic interference**
- **Myopotentials**
- **Lead** (insulation defect; lead fracture; loose set screw)

ELECTRICAL STORM: ▶▶| Ventricular fibrillation

PREVENTION OF NEW SHOCKS: BB; Amiodarone; Sotalol; therapy reprogramming; RF ablation

SHOCK APPROPRIATE BUT INEFFECTIVE

- **Increased defibrillation threshold**: ischemia; progressive heart failure; AAD (sodium channel blocking agents; Amiodarone); electrolyte / metabolic disorders; pleural / pericardial effusion
- **Secondary to defibrillator**: insufficient programmed shock amplitude; battery depletion; lead (insulation defect; lead fracture; loose set screw; migration)

7.1/ SEGMENTAL ASSESSMENT & FETAL CIRCULATION

SEGMENTAL ASSESSMENT

POSITION OF THE APEX: A) Levocardia (apex points to the left); **B) Dextrocardia** (apex points to the right); **C) Mesocardia** (apex in the middle)

ATRIAL SITUS (solitus; inversus; ambiguus): according to the position of the atrial appendages, IVC (which drains into the RA) and visceral situs

- **Right atrial appendage morphology:** large base, triangular shape, contains numerous pectinate muscles
- **Left atrial appendage morphology:** narrow base, finger-shaped

AV CONNECTION: A) Concordance: morphological LA connected to morphological LV (and RA connected to RV); **B)** Discordance

- **Right ventricle morphology:** moderator band, extensive trabeculations, infundibulum, tricuspid valve
  - **Tricuspid valve**: 3 leaflets - septal attachments - closer to apex than M valve - absence of distinct papillary muscles
- **Left ventricle morphology**: fine trabeculations; mitral valve
  - **Mitral valve:** 2 leaflets - mitro-aortic continuity - 2 papillary muscles - less apical than the T valve

VENTRICULO-ARTERIAL CONNECTION: A) Concordance: Morphological LV connected to the aorta; morphological RV connected to the PA; **B) Discordance**; **C) Double-outlet** (> 50% of the aorta and PA arise from the same ventricle)

- **Aorta:** "Candy cane"; 3 vessels (innominate artery, left carotid artery, left subclavian artery); always associated with its aortic valve
- **Pulmonary trunk**: rapidly divides into RPA and LPA; always associated with its pulmonary valve

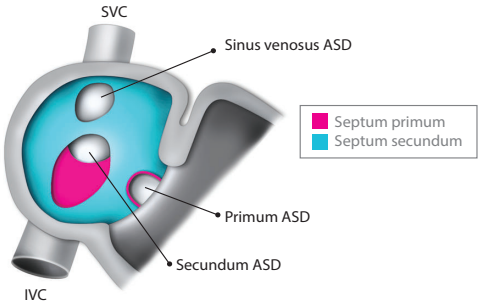
FETAL CIRCULATION

1. **DUCTUS VENOSUS:** allows oxygenated umbilical blood to short-circuit the liver and reach the IVC
2. **FORAMEN OVALE**: allows blood derived from the IVC (part of which is derived from the placenta and is oxygenated) to go directly to the left heart (preferentially perfusing the coronary arteries and CNS)
3. **PATENT DUCTUS ARTERIOSUS**: allows blood (predominantly derived from the SVC) to go from the right heart to the descending aorta (to the placenta)

7.2/ ATRIAL SEPTAL DEFECT (ASD)

4 TYPES

1. **SECUNDUM ASD (80 %):** in the fossa ovale
2. **PRIMUM ASD (15 %):** close to AV valves; associated with AV canal defect
3. **SINUS VENOSUS ASD (5 %):** close to the origin of the SVC (exceptionally IVC); associated with anomalous pulmonary venous connection (R > L)
4. **CORONARY SINUS ASD (1 %):** communication between the coronary sinus and the LA; associated with persistent left SVC



SIGNIFICANT ASD: generally **> 10 mm with Qp/Qs > 1.5: 1**

ACCENTUATION OF L → R SHUNT: in the presence of ↘ LV compliance or ↗ LA pressure (age; LVH; HTN; cardiomyopathy; myocardial infarction; MR...)

LUTEMBACHER SYNDROME: ASD + rheumatic MS

HOLT-ORAM SYNDROME: autosomal dominant; TBX5 mutation; abnormalities of hands; secundum ASD

FEATURES: left parasternal heave; palpable dilated PA (2nd left intercostal space); **fixed split S2**; pulmonary ejection murmur (↗ flow); tricuspid diastolic rumble in the presence of significant shunt; TR murmur in the presence of right heart failure

ECG

- **Secundum ASD: Incomplete RBBB; right axis deviation; RAH; Notch on R wave in inferior leads**
- **Primum ASD: RBBB; left axis deviation; RAH**
- **Sinus venosus ASD: non-sinus rhythm (negative P wave in inferior leads)**

CXR: RA-RV dilatation; ↗ vascularization; prominent central PA

TEE: evaluate pulmonary venous return; ASD dimensions; possibility of percutaneous closure; agitated-saline PRN (R→L shunt = contrast in left chambers; L→R shunt = negative contrast in right chambers)

COMPLICATIONS

a) Right heart failure (± TR) (volume overload)

b) Atrial arrhythmias: typical flutter; IART; AF; SSS after repair

c) Paradoxical embolism

d) PHT (5-9%) (rarely severe)

INDICATIONS FOR ASD CLOSURE

a) Dilatation of right chambers (I;B)

b) Paradoxical embolism (IIa;C)

c) Platypnea-orthodeoxia (IIa;C)

d) PHT with marked L→R shunt > 1.5: 1 or with significant reactivity to vasodilator (IIb;C)

e) Do not close if **irreversible PHT** with sPAP > 2/3 SBP or PVR > 2/3 SVR (III;C)

PERCUTANEOUS CLOSURE: possible if **secundum ASD < 38 mm with adequate margins (distance > 5 mm** from AV valves, coronary sinus, origin of SVC / IVC and right pulmonary veins) **and with normal pulmonary venous return**

› ASA for 6 months after ASD closure; **complications** (1 %) → prosthesis embolization; erosion (atrial wall or Ao); thromboembolism; arrhythmia - AF; endocarditis; tamponade

PACEMAKER LEADS: risk of paradoxical embolism if ASD not repaired

PREGNANCY: generally well tolerated; risk of paradoxical embolism

7.3/ PATENT FORAMEN OVALE (PFO)

Absence of fusion of septum secundum and septum primum at birth

25% of adults

ASSOCIATION WITH CRYPTOGENIC STROKE: possibility of paradoxical embolism

› **Risk factors**: PFO > 5 mm or spontaneous R→L shunt or atrial septal aneurysm or prominent Eustachian valve

DIAGNOSIS: TEE with bubbles: **bubbles in ≤ 3 beats in left chambers**; facilitated by Valsalva maneuver

TREATMENT OF CRYPTOGENIC STROKE: highly controversial

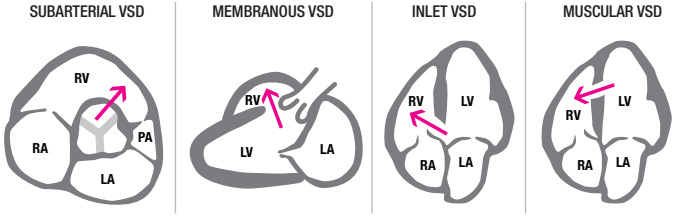
1) First-line ASA; Warfarin if documented DVT (± closure of PFO)
2) If recurrence: anticoagulation vs percutaneous closure
   - No convincing evidence for the superiority of percutaneous closure versus medical treatment (equivocal results in ★ CLOSURE-I, ★ RESPECT and ★ PC)

ANEURYSM OF INTERATRIAL SEPTUM: **redundant and mobile portion of the atrial septum with excursion ≥ 15 mm** from the midline

7.4/ VENTRICULAR SEPTAL DEFECT (VSD)

4 TYPES

1) **SUBARTERIAL** (5%): below the Ao and P valves; associated with AR (due to leaflet prolapse); numerous synonyms (outlet; conal; subpulmonary; subaortic; infundibular; supracristal)
2) **MEMBRANOUS** (80%): membranous septum; adjacent to Ao and T valves
3) **AV CANAL (INLET)**: below the AV valve (see AV canal defect)
4) **MUSCULAR** (15-20%): completely surrounded by muscle



CLINICAL FEATURES AND SEVERITY: **Restrictive VSD** (RV pressure << LV pressure) or **nonrestrictive VSD** (RV pressure similar to LV pressure)

- **Small VSD**: normal LV dimensions; absence of PHT; **holosystolic murmur in left parasternal region (3rd-4th left intercostal spaces) with spoke-wheel radiation ± palpable thrill**; spontaneous closure is possible
- **Moderate VSD**: **LA and LV dilatation (volume overload)**; PHT (reversible); ± mitral diastolic rumble; S3; lateralized apex
- **Large VSD**: Progressive PHT then Eisenmenger; **absence of VSD murmur; signs of PHT (left parasternal heave; ↗ and palpable P2; right S4; ejection click; Graham-Steel murmur and TR)**

COMPLICATIONS

a) Left heart failure (volume overload)

b) PHT (± right heart failure due to pressure overload)

c) Progressive AR due to leaflet prolapse (subarterial VSD or membranous VSD)

d) Double chamber RV (muscle band develops as a result of the VSD jet, inducing subpulmonary stenosis)

e) Progressive subaortic stenosis

f) Arrhythmia: AF; PVCs; NSVT; postoperative AV block

g) Endocarditis

INDICATIONS FOR VSD CLOSURE

a) Significant VSD: symptoms or progressive left ventricular dysfunction (volume overload) or right ventricular dysfunction (pressure overload) or Qp:Qs > 2:1 or sPAP > 50 mmHg (I;B)

b) Subarterial or membranous VSD with **AR ≥ moderate** (I;B)

c) In the presence of **severe PHT** (sPAP > 2/3 SBP or PVR > 2/3 SVR), closure should only be considered in the case of L→R shunt > 1.5:1 or significant reactivity to vasodilators (I;B)

d) **Double chamber RV**: significant obstruction (mean gradient > 40 mmHg or > 30 mmHg with symptoms)

e) Endocarditis (IIa;B)

PERCUTANEOUS CLOSURE IS POSSIBLE: **A)** Trabecular muscle VSD situated away from T or Ao valves; **B)** Membranous VSD situated away from the Ao valve

PREGNANCY: a small VSD is well tolerated in the absence of associated PHT or LV dysfunction

7.5/ ATRIOVENTRICULAR CANAL DEFECT

Developmental anomaly of endocardial cushions

a) **Partial atrioventricular canal defect:** intact interventricular septum; primum ASD; mitral cleft; AV valves inserted at same level (common annulus)

b) **Complete atrioventricular canal defect:** defect of the septum on either side of the cardiac crux: non-restrictive VSD (inlet VSD) and primum ASD; common atrioventricular orifice (one common AV valve with 5 leaflets)

- **Associated Down syndrome** (Trisomy 21): small stature, typical facies, mental retardation, brachydactyly, atlanto-axial instability, hypothyroidism, propensity to PHT, OSAHS

ECG: Complete or incomplete RBBB; **left axis deviation; spontaneous or postoperative AV block;** atrial arrhythmia +

VENTRICULOGRAPHY: **Elongated LVOT (goose neck deformity)**

COMPLICATIONS

a) **Left and right AV valve regurgitation**
b) **Left heart failure** (secondary to VSD and left AV valve regurgitation)
c) **Right heart failure** (secondary to ASD and right AV valve regurgitation)
d) PHT; Eisenmenger if not operated
e) **Arrhythmias: AF; flutter; AV block**
f) Progressive subaortic stenosis
g) Paradoxical embolism
h) Postoperative residual shunt
i) Postoperative mitral stenosis

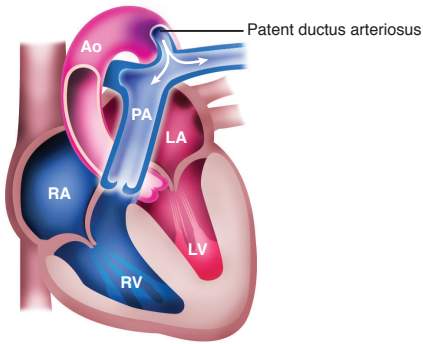
INDICATIONS FOR SURGERY

Patient already operated

a) **Hemodynamically significant** persistent or *de novo* defect (I;B)
b) **Deterioration of LV function** (I;B)
c) **Symptomatic left AV valve regurgitation** (I;B)
d) **Symptomatic left AV valve stenosis** (post-repair) (I;B)
e) **Subaortic obstruction** with mean gradient > 50 mmHg (I;B)
f) Do not operate if **severe, irreversible PHT** (sPAP > 2/3 SBP or PVR > 2/3 SVR) (III;C)

7.6/ PATENT DUCTUS ARTERIOSUS

Connection between proximal pulmonary artery and descending aorta (distal to the left subclavian artery)



A) SILENT DUCTUS ARTERIOSUS: incidental finding on TTE

B) SMALL PATENT DUCTUS ARTERIOSUS: continuous murmur; minimal hemodynamic impact; Qp/Qs < 1.5:1

C) MODERATE PATENT DUCTUS ARTERIOSUS: **continuous machinery murmur in 2nd left intercostal space ± thrill; increased pulse pressure**; bounding pulse; LV dilatation (lateralized, hyperdynamic apex); S3; reversible PHT (induces ↘ duration of the murmur)

D) LARGE PATENT DUCTUS ARTERIOSUS: Severe PHT; Eisenmenger physiology; absence of continuous murmur; **differential hypoxemia and cyanosis (lower limbs cyanosed; clubbing of the toes)**

TTE: flow from aorta to PA visible on PLAX (RVOT/PA view); **diastolic flow reversal** in descending aorta

COMPLICATIONS

a) **Left heart failure (volume overload)**
b) Progressive PHT
c) Arrhythmias (AF)
d) Endarteritis / Ductus aneurysm

INDICATIONS FOR SURGERY

a) **All cases of patent ductus arteriosus** except when silent or large with irreversible PHT (IIa;B)
b) **Endarteritis** (IIa;B)
c) In the presence of **severe PHT** (sPAP > 2/3 SBP or PVR > 2/3 SVR), closure should only be considered in the case of L→R shunt > 1.5:1 or significant reactivity to vasodilators (IIa;B)

PERCUTANEOUS CLOSURE: preferable in the case of ductus arteriosus < 8 mm (without aneurysm) or in the presence of calcification

PREGNANCY: similar considerations to those of VSD

7.7/ LEFT VENTRICULAR OUTFLOW TRACT OBSTRUCTION

SUPRAVALVULAR AORTIC STENOSIS

Fixed obstruction above the sinus of Valsalva

CORONARY ARTERIES submitted to high pressures; risk of dilatation / ostial stenosis / early CAD; requires regular screening for CAD

WILLIAMS SYNDROME: autosomal dominant; 7q11.23 deletion; supravalvular aortic stenosis, peripheral pulmonary artery stenosis, renal artery stenosis, HTN, hypercalcemia, cognitive deficits, "cocktail" personality, elf-like facies

CLINICAL FEATURES: **BP right arm >> BP left arm (Coanda effect with preferential jet to innominate artery)**; crescendo-decrescendo systolic murmur; suprasternal thrill; **increased A2**; absence of ejection click; S4; peripheral PA stenosis can cause end-systolic or continuous posterior murmur

VENTRICULOGRAPHY: **"ballerina foot" pattern of LV**

INDICATIONS FOR SURGERY (patch aortoplasty or ascending aorta replacement or resection with end-to-end anastomosis)

a) **Symptoms and/or mean gradient > 50 mmHg** (I;C)
b) **Doppler instantaneous maximum gradient > 70 mmHg** if mild obstruction (I;C)

VALVULAR AORTIC STENOSIS

BICUSPID AORTIC VALVE (▶▶| Chapter 4 - Valvular heart disease)

ASSOCIATED WITH: CoA; patent ductus arteriosus; ascending aortopathy

ROSS PROCEDURE: replace the aortic valve by the patient's pulmonary valve and replace the pulmonary valve by a cadaveric homologous graft; reimplantation of coronary arteries

› **Complications:** structural deterioration of the homologous P graft; aortopathy (specific to bicuspid aortic valve); AR; coronary stenosis

SUBVALVULAR AORTIC STENOSIS

Discrete membrane or tunnel-shaped LVOT stenosis

ASSOCIATED WITH: AR (valvular damage caused by the high velocity jet); VSD; AV canal defect; Shone complex

› **Shone complex**: multiple stenoses at different levels: **A)** Supravalvular mitral annulus or parachute mitral valve; **B)** Subvalvular aortic stenosis; **C)** Bicuspid aortic valve; **D)** CoA

DDX: HCM (absence of SAM in subaortic stenosis)

CLINICAL FEATURES: crescendo-decrescendo systolic murmur ± thrill; **no radiation to the carotids; absence of ejection click; AR diastolic murmur** +

INDICATIONS FOR SURGERY

a) **Symptoms with Doppler instantaneous maximum gradient > 50 mmHg** or mean gradient > 30 mmHg (I;C)
b) **Associated progressive AR** (I;C)

MEMBRANE: resection of the membrane ± myomectomy ± AVR

TUNNEL: Konno procedure (aortoventriculoplasty ± AVR)

› Complications: recurrence; AV block; iatrogenic VSD

7.8/ COARCTATION OF THE AORTA (COA)

Stenosis in the region of the ligamentum arteriosum (distal to the left subclavian artery)

ASSOCIATED ABNORMALITIES: Bicuspid aortic valve (80% of cases); aneurysm of the circle of Willis; collateral circulation (intercostal and mammary arteries); aortopathy; anomalous brachiocephalic circulation; aortic arch hypoplasia; VSD; Shone complex

› **Turner Syndrome** (45, X): CoA (35%); bicuspid aortic valve; ASD; VSD

SIGNIFICANT COA (IN THE ABSENCE OF COLLATERAL): **HTN in arms with trans-CoA gradient on catheterization > 20 mmHg or with SBP in arms ≥ 20 mmHg higher than SBP in legs** +

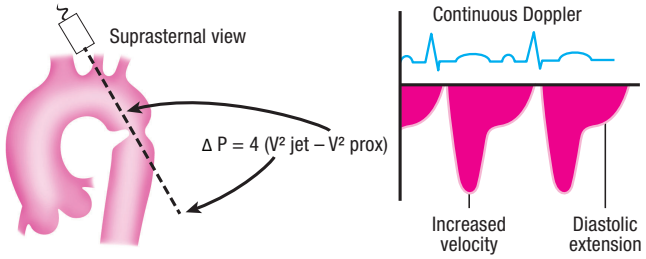
CLINICAL FEATURES

› **In the absence of collaterals**: **HTN in arms; SBP in arms higher than in legs; radiofemoral delay on palpation of pulse; interscapular ejection murmur (rarely continuous); S4; ↗ A2**; systolic click / systolic murmur in the presence of bicuspid aortic valve
› **In the presence of collaterals**: continuous crescendo-decrescendo murmur in left parasternal region or left scapula

CXR: **A) "3" sign:** indentation of the aorta at the site of CoA with distal and proximal dilatation; **B) Erosion of the ribs:** intercostal collaterals +

TTE: turbulence and ↗ velocity in descending Ao (suprasternal view) with diastolic extension of anterograde flow

› **Abdominal aorta:** ↘ velocity of systolic flow and diastolic extension of anterograde flow



MANAGEMENT

a) Congenital cardiology follow-up for life
b) Control of BP (at rest and on exercise) and cardiovascular risk factors
c) BB if aortopathy
d) Imaging of the entire aorta (MRI) with regular follow-up (by TTE for ascending Ao / Ao valve and MRI for entire Ao)
e) Brain MRI (rule out aneurysm of the circle of Willis)
f) Avoid contact sports / isometric exercises if residual CoA or associated aortopathy

COMPLICATIONS

a) **Left heart failure (pressure overload)**
b) Persistent HTN
c) Aortopathy / Aortic dissection
d) Aortic valve disease
e) Early CAD and PAD
f) Intracranial aneurysms / Hemorrhage
g) Endarteritis

INDICATIONS FOR SURGERY

› **In the presence of significant CoA: peak-to-peak gradient ≥ 20 mmHg** on catheterization or less in the presence of collaterals (I;C)

PERCUTANEOUS APPROACH (dilatation + stenting): preferable in the majority of cases (except in the case of a long or tortuous lesion) and preferred technique in the presence of re-coarctation

› **Complications:** aortic dissection / rupture; stroke; aneurysm or pseudoaneurysm; aortobronchial fistula; re-CoA; persistent HTN

SURGICAL OPTIONS: resection with end-to-end anastomosis or graft placement; patch aortoplasty; subclavian flap aortoplasty; bypass graft

› **Complications**: paraplegia; recurrent laryngeal nerve or phrenic nerve paralysis; dissection; aneurysm (post-patch aortoplasty); pseudoaneurysm; claudication of arms (subclavian flap aortoplasty); re-CoA; persistent HTN; endarteritis

POST-REPAIR FOLLOW-UP: Regular MRI and regular TTE

› Consider screening for intracranial aneurysms in the circle of Willis

PREGNANCY: pregnancy contraindicated if CoA not repaired (risk of IUGR - fetal loss - HTN); imaging of the entire Ao is necessary

7.9/ RIGHT VENTRICULAR OUTFLOW TRACT OBSTRUCTION

SEVERITY

	MILD	MODERATE	SEVERE
Doppler instantaneous maximum gradient (mmHg)	< 36	36 - 64	**> 64**
Peak velocity (m/s)	< 3	3 - 4	**> 4**

* Doppler measurements not valid in the presence of long stenosis / tunnel stenosis

SUPRAVALVULAR PULMONARY STENOSIS / PERIPHERAL PULMONARY ARTERY STENOSIS

ASSOCIATED WITH: TOF; Williams syndrome; Noonan syndrome; Alagille syndrome; VSD; Congenital rubella

CLINICAL FEATURES: systolic ejection murmur (left parasternal region and posterior; increased by inspiration; sometimes continuous in peripheral pulmonary artery stenosis); absence of ejection click; increased or preserved P2; left parasternal heave

SUBVALVULAR PULMONARY STENOSIS

Associated with VSD or TOF

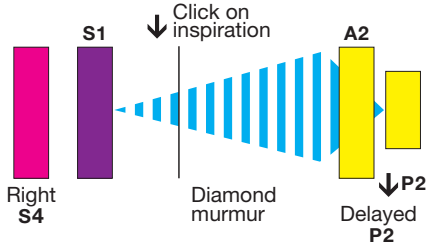
DOUBLE CHAMBER RV: mid-chamber obstruction secondary to a prominent muscle band; associated with VSD

VALVULAR PULMONARY STENOSIS

2 TYPES

1) **Dome-shaped**: thin, pliable, mobile valve; fusion of commissures; post-stenotic dilatation of the PA
2) **Dysplastic (10-15%)**: thickened, immobile leaflets; associated with Noonan syndrome; absence of post-stenotic dilatation

CLINICAL FEATURES: Prominent a wave in jugular vein; left parasternal heave; crescendo-decrescendo systolic murmur ± thrill; **ejection click if the valve is pliable** (early if severe PS; absent in the presence of a dysplastic valve; ↘ **during inspiration** due to premature valve opening); delayed and decreased P2 (absent if severe PS); right S4; ± cyanosis (if ASD or PFO)



Noonan syndrome: autosomal dominant; dysplastic pulmonary valve, pulmonary artery stenosis, ASD, HCM, developmental delay, facial dysmorphism, small stature, congenital lymphedema

LEOPARD syndrome: autosomal dominant; lentigines, ECG abnormalities, ocular hypertelorism, pulmonary stenosis, abnormal genital organs, growth retardation, deafness, LVH

POSSIBLE COMPLICATIONS

- **RVH**
- Right heart failure ± TR
- Pulmonary regurgitation (postoperative)
- Pulmonary artery dilatation (post-stenotic)
- Cyanosis in the presence of associated ASD or VSD
- Atrial arrhythmia (AF / flutter) or ventricular arrhythmia

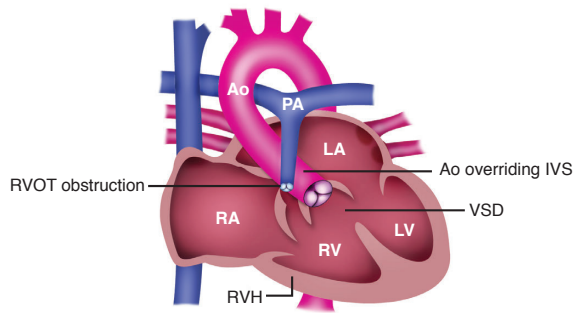
INDICATIONS FOR SURGERY

a) Balloon valvuloplasty for **dome-shaped valvular stenosis with symptoms and maximum Doppler gradient > 50 mmHg** or mean gradient > 30 mmHg (I;C)
b) Balloon valvuloplasty for **asymptomatic dome-shaped valvular stenosis and maximum Doppler gradient > 60 mmHg** or mean gradient > 40 mmHg (I;C)
c) **Surgery if significant RVOT obstruction with:** dysplastic valve or supravalvular stenosis or subvalvular stenosis or associated pulmonary hypoplasia or severe associated PR (I;C)
d) **Severe postoperative PR:** deterioration of functional class or deterioration of RV function or significant TR or flutter / AF or sustained ventricular arrhythmia (I;C)
e) **Valvular stenosis with**: significant arrhythmia or ASD / VSD (with R→L shunt) or recurrent endocarditis (IIa;C)
f) **Double chamber RV** with significant mid-chamber obstruction (gradient > 50 mmHg on catheterization) (IIa;C)

PREGNANCY: well tolerated if RV pressure < 70% of LV pressure; valvuloplasty as required during pregnancy in the presence of severe refractory symptoms (ideally after first trimester)

7.10/ TETRALOGY OF FALLOT (TOF)

COMBINATION OF: A) Non-restrictive (subarterial) VSD; **B)** RVOT obstruction (infundibular, valvular or supravalvular); **C)** RVH; **D)** Aorta overriding the septum



CORRECTIVE SURGERY: **A) Closure of the VSD; B) RVOT disobstruction**; **C)** ± infundibulectomy or subannular patch or transannular patch (induces significant PR) or RV - PA conduit (if congenital coronary artery anomalies crossing over the RVOT) or PVR or pulmonary valvotomy or pulmonary arterioplasty

ASSOCIATED ABNORMALITIES: right aortic arch; secundum ASD (pentalogy of Fallot); pulmonary trunk and peripheral pulmonary artery stenosis / hypoplasia; congenital coronary artery anomalies (LAD with ectopic origin crossing over the RVOT)

- **DiGeorge syndrome** (15% of TOF): 22q11 deletion; facial dysmorphism, hypocalcemia, thymus hypoplasia, immune deficit, psychiatric illness, truncus arteriosus, interrupted aortic arch, double outlet RV

CLINICAL FEATURES (POST-CORRECTION): left parasternal heave; soft ejection murmur (RVOT); subtle and soft diastolic pulmonary murmur (PR); ± absent P2; ± holosystolic murmur in the case of residual VSD; ± AR murmur

ECG: RBBB; wide QRS **(QRS > 180 ms is a risk factor for VT)** +

INVESTIGATIONS: **A)** TTE; **B)** MRI (RV and LV function and dimensions; PR; TR; RVOT; pulmonary arteries; shunt; Ao); **C)** Stress test (exercise capacity); **D)** Holter; **E)** Electrophysiological study PRN

TTE: Severe PR if **the continuous Doppler regurgitation envelope is dense and reaches zero before the end of diastole** (equalization of pressures on either side of the valve) or if PHT < 100 msec +

POST-CORRECTION COMPLICATIONS

- **Pulmonary regurgitation**
- **RV dysfunction / RV dilatation (± TR)**
- Residual RVOT obstruction (subvalvular, valvular or supravalvular) / peripheral pulmonary artery stenosis (causing RV pressure overload)
- Residual VSD
- Infundibular aneurysm
- LV dysfunction
- Aortic root dilatation / Progressive AR
- Arrhythmia: atrial flutter; IART; AF; AV block
- VT (RVOT heavily scarred from surgical intervention); sudden death (0.2% year)
- Endocarditis

INDICATIONS FOR POST-CORRECTION SURGERY (IIA;C)

a) **Severe PR** with: symptoms or moderate-to-severe RV dilatation (**end-diastolic volume > 170 mL/m²; end-systolic volume > 85 mL/m²**) or moderate-to-severe RV dysfunction (**RVEF < 45 %**) or moderate-to-severe TR or atrial or ventricular arrhythmia +
b) **Residual VSD** with shunt > 1.5:1
c) **Moderate to severe RVOT obstruction** (peak Doppler gradient > 50 mmHg)
d) **Severe AR** with symptoms or LV dysfunction
e) **Aortic root > 55 mm**
f) **RVOT aneurysm or false aneurysm**
g) **Combination** of residual VSD and/or residual PS and PR inducing RV dilatation / dysfunction or symptoms

SURGICAL OPTIONS: A) PVR (bioprosthesis or cadaver) ± tricuspid annuloplasty; **B)** Percutaneous pulmonary valve inserted into a pre-existing RV-PA conduit; **C)** Infundibular resection or RVOT patch or transannular patch or valved conduit if obstruction persists

VENTRICULAR ARRHYTHMIA: **Risk factors**: **A)** Inducible VT on EPS; **B)** QRS > 180 ms; **C)** History of palliative shunt; **D)** Significant PR or RVOT obstruction; **E)** Advanced age at the time of complete correction; **F)** NSVT on Holter; **G)** RV or LV dysfunction; **H)** Syncope; **I)** Severe RV dilatation (> 150-180 ml/m²)

- **Secondary prevention**: ICD indicated
- **Primary prevention**: indication for ICD determined on an individual basis according to the risk of sudden death (risk of frequent inappropriate shocks)

PREGNANCY: risk of right heart failure in the presence of RVOT obstruction and/or severe PR and/or RV dysfunction; screen for 22q11 deletion

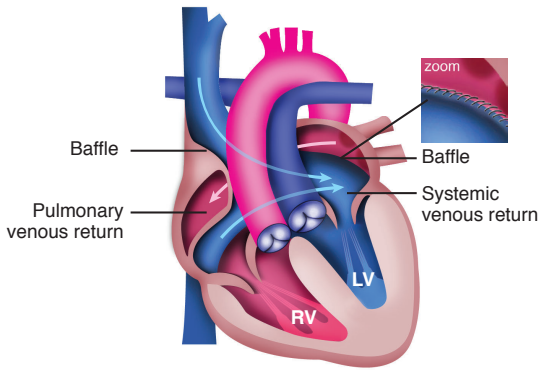
7.11/ TRANSPOSITION OF THE GREAT ARTERIES (D-TGV)

Atrioventricular concordance and ventriculoarterial discordance (the RA is connected to the morphological RV which is connected to the Ao; the LA is connected to the morphological LV which is connected to the PA); incompatible with life in the absence of operation (2 parallel circuits)

POSITION OF THE AORTA: anterior and to the right of the PA (connected to the RV)

ASSOCIATED ABNORMALITIES: VSD; LVOT obstruction; ASD; CoA; congenital coronary artery anomalies

ATRIAL SWITCH: MUSTARD (OR SENNING) PROCEDURE



The majority of adults have undergone this procedure (but this operation was replaced by arterial switch in about 1990); the blood is redirected to the atria by means of a conduit (baffle) made from pericardium or Dacron allowing physiological correction (systemic venous blood is redirected towards the subpulmonary LV; pulmonary venous blood is redirected towards the subaortic RV)

CLINICAL FEATURES: Single S2 (loud A2; P2 is inaudible as the PA is posterior); left parasternal heave; holosystolic murmur of the systemic AV valve

ECG: RVH; block - bradycardia; atrial arrhythmia

CXR: Egg-shaped heart (narrow mediastinum due to parallel great vessels); retrosternal aorta (lateral view)

TTE: Ao and PA are parallel; phasic flow in the baffle with **peak velocity < 1 m/s**; agitated-saline to evaluate baffle leak or stenosis

COMPLICATIONS

a) **Systemic RV failure (+ TR)**
b) Systemic RV ischemia (perfused only by the RCA)
c) Systemic AV valve regurgitation (abnormal septal geometry)
d) Obstruction of the baffle (SVC; IVC)
e) Baffle leak (paradoxical embolism; cyanosis)
f) Subpulmonary obstruction (abnormal LV geometry)
g) Arrhythmias: atrial flutter; IART; SSS; AV block
h) VT - Sudden death (risk factors: RV dysfunction; age; supraventricular arrhythmia; QRS > 140 ms)

INDICATIONS FOR POST-MUSTARD SURGERY (IIA;C)

a) **Moderate-to-severe systemic AV valve regurgitation**
b) **SVC or IVC obstruction** (dilatation + stent in baffle)
c) **Pulmonary vein obstruction** (post-Senning procedure)
d) **Baffle leak with:** significant shunt (Qp:Qs > 1.5:1) or symptoms or PHT or progressive ventricular dilatation / dysfunction or need for pacemaker transvenous lead or R→L shunt with cyanosis (percutaneous closure of the leak)
e) **Symptomatic tachyarrhythmia**: ablation
f) **Bradyarrhythmia:** pacemaker with endovenous lead in the absence of baffle stenosis or baffle leak
g) **Consider transplant** if severe systemic RV dysfunction

PREGNANCY: avoid pregnancy in the presence of moderate-to-severe systemic RV dysfunction and/or severe systemic AV valve regurgitation

ARTERIAL SWITCH: JATENE PROCEDURE

Switching of the Ao and PA; the PA is replaced anteriorly (Lecompte maneuver); the coronary arteries are reimplanted; the LV becomes subaortic

COMPLICATIONS

a) Obstruction of the aorta and pulmonary artery at the sites of surgical anastomosis
b) Subpulmonary or PA or pulmonary arterial branch obstruction following Lecompte maneuver
c) Aortic root dilatation / AR
d) Stenosis of the coronary ostia (regular screening for CAD is indicated)

INDICATIONS FOR POST-JATENE SURGERY (IIA;C)

a) Significant PA obstruction (subvalvular, supravalvular or arterial branch)
b) Coronary artery obstruction
c) Severe AR
d) Severe Ao dilatation > 55 mm

RASTELLI PROCEDURE

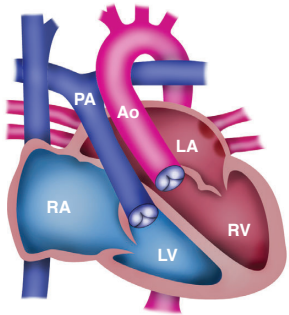
For treatment of D-TGV with VSD and RVOT obstruction

PROCEDURE: **A)** LVOT tunneled to the Ao by an intracardiac patch through the VSD; **B)** RV - PA extracardiac valved conduit

7.12/ CONGENITALLY CORRECTED TRANSPOSITION OF GREAT ARTERIES (L-TGV)

DOUBLE DISCORDANCE (atrioventricular and ventriculoarterial): the circulation is corrected physiologically; the morphological RV is systemic (subaortic)

POSITION OF THE AORTA: anterior and to left of the PA



ASSOCIATED ABNORMALITIES: abnormalities of the systemic T valve (Ebstein-like malformation); VSD; PS; dextrocardia

ECG: AV block (fragile His bundle wich is displaced anteriorly and laterally); septal activation from R to L (septal Q waves absent on left precordial leads, but present on right precordial and inferior leads); accessory pathway

CLINICAL FEATURES: Palpable A2 (anterior Ao); inaudible P2 (posterior PA); holosystolic murmur due to systemic AV valve regurgitation

COMPLICATIONS

a) **Progressive systemic AV valve regurgitation (T valve)**
b) **Progressive systemic RV dysfunction**
c) Systemic RV ischemia (only perfused by the RCA)
d) **Complete AV block (2% / year)**
e) **Atrial arrhythmia:** AF; IART; accessory pathway
f) VT - sudden death

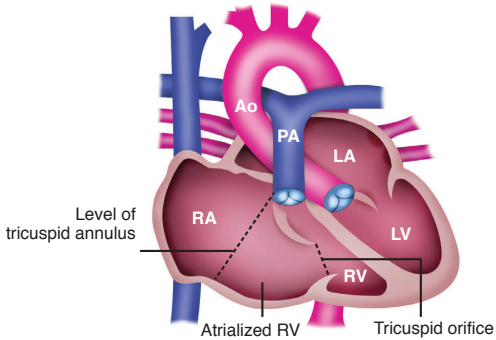
INDICATIONS FOR SURGERY

a) Moderate-to-severe systemic AV valve **regurgitation** (IIa;B)
b) **Deterioration of the systemic RV** (IIa;C): consider heart transplantation

PREGNANCY: avoid pregnancy if RVEF < 40% and/or moderate-to-severe TR

7.13/ EBSTEIN ANOMALY

Apical displacement of the tricuspid valve **> 8 mm/m²** (septal and posterior leaflets) with elongated / redundant anterior leaflet; atrialized RV (small volume functional RV)



ASSOCIATED ABNORMALITIES: A) Accessory pathway(s) (25% of patients; 50% have multiple pathways); **B)** secundum ASD or PFO ± cyanosis (50% of patients); **C)** RVOT obstruction (by T valve); VSD; mitral valve disease

CLINICAL FEATURES: ± V wave in jugular veins (often absent due to severe RA dilatation); left parasternal heave; split S1 with ↗ T1; split S2 (RBBB); right S3; lower left parasternal holosystolic murmur (↗ on inspiration); systolic clicks; ± cyanosis; low output state; signs of right heart failure

ECG: RA dilatation (Himalayan P waves); low voltage; ± pre-excitation; RBBB; Q waves in V1 (as far as V4) and inferior leads; AF - flutter

CXR: "water bottle heart": RA dilatation and left convexity (dilatation of the RV infundibulum); ↘ vascularization

COMPLICATIONS

a) **Severe TR**
b) **Right heart failure / Dilatation of right chambers**
c) Arrhythmias: flutter; AF; AT; accessory pathway(s)
d) Sudden death (pre-excited atrial arrhythmia or VT)
e) Cyanosis - paradoxical embolism in the presence of PFO or ASD
f) RVOT obstruction due to the abnormal tricuspid valve
g) Tricuspid stenosis or prosthetic valve dysfunction post-surgery

INDICATIONS FOR SURGERY (I;B)

a) **Severe TR** with NYHA III - IV or deterioration of functional class
b) **Progressive RV dysfunction or dilatation**
c) **Progressive cardiomegaly** on CXR (cardiothoracic ratio > 65%)
d) **Cyanosis** with resting SaO_2 < 90% (closure of ASD)
e) **Paradoxical embolism** (closure of ASD)
f) **Arrhythmia / WPW**: ablation by catheter or surgical cryoablation

REPAIR: feasibility according to: **A) Length and mobility of the anterior leaflet (creation of a monoleaflet valve); B) Size of the residual RV > 1/3 of total RV**

OTHER SURGICAL OPTIONS

- **Conventional TVR**
- **Bidirectional cavopulmonary connection** (**bidirectional Glenn**): decreases preload and workload of the small RV
- **Fontan procedure in** the presence of a hypoplastic RV
- **Heart transplantation**

PREGNANCY: well tolerated in the absence of cyanosis / right heart failure / arrhythmia

7.14/ MARFAN SYNDROME

Autosomal dominant; FBN1 gene mutation (> 1,000 mutations have been reported)

COMPLICATIONS: Aortic root dilatation; aortic dissection; AR; MVP - MR; left heart failure; tricuspid valve prolapse - TR

MANAGEMENT

a) BB (↘ dP/dT) and ARB
b) Target SBP < 120 mmHg (BB; ARB)
c) Avoid isometric exercise - competitive / contact sports
d) MRI indicated to evaluate all of the aorta; regular follow-up is recommended

TTE FOLLOW-UP	MRI OR CT ANGIOGRAPHY
Annually	Every 3 to 5 years (more frequent if dilatation / imminent indication for surgery / 1 year postop / recent dissection)

INDICATIONS FOR SURGERY (I;B)

a) **Ascending aorta > 50 mm**
b) **Ao > 45 mm**: with: progression > 5 mm/year or progressive AR with probable valve preservation or family history of aortic dissection with Ao < 50 mm or severe MR requiring surgery
c) **Ao > 40 mm before pregnancy**
d) **Other regions of the Ao** between 50-60 mm or progressive dilatation

SURGICAL OPTIONS: A) Bentall procedure: replacement of ascending Ao with valved graft; **B) David procedure:** replacement of the ascending Ao with graft and resuspension of the native aortic valve (valve sparing)

PREGNANCY: risk of transmission (autosomal dominant); MRI imaging of the entire Ao; TTE every 4-8 weeks; BB; avoid ↗ dP/dT during delivery; cesarean section if unstable aorta (> 40-45 mm)

- **Pregnancy contraindicated if Ao > 45 mm** (risk of aortic dissection)
- **If Ao ≥ 40 mm**: referral for sugery is recommended if contemplating pregnancy

GHENT CRITERIA

SYSTEM	MAJOR CLINICAL SIGNS	MINOR CLINICAL SIGNS	DEFINITION OF SYSTEM INVOLVEMENT
Skeletal	• *Pectus carinatum* • Surgical *Pectus excavatum* • Long limbs › Arm span to height ratio > 1.05 or › ↘ Upper segment to lower segment ratio • Long fingers › Wrist sign and thumb sign • Scoliosis > 20° or spondylolisthesis • Maximum elbow extension < 170° • Flat foot • Acetabular protrusion (hip x-ray)	• Moderate *Pectus excavatum* • Joint hypermobility • Arched palate with overlapping teeth • Characteristic facies	**Major** ≥ 4 major signs **Minor** ≥ 2 major signs or 1 major and 2 minor signs
Ocular	• Lens dislocation	• Flat cornea • Elongated eyeball • Myopia	**Major** 1 major sign **Minor** ≥ 2 minor signs
Cardio-vascular	• Aortic root dilatation • Aortic dissection	• MVP • Pulmonary trunk dilatation < 40 years • MAC < 40 years • Dilatation or dissection of the descending thoracic aorta or abdominal aorta < 50 years	**Major** ≥ 1 major sign **Minor** ≥ 1 minor sign
Pulmonary		• Spontaneous pneumothorax • Apical bulla (CXR or CT)	**Minor** ≥ 1 minor sign
Cutaneous		• *Striae atrophicae* (unexplained) • Recurrent incisional herniae	**Minor** ≥ 1 minor sign
Dura mater	• Lumbosacral dural ectasia (CT or MRI)		**Major** 1 major sign
Genetic	• 1 first-degree relative with diagnostic criteria • FBN1 gene mutation causing Marfan		

Diagnosis established:
- **1 system with major involvement + 1 system with minor involvement + 1 genetic criterion**
- **2 systems with major involvement + 1 system with minor involvement**

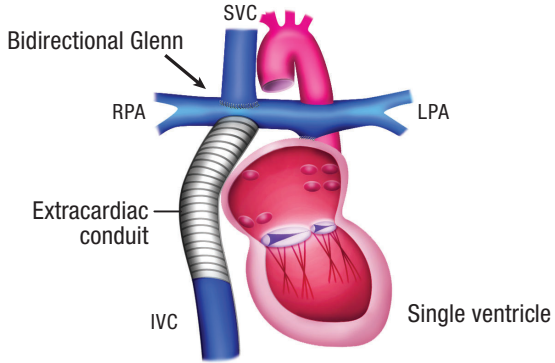
Lœys BL, Dietz HC, Braverman AC, et al. J Med Genet 2010; 47:476-485

7.15/ FONTAN PROCEDURE

Palliative procedure in the presence of a single ventricle (anatomical or functional); systemic venous return redirected to PA, short-circuiting the subpulmonary ventricle

PREREQUISITES: **Mean PAP < 15 mmHg** with normal-sized PA, normal function of the single ventricle, absence of any significant AV valve regurgitation

STEPS OF THE MODIFIED FONTAN PROCEDURE: **1) Bidirectional cavopulmonary connection (bidirectional Glenn)**: connection between the SVC and R or L pulmonary arteries; **2) Connection of IVC to PA** (lateral conduit or extracardiac conduit or intracardiac conduit) with pulmonary trunk ligation



FACTORS OF HEMODYNAMIC DETERIORATION

a) Any ↗ filling pressure of the systemic ventricle
b) Obstruction to systemic venous return (thrombosis or obstruction of Fontan; ↗ PVR; pulmonary arteries stenosis; pulmonary vein compression)
c) Arrhythmia (risk of hemodynamic deterioration and thrombus)

CLINICAL FEATURES: JVD but nonpulsatile; single S1 and S2; absence of murmur (except in the case of AV valve regurgitation or subaortic obstruction); hepatomegaly / leg edema / ascites

COMPLICATIONS

a) **Intra-Fontan thrombus**: predisposed by stasis and atrial arrhythmia; leads to Fontan obstruction / pulmonary embolism / paradoxical embolism
b) **Fontan obstruction** (at anastomotic sites or by thrombus)
c) **Right pulmonary vein compression** by the interatrial septum or the dilated RA
d) **Arrhythmia**: IART; flutter; AF; SSS; AV block
e) **Cyanosis in the presence of a R→L shunt:** systemic venous collateral to pulmonary veins; pulmonary AVM; residual ASD; fenestrated Fontan; hepatopulmonary syndrome
f) **Ventricular dysfunction / systemic AV valve regurgitation**
g) **Protein-losing enteropathy:** anasarca; diarrhea; ↗ fecal alpha-1-antitrypsin and hypoalbuminemia
h) **Congestive hepatopathy** (or even cardiac cirrhosis)

MANAGEMENT

a) **A/C** if thrombus or stasis or thromboembolism or ASD or fenestration or atrial arrhythmia
b) **Single-ventricle failure**: consider ACE inhibitors - BB; sildenafil; transplant; mechanical support
c) **Aggressive treatment of atrial arrhythmias:** look for a hemodynamic cause; TEE prior to ECV; AAD; A/C; catheter ablation; conversion to extracardiac Fontan with intraoperative Maze
d) **When a pacemaker is indicated**: epicardial ventricular lead
e) **Protein-losing enteropathy**: diuretics - aldactone; eliminate obstruction or arrhythmia; dietary support; IV albumin; corticosteroids; sildenafil; Fontan fenestration; transplant

INDICATIONS FOR REOPERATION (I;C)

a) **Obstruction** to systemic venous return (revision of the Fontan or angioplasty / stenting or conversion of Fontan or thrombectomy)
b) **Obstruction** to pulmonary venous return (conversion to extracardiac Fontan)
c) Moderate-to-severe systemic AV valve **regurgitation**
d) **Symptomatic cyanosis** with venovenous collaterals or pulmonary AVM (catheter occlusion)
e) Residual ASD or fenestrated Fontan with significant R→L shunt (percutaneous closure)
f) **Subaortic stenosis** with peak-to-peak gradient > 30 mmHg
g) **Protein-losing enteropathy** with Fontan obstruction (revision of the Fontan or angioplasty / stenting) or with elevation of systemic venous pressures (consider fenestration)
h) **Symptomatic and refractory atrial arrhythmia** (conversion to extracardiac Fontan with intraoperative Maze)

PREGNANCY: increased risk of all Fontan-specific complications; risk of spontaneous abortion / IUGR / prematurity; follow-up by an experienced, multidisciplinary team

7.16/ EISENMENGER SYNDROME

Obstructive pulmonary vascular disease secondary to communication between pulmonary and systemic circulations (L→R shunt), leading in the long term to irreversible elevation of PAP and PVR (to systemic levels) and reversal of the shunt (R→L)

CLINICAL FEATURES: Central cyanosis (differential cyanosis in the presence of patent ductus arteriosus); clubbing; JVD (prominent A wave; prominent V wave in the presence of TR); signs of PHT

ECG: RAH; RVH; right axis deviation; atrial arrhythmia

CXR: dilatation of central pulmonary arteries ± calcification; dilatation of right chambers

COMPLICATIONS

a) **RV dysfunction**
b) **Complications of cyanotic heart disease:** erythrocytosis; bleeding; CRF; hyperuricemia / gout; cholelithiasis
c) Intrapulmonary hemorrhage / hemoptysis
d) Pulmonary artery aneurysm
e) Pulmonary artery thrombosis / Pulmonary embolism
f) Stroke - TIA; paradoxical embolism
g) Brain abscess
h) Arrhythmias: AF; flutter; VT
i) Sudden death
j) Endocarditis

MANAGEMENT

a) Correct iron deficiency, when present
b) Aggressive treatment of arrhythmia
c) Noncardiac surgery: multidisciplinary preoperative assessment in a tertiary institution
d) Pregnancy contraindicated
e) Avoid dehydration - hemorrhage - anemia
f) Avoid NSAID - vasoactive agents (which ↗ the shunt and cyanosis) - estrogens - nephrotoxins
g) Air filter on IV lines
h) Avoid vigorous physical exercise
i) Dental hygiene and prophylactic antibiotics
j) Investigate hemoptysis (CXR; CBC; CT scan; embolization PRN)
k) Influenza - pneumococcus vaccination

TREATMENT OF PHT

a) First-line endothelin antagonists (Bosentan; Macitentan)
b) PDE-5 inhibitors or prostanoids

LUNG ± HEART TRANSPLANT: in the case of refractory symptoms with estimated 1-year survival < 50%; contraindicated in the presence of multiple pleuropulmonary collaterals

7.17/ CYANOTIC HEART DISEASE

R→L shunt (deoxygenated blood enters the systemic circulation); chronic hypoxemia

SECONDARY ERYTHROCYTOSIS (↗ EPO)

- **Hyperviscosity (Hct > 65% and Hb > 20 g/dL)**: headache; faintness; tiredness; disorders of concentration; visual disorders; paresthesia; tinnitus; myalgia; intraoperative bleeding
  - **Treatment:** phlebotomies (if patient is iron-repleted and well hydrated)
  - **Treat any iron deficiency** (as microcytosis can cause hyperviscosity and is a risk factor for stroke); beware of rebound effect
- **Bleeding / clotting abnormalities** (if severe bleeding: FFP; vitamin K; cryoprecipitates; DDAVP; platelets)

OTHER COMPLICATIONS: Stroke - TIA; cerebral hemorrhage; paradoxical embolism; brain abscess; CRF; proteinuria; hyperuricemia; gout; hypertrophic osteoarthropathy (arthralgia); scoliosis; cholelithiasis

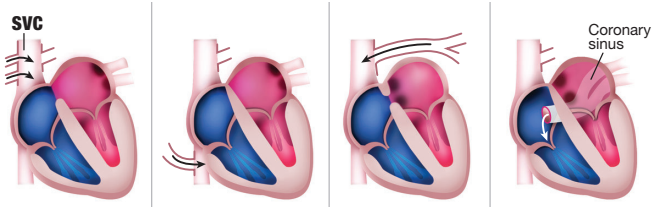
- Beware of nephrotoxic agents, including contrast agents

BASIC WORK-UP: SaO_2; CBC; ferritin; transferrin; iron saturation; ± folate; ± vitamin B12; PT-PTT; renal function; uric acid

PALLIATIVE SHUNTS (systemic to pulmonary): objective: improve pulmonary blood flow and cyanosis

- **Blalock-Taussig**: subclavian artery to pulmonary artery (modern: graft connecting the two arteries, preserving perfusion of the upper limb)
- **Waterston**: Ascending Ao to right PA
- **Potts**: Descending Ao to left PA
- **Physical examination:** Continuous murmur (except in the presence of stenosis / occlusion / significant PHT)
- **Complications**: PHT; distortion of PAs; stenosis / aneurysm at the site of anastomosis; heart failure (volume overload); arrhythmias

7.18/ ANOMALOUS PULMONARY VENOUS RETURN



RPV TO SVC (WITH SINUS VENOSUS ASD) | RPV TO IVC (SCIMITAR) | LPV TO INNOMINATE VEIN | LPV TO CORONARY SINUS

CONSEQUENCES AND CLINICAL FEATURES: similar to ASD

INDICATION FOR SURGERY: dilatation of right chambers

SCIMITAR SYNDROME: **pulmonary veins (right lung) drain into the IVC; scimitar appearance on CXR**; ± hypoplasia of right lung

7.19/ CONGENITAL CORONARY ARTERY ANOMALIES

ECTOPIC ORIGIN OF A CORONARY ARTERY

1 % of the population

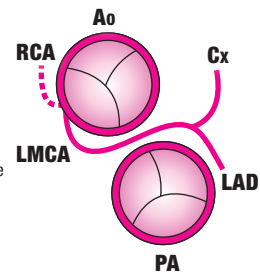
CLINICAL FEATURES: sudden death; retrosternal chest pain; arrhythmia; LV dysfunction; syncope

DETECTION: coronary CT angiography (or cardiac MRI); cholelithiasis

› Look for ventricular arrhythmia during exercise testing

INDICATIONS FOR SURGERY
(reimplantation; marsupialization)

a) Coronary artery coursing between the great vessels with **documented ischemia** (I;B)
b) Ectopic origin of **LMCA** (opposite sinus) coursing between the Ao and the PA (I;B)
c) Ectopic origin of the **right coronary artery** (opposite sinus) coursing between the Ao and the PA with documented ischemia (I;B)
d) Ectopic origin of the **LAD** coursing between the Ao and the PA (IIb;C)



ALCAPA SYNDROME

Anomalous left coronary artery arising from the pulmonary artery

CLINICAL FEATURES: ischemia; LV dysfunction; MI; ventricular arrhythmia; sudden death; may be well tolerated in the presence of collaterals of the RCA

INDICATIONS FOR SURGERY (coronary reimplantation)

› All patients with **ALCAPA syndrome** (I;C)

CORONARY ARTERIOVENOUS FISTULA

Communication between a coronary artery and a heart chamber (RA; RV) or a vein (coronary sinus; vena cava; pulmonary vein) or sometimes the PA

CLINICAL FEATURES: continuous left parasternal murmur

COMPLICATIONS

a) Dilatation of the nutrient coronary artery
b) Rupture - dissection
c) Myocardial ischemia distal to the fistula
d) Endarteritis
e) Left heart failure

INDICATIONS FOR SURGERY (percutaneous closure by embolization or surgical closure)

a) Large fistula - Qp:Qs > 1.5 : 1 (I;C)
b) Small to moderate fistula with: ischemia or arrhythmia or LV dysfunction or LV dilatation or endarteritis (I;C)

CONGENITAL SINUS OF VALSALVA ANEURYSM

RUPTURE: Sudden chest pain and dyspnea; continuous AV shunt with possible left and right heart failure; bounding pulse; continuous murmur ± thrill

a) Ruptured aneurysm of the right sinus of Valsalva: Ao - RVOT fistula
b) Ruptured aneurysm of the non-coronary sinus: Ao - RA fistula
c) Ruptured aneurysm of the left sinus of Valsalva: Ao - LA fistula

DDX: Infectious (endocarditis); Inflammatory - Vasculitis; Marfan; Iatrogenic

MYOCARDIAL BRIDGE ("MILKING")

Intramyocardial coronary segment (usually LAD)

Compression of the coronary segment with each systole

CONSEQUENCES: usually none; sometimes ischemia - angina - LV dysfunction - arrhythmia / VT - sudden death

MANAGEMENT: BB; CCB; PCI or CABG if severe refractory ischemia

7.20/ VASCULAR RING

Malformation of the aortic arch associated with **compression of the esophagus and/or trachea** (dysphagia, respiratory symptoms, stridor)

a) Double aortic arch
b) Right aortic arch; associated with Kommerell's diverticulum compressing the trachea (diverticulum at the junction of the left subclavian artery and the descending aorta)
c) Aberrant origin of the right subclavian artery (posterior to the esophagus)
d) Retroesophageal descending aorta (compression of the trachea)

7.21/ COR TRIATRIATUM

Fibromuscular diaphragm dividing the LA into two chambers

Severity varies according to the degree of stenosis; nonobstructive form (benign) versus obstructive form (leads to PHT)

Management similar to that of MS

7.22/ HEART DISEASE IN PREGNANT WOMEN

HEMODYNAMIC CHANGES DURING PREGNANCY

HEMODYNAMIC CHANGES	CONSEQUENCES
↗ 40-50% of plasma volume	Risk of congestion
↗ 10-20% of HR	Poorly tolerated MS
↗ 30-50% of cardiac output	
↘ Peripheral resistance (especially ↘ DBP)	Tolerated poorly stenotic lesions (increased gradient)
↗ Venous pressure in legs	Risk of stasis / DVT
Hypercoagulability	Increased thromboembolic risk

NORMAL PHYSICAL EXAMINATION OF THE PREGNANT WOMAN

↗ HR; normal or slightly ↗ CVP; Hyperdynamic state (pulse; apex); Apex may be broadened and slightly lateralized; leg edema is frequent

Accentuated S1 - accentuated splitting; S2 may appear to be constantly split at the end of pregnancy; S3 is frequent; left parasternal ejection murmur ≤ 3/6; continuous murmur (cervical venous "hum" or breast murmur)

MATERNAL RISK OF CARDIAC EVENTS

STRESS TEST: high-risk pregnancy if < 70% of predicted functional capacity

CARPREG SCORE (1 point each):

1) History of heart failure - TIA - Stroke - Arrhythmia 2) NYHA ≥ III or cyanosis 3) Mitral valve area < 2 cm² or Aortic valve area < 1.5 cm² or LVOT gradient > 30 mmHg 4) Systemic ventricle systolic function < 40%	Risk of cardiac event during pregnancy: • 0 point: 5 % • 1 point: 27 % • ≥ 2 points: 75 %

* Does not take PHT - mechanical valve - aortopathy into account

Siu SC, Sermer M, Colman JM, et al. Circulation 2001; 104:515–521.

WHO CLASSIFICATION

STAGE I: LOW-RISK PREGNANCY

- Uncomplicated, small or mild PS or patent ductus arteriosus or MVP
- Successfully repaired simple lesions (ASD; VSD; patent ductus arteriosus; anomalous pulmonary venous drainage)
- Isolated APC and PVC

STAGE II: MILD-TO-MODERATE RISK PREGNANCY

- Unrepaired ASD or VSD
- Repaired TOF
- Most arrhythmias

Stage II or III, depending on severity

- Mild LV dysfunction
- HCM
- Valvular heart disease not considered to be WHO stage I or IV
- Marfan syndrome without Ao dilatation
- Bicuspid aortic valve with Ao < 45 mm
- Repaired CoA

STAGE III: HIGH-RISK PREGNANCY (EXPERT FOLLOW-UP RECOMMENDED)

- Mechanical valve
- Systemic RV
- Fontan
- Cyanotic heart disease
- Complex congenital heart disease
- Marfan: Ao 40-45 mm
- Bicuspid aortic valve: Ao 45-50 mm

STAGE IV: PREGNANCY CONTRAINDICATED

- **Severe pulmonary arterial hypertension**
- **Severe LV dysfunction (LVEF < 30% - NYHA III or IV)**
- **Previous peripartum cardiomyopathy with residual impairment of LV function**
- **Severe MS or severe AS**
- **Marfan: Ao > 45 mm**
- **Bicuspid aortic valve: Ao > 50 mm**
- **Unrepaired CoA**

BICUSPID AORTIC VALVE STENOSIS

Pregnancy contraindicated if ascending Ao > 50 mm (or > 25 mm/m²)

› In the presence of Ao dilatation: TTE every 4-8 weeks; BB

SEVERE AORTIC STENOSIS: avoid pregnancy (particularly if symptoms or LV dysfunction or abnormal stress test); risk of hemodynamic instability during delivery; percutaneous valvuloplasty PRN in the presence of severe symptoms

MITRAL STENOSIS

Moderate-to-severe MS is poorly tolerated; deterioration due to tachycardia and ↗ cardiac output; risk of pulmonary congestion and PHT

BB (Metoprolol); valvuloplasty PRN if refractory NYHA III-IV

MITRAL REGURGITATION AND AORTIC REGURGITATION

Generally well tolerated if moderate regurgitation / NYHA ≤ II / normal LV function and dimensions

Diuretics and vasoactive agents PRN; Surgery if refractory NYHA III-IV

PROSTHETIC VALVE

Follow-up by an experienced multidisciplinary team

MECHANICAL VALVE: significant maternal and fetal risks

- Thromboembolic risk (hypercoagulability of pregnancy)
- Risk associated with anticoagulation (fetal loss; placental hemorrhage; insufficient anticoagulation; embryopathy; management during delivery)

UNFRACTIONATED HEPARIN (IV OR SC): less effective than warfarin; adjusted according to aPTT 6h post-injection (> 2 x normal)

LMWH: bid; dose according to **anti-Xa level 4 h post-injection (target: 0.8-1.2 IU/mL);** review once a week; replace by unfractionated heparin > 36 h before delivery

WARFARIN: risk of embryopathy during the first trimester (4-10%); **lower risk with Warfarin ≤ 5 mg daily**

WARFARIN DOSE ≤ 5 MG QD: continue Warfarin; replace by unfractionated heparin at the end of pregnancy prior to planned delivery

WARFARIN DOSE > 5 MG QD: LMWH or IV Heparin during first trimester; replace by Warfarin for 2nd and 3rd trimesters; then replace by unfractionated heparin prior to planned delivery

CYANOTIC HEART DISEASE

Pregnancy contraindicated if SaO_2 < 85 %

R→L shunt increased by ↘ peripheral resistance

Maternal hypoxia alters fetal growth and survival

PULMONARY HYPERTENSION

Pregnancy contraindicated in the presence of severe pulmonary hypertension

EISENMENGER: **maternal mortality as high as 50%**

DILATED CARDIOMYOPATHY

Avoid pregnancy if LVEF < 40%

PERIPARTUM CARDIOMYOPATHY

DEFINITION: "Idiopathic" cardiomyopathy with LV systolic dysfunction occurring around the last month of pregnancy or during the first 5 months post-partum

- Diagnosis of exclusion

RISK FACTORS: twin pregnancy, African American mother, advanced age, pre-eclampsia, smoking

MANAGEMENT: **A)** Hydralazine / Nitrates; **B)** BB (avoid Atenolol and Carvedilol; prefer beta-1 selective BB; Metoprolol is the best studied BB during lactation); **C)** Digoxin; **D)** Diuretics; **E)** Anticoagulate if intracardiac thrombus or LVEF < 35% or concomitant Bromocriptine

- ACE inhibitors (Captopril; Enalapril) are safe while breastfeeding
- Possible benefit of post-partum Bromocriptine (2-5 mg/day)
- Continue therapy with standard HF medications for ≥ 12 months

Normalization of LVEF in 50% of women (2 to 6 months)

Avoid subsequent pregnancy **(30% recurrence rate)**

HYPERTROPHIC CARDIOMYOPATHY

Autosomal dominant; variable penetrance

High-risk pregnancy if symptoms at baseline or significant baseline LVOT gradient

HYPERTENSION

PRE-EXISTING HTN: before pregnancy or < 20 weeks; rule out CoA

GESTATIONAL HYPERTENSION: *de novo* HTN (> 20 weeks after start of pregnancy); BP > 140/90 on 2 occasions; absence of proteinuria; returns to normal during the first 12 weeks postpartum

- **Management**: Labetalol; Methyldopa; Nifedipine

PRE-ECLAMPSIA: gestational HTN with the presence of proteinuria **(> 300 mg/24 h or > 30 mg/mmol on urine spot test**

- **Risk factors:** primiparous; twin pregnancy; ≥ 40 years; BMI ≥ 35 kg/m^2; family history of preeclampsia
- **Clinical features:** headache, blurred vision, abdominal pain, thrombocytopenia, abnormal LFTs, hemolysis, hyperreflexia - clonus, seizures, acute pulmonary edema, stroke
- **Management:** rest; sodium restriction; magnesium sulphate; delivery; IV Labetalol; Methyldopa; Nifedipine; IV Nitroglycerin; target SBP 140 to 160 mmHg and DBP 90 to 105 mmHg

ATRIAL FIBRILLATION

Anticoagulant according to embolic risk

CONTROL HR: Digoxin; BB (Metoprolol); CCB (Verapamil)

CONTROL RHYTHM: ECV; CCV (Procainamide); Flecainide / Sotalol

Continuous fetal monitoring during intervention / AAD

SUPRAVENTRICULAR TACHYCARDIA

ACUTE: Vagal maneuver or Adenosine or ECV; Metoprolol PRN; IV Procainamide; Continuous fetal monitoring during intervention

PROPHYLAXIS: Metoprolol or Digoxin; Flecainide / Sotalol PRN; Verapamil or ablation as 3rd line

CONTRACEPTION

Avoid estrogens in women with cyanotic heart disease, AF or flutter, mechanical prosthetic valve, Fontan, thromboembolic history or LVEF < 40%

Peripheral Vascular Disease

08

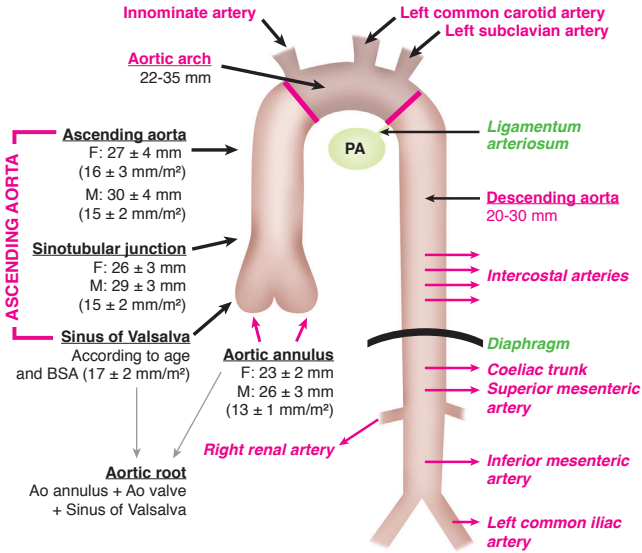
8.1/ Aneurysm of the thoracic aorta 276
8.2/ Acute aortic syndrome 279
8.3/ Abdominal aortic aneurysm (AAA) 282
8.4/ Other aortic diseases 283
8.5/ Peripheral artery disease (PAD) 285
8.6/ Atherosclerotic renovascular disease 289
8.7/ Cerebrovascular disease 290
8.8/ Pulmonary embolism 295
8.9/ Heparin-induced thrombocytopenia (HIT) 300
8.10/ Pulmonary hypertension 301

8.1/ ANEURYSM OF THE THORACIC AORTA

ANEURYSM: permanent and localized dilatation of an artery; **diameter > 150 %** of normal diameter (for age / gender / BSA)

- **Ectasia**: arterial dilatation < 150% of normal diameter
- **Pseudo-aneurysm (false aneurysm)**: **rupture** of arterial wall contained by hematoma and adjacent tissues

NORMAL DIMENSIONS



RISK FACTORS

- **Atherosclerotic / Degenerative** (media degeneration): HTN; smoking; COPD; family history
- **Congenital**: Bicuspid aortic valve; Tetralogy of Fallot; CoA; VSD; Transposition of great arteries
- **Genetic**: Marfan; Ehlers-Danlos type IV; Turner; Loeys-Dietz; Noonan; Familial thoracic aortic aneurysm syndrome
- **Inflammatory**: Takayasu; Giant cell arteritis; Behçet; Ankylosing spondylitis; Spondyloarthropathies; SLE; Sarcoidosis
- **Infectious**: Syphilis; Salmonella; Staphylococcus; HIV

PRESENTATION: Asymptomatic; Aortic dissection; Aortic rupture; AR; Infectious aortitis; Compressive symptoms (recurrent laryngeal nerve; trachea; esophagus; SVC syndrome); Pain (neck; jaw; back; interscapular); Embolism (thrombus or cholesterol crystals); Fistula (aortoesophageal; aortobronchial)

ECHOCARDIOGRAPHY: diameter at end-diastole using the leading-edge of the anterior wall to the leading of the posterior wall

CT SCAN AND MRI: measurement of outer diameter

CXR: large mediastinum; prominent aortic knob; trachea deviated to the right

MANAGEMENT

RISK FACTOR CONTROL: HTN; Lipids; Smoking

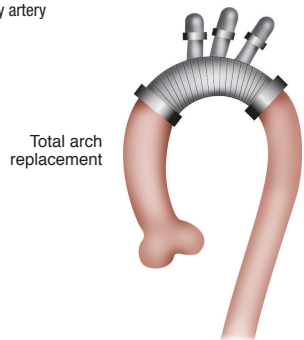
BB AND ACE INHIBITORS / ARB

AVOID ISOMETRIC EXERCISES

INDICATIONS FOR SURGERY – ASCENDING AORTIC ANEURYSM	
Degenerative ascending aortic aneurysm	**≥ 55 mm**
Progressing aneurysm	**> 5 mm / year**
Symptomatic aneurysm	Compressive symptoms; Pain
Ao valve or CABG surgery	**> 45 mm**
Bicuspid aortic valve	**> 55 mm (or > 50 mm with family history of dissection or progression ≥ 5 mm / year)**
Marfan	**40-50 mm** (▸▸| Genetic aortic syndromes)
Marfan or Genetic Syndrome or Bicuspid aortic valve	**Maximum Ao area (cm²) / Patient's height (m) > 10**
Lœys-Dietz	**≥ 42 mm** (TEE) or **≥ 44 mm** (CT or MRI)
Turner	**> 25 mm/m²**
SURVEILLANCE – ASCENDING AORTIC ANEURYSM	
Aneurysm 35 - 44 mm	• Ensure stability with follow-up assessment 6 months after diagnosis • Stable → Imaging every 1-3 years **(progression ≈ 1 - 2 mm / year)**
Aneurysm 45 - 54 mm	Imaging after 3-6 months (stability) then every 6-12 months
Pregnancy	Imaging every 6-8 weeks (until 3 months postpartum)

ANEURYSM OF AORTIC ARCH

SURGERY: requires profound hypothermia and circulatory arrest; temporary cerebral perfusion via the right axillary artery



SURGICAL OPTIONS: Resection of the proximal hemi-arch; Total arch replacement; Stent with reimplantation of innominate arteries...

› **Elephant trunk procedure**: aneurysm of the aortic arch and descending aorta; allows subsequent stenting of the descending aorta

MANAGEMENT – ANEURYSM OF THE AORTIC ARCH	
Isolated aneurysm of the aortic arch > 55 mm or compressive symptoms	Surgery (if acceptable surgical risk)
Aneurysm of the aortic arch < 40 mm	Imaging every 1-2 years
Aneurysm of the aortic arch > 40 mm	Imaging every 6-12 months

ANEURYSM OF THE DESCENDING THORACIC AORTA

MANAGEMENT – ANEURYSM OF THE DESCENDING THORACIC AORTA	
Degenerative or traumatic aneurysm > 55 mm	TEVAR (when technically feasible)
Chronic dissection + [refractory symptoms or aneurysm > 55 mm or progression of diameter > 4 mm/year]	TEVAR (open surgery when TEVAR is contraindicated)

SURGICAL PROCEDURE: CPB with retrograde femoral perfusion

› **Risk of spinal cord ischemia**

THORACIC ENDOVASCULAR AORTIC REPAIR (TEVAR): stent deployment requires a normal aortic segment > 20 mm above and below the aneurysm (with diameter < 40 mm) and adequate vascular access

› **Contraindications**: Severe Ao atherosclerosis (risk of atheroembolism); severe PAD (limiting femoral access)

› **Regular long-term surveillance following TEVAR:** CTscan or MRI after 1, 6 and 12 months and then yearly (or every 2 years if stable course)

› **Complications**: Stroke; Atheroembolism; Spinal cord ischemia; Paraplegia; MI; Ventricular arrhythmia; ARF; Transformation from type B to type A dissection; Stent fracture; Stent migration; Infection; Occlusion of arterial branches (subclavian; mesenteric; celiac trunk; renal)

- **Endoleak**: persistence of blood flow outside of the stent lumen towards the aneurysm sac

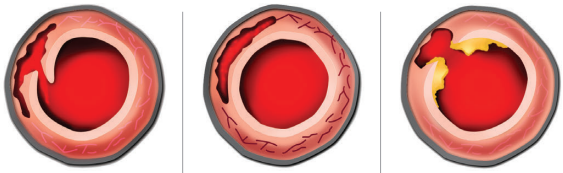
TYPE I ENDOLEAK	Reperfusion and filling of the aneurysm sac via a leak in the proximal or distal portion of the stent (requires treatment)
TYPE II ENDOLEAK	Retrograde flow in the aneurysm sac via a branch artery (intercostal; lumbar; mesenteric) (observation)
TYPE III ENDOLEAK	Separation of stent components (fracture; separation) (requires treatment)

8.2/ ACUTE AORTIC SYNDROME

AORTIC DISSECTION

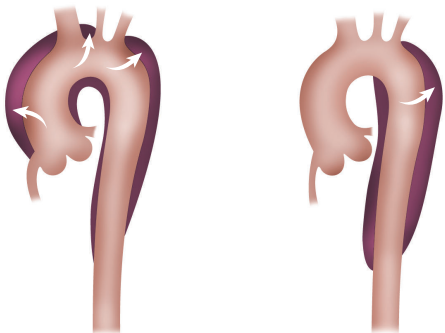
Tear of the media with bleeding inside the media and along the arterial wall

Acute aortic syndrome



Ao dissection | **Intramural hematoma** | **Penetrating atherosclerotic ulcer**

STANFORD CLASSIFICATION	
Type A	Involves the ascending Ao
Type B	No involvement of the ascending Ao
DEBAKEY CLASSIFICATION	
Type I	Ascending Ao → extends at least to the aortic arch (± descending Ao)
Type II	Confined to the ascending Ao
Type III	Confined to the descending Ao



Type A Ao dissection
Involvement of the ascending Ao
(Surgical management)

Type B Ao dissection
No involvement of the ascending Ao
(Initially medical treatment)

RISK FACTORS

↗ AORTIC STRESS	DEGENERATION OF THE MEDIA
• Aortic aneurysm • Aortic valve disease • HTN • CoA • Recent aortic intervention • Trauma / Deceleration • Pheochromocytoma • Cocaine • Weightlifting • Penetrating ulcer • Infectious aortitis	↗ metalloproteinases; ↘ elastic fibers; ↗ proteoglycans • **Degenerative / Atherosclerotic** • **Genetic**: Marfan; Ehlers-Danlos type IV; Bicuspid aortic valve; Turner; Loeys-Dietz; Familial thoracic aortic aneurysm and dissection • **Vasculitis**: Takayasu; Giant cell arteritis; Behçet • **Other**: Pregnancy; Polycystic kidneys; Chronic corticosteroid therapy

PRESENTATION: Acute - severe - tearing pain; Retrosternal pain (type A) or back pain (type B)

- **Target organ ischemia:** Myocardial infarction; Stroke - TIA; Spinal cord ischemia (paraplegia / parapharesis) or mesenteric or renal or lower limbs; Ischemic neuropathy
- **Hemorrhagic**: Tamponade; Hemothorax; Hemomediastinum; Aortopulmonary or aorto-enteric or aorto-esophageal fistula
- **Aortic regurgitation**: Mechanisms: **A)** Aortic root dilatation (malcoaptation); **B)** Dissection involving a leaflet implantation site (leaflet prolapse); **C)** Transvalvular prolapse of the dissection flap; **D)** Underlying AR (bicuspid aortic valve)

CLINICAL FEATURES: Hypotension or Normotension or Hypertension (**measure BP in both arms**); Absent pulses (evaluate pulses in all extremities); **AR murmur**; Signs of tamponade; Neurological deficits; Abdominal signs

TEE: Dissection flap separating the true lumen and the false lumen (with independent movement); two flows on either side of the dissection flap on color Doppler; thrombus in the false lumen; look for the entry site and/or exit site of the dissection; pericardial effusion; myocardial ischemia (RWMA); AR; coronary ostia

	TRUE LUMEN	FALSE LUMEN
Size	True < False	False > True
Pulsation	Systolic expansion	Systolic compression
Direction of flow	Anterograde (systolic)	Retrograde or ↘ Anterograde systolic flow
Thrombus	Rare	Common
Contrast agent	Rapid opacification	Delayed opacification

CXR

a) **Aortic shadow** abnormal and enlarged
b) **Large mediastinum**: **AP CXR → > 8 cm at the carina**
c) **Calcium sign**: separation between calcification of the aortic intima and the lateral wall of the aortic knob **> 10 mm**
d) **Pleural effusion** (inflammatory reaction or hemothorax)
e) **Deviation of the trachea** towards the right (or deviation of the esophagus - NGT)
f) **Pulmonary edema** (AR)

PREOPERATIVE CORONARY ANGIOGRAPHY: it is reasonable not to perform coronary angiography in acute aortic syndrome, which constitutes a surgical emergency (class IIa recommendation)

POSTOPERATIVE COMPLICATIONS: Aneurysm formation (at the site of dissection or at the site of anastomosis or elsewhere); Recurrent dissection; Graft dehiscence; Pseudoaneurysm; AR; Infection; Progression of false lumen

FOLLOW-UP BY CT ANGIOGRAPHY OR MR ANGIOGRAPHY: 1-3-6-12-18-24 months; then annually +

- **Tybe B aortic dissection: TEVAR or surgical repair if aneurysm > 55-60 mm or > 4 mm/year growth or target organ ischemia or recurrent pain**

AVOID ISOMETRIC EXERCISES; CONTROL BP

SPONTANEOUS INTRAMURAL HEMATOMA

Medial tear with bleeding inside the media, but absence of communication with the aortic lumen (absence of false lumen)

- Can propagate in an anterograde or retrograde fashion
- **May have an identical clinical presentation to that of aortic dissection**

IMAGING: Intramural thrombus; Enlarged wall **> 5 mm** (crescent-shaped or circular); Absence of flow (contrast) in wall +

COURSE: Resolution or stabilization or aneurysm formation or progression to aortic dissection or aortic rupture

MANAGEMENT: Similar to aortic dissection (for corresponding segment)

a) **Ascending Ao** → urgent surgery
b) **Descending Ao** → initial medical treatment; Indication for TEVAR (or surgery) according to aortic diameter or persistent symptoms or progression or compromise of branches (with ischemia)

PENETRATING ATHEROSCLEROTIC ULCER

Penetration of the aortic wall by an atherosclerotic ulcer (± secondary intramural hematoma); descending aorta in the majority of cases

COMPLICATIONS: Aortic dissection; Aortic rupture; Distal embolism (thrombus or cholesterol crystals); Aneurysm

MANAGEMENT

a) **Ascending Ao** → Surgery should be considered
b) **Descending Ao** → Initial medical treatment; Indication for TEVAR (or surgery) according to aortic diameter or persistent symptoms or progression or deteriorating associated intramural hematoma

8.3/ ABDOMINAL AORTIC ANEURYSM (AAA)

ANEURYSM: **Abdominal Ao diameter > 30 mm**

- Predominantly occurs in the infrarenal aorta
- Degeneration of the media (↗ metalloproteinases)
- **Risk factors**: Smoking; Family history; Age; Male gender; COPD; dyslipidemia; HTN

PRESENTATION: Asymptomatic; Embolism; Rapid expansion; Pain; Compression or erosion of adjacent structures; Rupture

ABDOMINAL ULTRASOUND: High sensitivity and specificity

- **Screening**: Male, 65 to 74 years with history of smoking; Male ≥ 60 years with family history of AAA

MANAGEMENT: Smoking cessation; treatment of HTN - dyslipidemia - DM; Surveillance of AAA

AAA REPAIR: Surgical or Percutaneous (EVAR) in a patient with **life expectancy > 2 years**

MANAGEMENT – ABDOMINAL AORTIC ANEURYSM	
Indication for aneurysm repair (EVAR or open surgery)	• ≥ 55 mm or • Symptoms (pain) or • Progression > 10 mm per year (> 5 mm over 6 months) or • Infectious or inflammatory
AAA 30-39 mm	Surveillance every 3 years (progression ≈ 3 mm per year)
AAA 40-44 mm	Surveillance every 2 years
AAA > 45 mm	Surveillance every year

EVAR: endovascular AAA repair (for infra-renal AAA); anatomical suitability → proximal aortic neck (segment between the lowest renal artery and the proximal extent of the aneurysm) > 10-15 mm of length (and < 32 mm in diameter); adequate vascular access required

★ EVAR and ★ DREAM: surgical versus endovascular AAA repair; ↘ operative mortality with EVAR; **similar long term mortality; ↗ reintervention with EVAR**

SURGICAL AAA REPAIR SHOULD BE PREFERRED: anatomical criteria for EVAR not met or when regular long-term surveillance is impossible

- **Regular long-term surveillance following EVAR:** CT angiography or MR angiography at 1 month - 6 months - then annually; look for endoleakage, stent position, stability and exclusion of the aneurysm sac, stent fracture
- **Late complications of surgery**: para-anastomotic aneurysm; graft infection; graft-enteric fistula; imaging every 5 years

PATIENTS NOT CANDIDATES FOR SURGERY: significant comorbidities → no benefit of EVAR on long term survival (★EVAR 2)

8.4/ OTHER AORTIC DISEASES

AORTIC ATHEROSCLEROTIC PLAQUE

COMPLEX PLAQUE: Plaque thickness ≥ 4 mm or mobile / pedunculated debris (= thrombus) or ulceration

- ↗ embolic risk
- **Site**: particularly in the distal aortic arch and descending aorta

EMBOLISM: spontaneous or iatrogenic (post-intervention)

- **Thrombus (thromboembolism)**: thrombus forms on an unstable plaque then embolizes to a medium-to-large artery (stroke; TIA; leg ischemia; renal or splenic infarction; mesenteric ischemia)
  - Consider anticoagulation if complex plaque in aortic arch with stroke / TIA (class IIb)
- **Cholesterol crystals (atheroembolism)**: crystal emboli to small arterioles ("blue toe"; retinal ischemia / Hollenhorst plaques; Amaurosis fugax; TIA; Confusion; ARF; HTN; *Livedo reticularis*; Petechiae; Purpura; Intestinal ischemia; Pancreatitis)
  - **Hypocomplementemia; Eosinophilia**
  - **Consider endarterectomy or stent** in the presence of an identified source of embolism and recurrent atheroembolism

MANAGEMENT: Secondary prevention; ASA - Statin - control HTN / DM; smoking cessation

GENETIC AORTIC SYNDROMES

SYNDROME	DETAILS	FOLLOW–UP	MANAGEMENT
Marfan	• FBN1 mutation • Dilatation of aortic root **(annulo-aortic ectasia)** and ascending Ao; **Type A dissection** • Ghent diagnostic criteria ▶▶| - Chapter 7	• TTE at diagnosis and after 6 months (stability) then every 6-12 months • Follow-up by imaging of the entire aorta following repair of the ascending Ao	• BB; Losartan • **Surgery**: **A)** > 50 mm; **B)** Progression > 5 mm/y; **C)** Family history of dissection < 50 mm; **D)** Significant AR • **Desire for pregnancy**: surgery if ≥ 40 mm
Lœys-Dietz	• Autosomal dominant • TGFBR1 or 2 mutation • Tortuosities / aneurysms / artery dissection • Hypertelorism; Cleft palate or bifid uvula • **Aneurysm of the aortic root; Aortic dissection**	• Imaging of the entire aorta at diagnosis and after 6 months (stability) • **Annual MRI of the cerebrovascular circulation and as far as the pelvis**	• **Surgery if ascending Ao ≥ 42 mm (TEE; inner diameter) or ≥ 44 mm (CT or MRI; outer diameter)**
Ehlers-Danlos Type IV	• Autosomal dominant (COL3A1) • **Risk of artery rupture** (including thoracic and abdominal aorta) • **Risk of rupture of the uterus / intestine**		• Role of prophylactic repair remains uncertain (friable tissues) • Follow-up by imaging
Turner	• 45, X • Small stature; Ovarian insufficiency • **Bicuspid aortic valve (20%); CoA (10%); Ao aneurysm; Ao dissection**	• Look for risk factors of aortic dissection (bicuspid aortic valve / CoA / dilatation of thoracic Ao / HTN) • **In the presence of risk factors:** annual TTE • **Otherwise**: TTE every 3-5 years	• Surgery if maximum Ao area (cm^2) / patient's height (m) > 10 • Surgery if diameter > 25 mm/m^2
Non-syndromic familial thoracic aortic aneurysm and dissection	• Non-syndromic • Autosomal dominant • Variable penetrance • **Genes identified:** TGFBR1 and 2; ACTA2; MYH11; MYLK; PRKG1	• **Family screening:** 1st degree relatives of patients with unexplained dissection or aneurysm • **Genetic testing** if several family members are affected	• TGFBR mutation: similar management to that of Loeys-Dietz

VASCULITIS WITH AORTIC INVOLVEMENT

Destruction of vessels (inflammation; ↗ metalloproteinases; granulomas)

Takayasu	• **Vasculitis of the aorta and its branches (stenosis and/or aneurysm)** • **Diagnostic criteria**: < 40 years; Claudication (upper limbs or lower limbs); ↘ Brachial pulse; Aortic or subclavian murmur; sBP Difference > 10 mmHg arms; Stenosis of the Ao or its branches (CT angiography or MR angiography) • **Treatment:** Prednisone 50 mg; MTX; Azathioprine; Anti-TNFalpha
Giant cell arteritis (temporal arteritis)	• **Vasculitis of the aorta and its branches** • **Diagnostic criteria**: > 50 years; *de novo* headache; tenderness over temporal artery (or ↘ pulse); ↗ ESR (> 50 mm/h); Positive biopsy • Constitutional symptoms; Claudication of the jaw; Claudication of upper limbs; Visual symptoms; PMR; Aortic aneurysm / dissection • **Treatment**: Prednisone 50 mg
Behçet	• **Diagnostic criteria**: Mouth ulcers; Genital ulcers; Uveitis or retinal vasculitis; Erythema nodosum; Pseudofolliculitis; Pathergy • **Arterial involvement**: destruction of the media; aneurysm ± rupture (any artery can be affected)
Ankylosing spondylitis	• HLAB27+ • **Diagnostic criteria:** < 40 years; Low back pain; Morning stiffness; Slow progression; Improvement with exercise • AR; Dilatation of the aortic root

TRAUMATIC AORTIC RUPTURE

Predominantly involves the **aortic isthmus** (deceleration injury)

BP in arms > BP in legs; radiofemoral delay; interscapular murmur

CXR: widened mediastinum; displaced nasogastric tube (hematoma); Dilatation of aortic arch / descending aorta; pleural effusion

MANAGEMENT: TEVAR if suitable anatomy (or open surgery)

INFECTIOUS AORTITIS

Contiguous invasion or septic embolism (endocarditis) or hematogenous spread

SITE: on a pre-existing aortic lesion (aneurysm; atherosclerotic plaque; site of iatrogenic injury); predominantly involves the infrarenal aorta

MICROORGANISMS: *S. aureus; Salmonella;* Streptocoque; *E. coli; Neisseria;* Fungi; TB; Syphilitic aortitis (10-25 years post-infection)

COMPLICATIONS: saccular aneurysm; fistula; pseudo-aneurysm; rupture

8.5/ PERIPHERAL ARTERY DISEASE

PAD: cardiovascular risk equivalent to that of CAD

› **5-year mortality**: 10-15% (75% from cardiovascular causes)

RISK FACTORS: Smoking; DM; HTN; Dyslipidemia; Age; CRF; Chronic inflammation

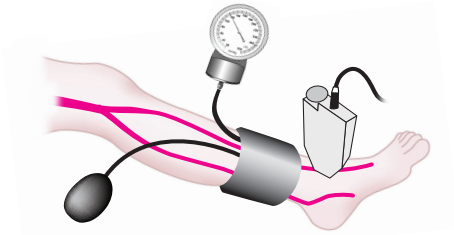
PRESENTATION: Asymptomatic; Intermittent claudication; Critical limb ischemia

CLINICAL FEATURES: ↘ pulse; murmur; pallor on elevation; ↗ erythema of limb in dependent position; coldness; muscle atrophy; hair loss; onychodystrophy; skin fissures; ulcers; devitalization - gangrene

FONTAINE CLASSIFICATION	
I	Asymptomatic
II	Intermittent claudication
IIa	Claudication > 200 m
IIb	Claudication < 200 m
III	Rest pain / night pain
IV	Ulcer / Gangrene

DDX: vasculitis (thromboangiitis obliterans; Takayasu; giant cell arteritis); CoA; fibromuscular dysplasia; external compression; radiotherapy; neurogenic claudication (lumbosacral radiculopathy); arthritis; myositis; venous insufficiency; popliteal artery entrapment syndrome

ANKLE-BRACHIAL INDEX



ABI ≤ 0.90	ABI 0.91 - 0.99	ABI 1.0 - 1.4	ABI > 1.4
Abnormal	**Gray zone**	**Normal**	**Calcified noncompressible artery**
• Mild: 0.8-0.9 • Moderate: 0.5-0.8 • Severe: < 0.5	ABI on exercise if persistent suspicion of PAD: diagnosis of vascular claudication if ABI ↘ by > 20-25 %		DM / CRF / Age → Use toe-brachial index (diagnostic if < 0.7)

ABI: ratio of sBP in ankle (posterior tibial artery or dorsalis pedis artery) / brachial artery

INDICATION FOR ABI: suspicion of PAD in the leg with:

› Suspected claudication; Poor wound healing; ≥ 50 years + [DM or Smoking]; ≥ 65 years; intermediate Framingham score

OTHER EXAMINATIONS: segmental BP measurements; Doppler US; MR angiography; CT angiography; Angiography

MANAGEMENT

MANAGEMENT OF RISK FACTORS: Smoking cessation; Statin; Treatment of DM (HbA1c < 7%); Control of BP; ACE inhibitors (★ HOPE)

ASA: ↘ mortality - stroke - myocardial infarction (★ Antithrombotic Trialists' Collaboration)

› **Indications**
  a) Symptomatic patient (claudication; critical limb ischemia; history of revascularization; history of amputation) (class I recommendation)
  b) Asymptomatic patient with ABI ≤ 0.90 (class IIa recommendation); limited evidence

› **Clopidogrel as alternative treatment**: superior to ASA in ★ CAPRIE; marginal benefit of ASA and Clopidogrel combination in ★ CHARISMA

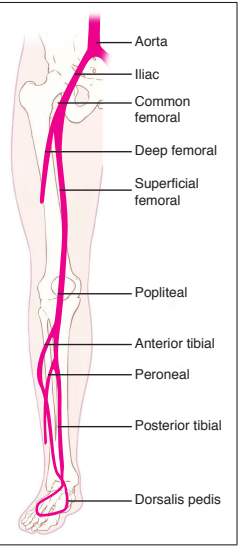
SUPERVISED EXERCISE PROGRAM: 30-45 min; 3 x / week ; > 12 weeks; ↗ exercise capacity

CILOSTAZOL (100 MG PO BID): phosphodiesterase-3 inhibitor; ↘ platelet aggregation; direct arterial vasodilator; contraindicated in the presence of heart failure; beware of drug interactions

PENTOXIFYLLINE (400 MG PO TID): phosphodiesterase inhibitor; ↘ blood viscosity; ↗ erythrocyte deformability; marginal efficacy

REVASCULARIZATION: Indications → **A)** Symptoms refractory to medical treatment with impaired quality of life; **B)** Critical limb ischemia

Aorto-iliac	• First-line endovascular revascularization (with stent) (TASC II type A - B - C) • Surgical revascularization: aortofemoral bypass graft with Dacron or PTFE prosthesis; femorofemoral bypass graft; axillofemoral bypass graft
Femoro-popliteal	• First-line endovascular revascularization (TASC II type A - B - C) • Stenting for intermediate length (TASC type II B) • Surgical revascularization: femoropopliteal bypass graft preferably with autologous venous conduit (or PTFE prosthesis)
Infra-popliteal (below the knee)	• Revascularization in the presence of persistent critical limb ischemia despite proximal revascularization • First-line endovascular revascularization • Stenting if suboptimal result • Surgical revascularization: femorotibial or femoroperoneal bypass graft (autologous venous conduit)



› **Mode of revascularization**: first-line endovascular treatment in most cases; decision by multidisciplinary team according to anatomy / durability / comorbidities / local expertise / patient preference
  • **Percutaneous revascularization**: medium- and long-term patency decreased in the presence of a distal lesion / lesion > 10 cm / multiple lesions / poor distal runoff / DM / CRF

- **Surgical revascularization:** preferred in the case of disseminated disease or technically difficult endovascular revascularization or TASC II type D (± type C)

› **Regular surveillance**: for all patients post-revascularization; history - ABI - physical examination; ± Doppler US (vein graft)

› **Antithrombotic therapy:** ASA for all patients; Clopidogrel 1 to 3 months post-stenting; consider Warfarin after bypass graft with vein graft

CRITICAL LIMB ISCHEMIA

DEFINITION: A) Ischemic pain at rest; B) Ischemic lesion (ulcer; gangrene)

› **sBP at ankle**: < 50 mmHg (rest pain) or < 70 mmHg (ischemic lesion)

ONE-YEAR MORTALITY: 25 %

MANAGEMENT: **A)** Analgesia; **B)** Urgent revascularization if tissues are still viable (endovascular if technically feasible); **C)** Amputation if tissues are devitalized; **D)** Secondary prevention - wound care - adjusted shoes - treatment of infectious complications

› ★ **BASIL**: revascularization by infrainguinal venous bypass graft similar to endovascular revascularization; ↘ reintervention with bypass graft; ↘ **mortality with bypass graft in patients surviving > 2 years**

ACUTE LIMB ISCHEMIA

MECHANISM: embolism (cardiac; Ao; peripheral arteries); thrombosis *in situ*; thromboembolism from a popliteal artery aneurysm (repair of aneurysm as primary prevention if > 20 mm); thrombosis of infrainguinal bypass graft; trauma; dissection; thrombophilia - hyperviscosity; *phlegmasia cerulea dolens*; iatrogenic (endovascular procedure; IABP; extracorporeal cardiac mechanical support)

PRESENTATION: Pain; Coldness; Pallor; Loss of pulse (Doppler PRN); Paresthesia / Sensory deficit; Weakness / Paralysis

MANAGEMENT: Medical emergency; **A)** IV Heparin; **B)** Percutaneous thromboembolectomy and/or direct intraarterial thrombolysis (first-line); **C)** Surgical revascularization (second-line)

ATHEROSCLEROSIS OF THE ARMS

Innominate / subclavian artery stenosis

SUBCLAVIAN STEAL SYNDROME: claudication of the arm; reversal of flow of the vertebral artery (vertigo; syncope; diplopia; dysarthria; ataxia) or of a mammary bypass graft (angina) to perfuse the arm

DETECTION: BP difference in arms ≥ 10 mmHg

TREATMENT: endovascular or surgical revascularization

8.6/ ATHEROSCLEROTIC RENOVASCULAR DISEASE

↘ Renal perfusion → activation of renin-angiotensin-aldosterone system → peripheral vasoconstriction + salt and water retention → HTN

BILATERAL RENAL ARTERY STENOSIS (OR FUNCTIONAL SOLITARY KIDNEY): ↗ BP (renin-angiotensin-aldosterone system) with salt and water retention in the absence of compensatory sodium excretion → flash pulmonary edema

CONSEQUENCES: Asymptomatic; HTN; Flash pulmonary edema - Diastolic dysfunction; Progressive deterioration of renal function (ischemic nephropathy; hypertensive nephropathy in contralateral kidney + proteinuria)

MANAGEMENT

POSSIBLE RENOVASCULAR HTN

a) Onset of HTN < 30 years (FMD) or > 55 years
b) Severe or refractory HTN
c) Underlying atherosclerosis
d) ↗ Creatinine ≥ 30% post-ACE inhibitors - ARB
e) Recurrent flash pulmonary edema
f) Unilateral atrophic kidney (asymmetry > 1.5 cm)

Screening → **DOPPLER US RENAL ARTERIES**

Diagnosis → **MR ANGIOGRAPHY OR CT ANGIOGRAPHY RENAL ARTERY ANGIOGRAPHY**

Renal artery stenosis

SECONDARY PREVENTION + ACE INHIBITORS (EXCEPT WHEN BILATERAL)

INDICATION FOR REVASCULARIZATION?

- Recurrent flash pulmonary edema
- Refractory HTN
- Progressive CRF (bilateral stenoses)

Yes

BENEFIT OF ANGIOPLASTY-STENTING?

	NORMAL PERFUSION	**ISCHEMIA** • FFR < 0.8 • Systolic gradient ≥ 20 mmHg • Technetium scan
NEPHROPATHY • Proteinuria • Atrophy • ↘ GFR • Resistance index > 0.8 (nephrosclerosis)	NO	±
NORMAL PARENCHYMA	NO	++

STUDY: no benefit with stenting in ★ CORAL

8.7/ CEREBROVASCULAR DISEASE

ETIOLOGIES – MECHANISMS

HEMORRHAGIC STROKE (20%)

INTRACEREBRAL HEMORRHAGE

RISK FACTORS: HTN; Trauma; Bleeding diathesis; Amyloid angiopathy; Vascular malformation; Tumor; Drugs

SUBARACHNOID HEMORRHAGE

- Ruptured aneurysm
- Explosive headache
- Blood in CSF

ISCHEMIC STROKE (80%)

ATHEROTHROMBOTIC (LARGE VESSELS)

- Intracranial or extracranial vessels
- Thrombosis *in situ* or Artery → artery embolism or Hypoperfusion
- ± Preceded by TIA in the same territory

CARDIOEMBOLIC

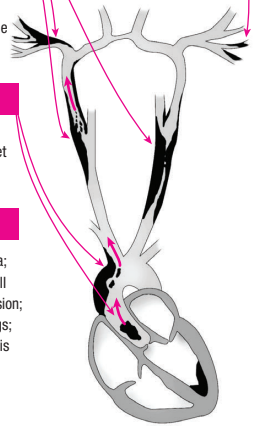
- Sudden onset
- Maximum deficit at onset
- Multiple territories

OTHER

Dissection; Thrombophilia; Hyperviscosity; Sickle-cell anemia; Systemic hypoperfusion; Arteritis; Vasospasm; Drugs; Cerebral venous thrombosis

LACUNAR (SMALL PENETRATING VESSELS)

- Lipohyalinosis (HTN; DM)
- Pure motor; Pure sensory; Hemiparesis / Ataxia; Dysarthria / Clumsy hand



TRANSIENT ISCHEMIC ATTACK (TIA)

TIA: transient episode (often < 1 h) of neurological dysfunction (focal cerebral or retinal or spinal ischemia) **in the absence of CNS infarction / permanent CNS injury**

ASSESSMENT: MRI (diffusion-weighted images - DWI) or brain CT scan; noninvasive imaging of head and neck vessels (carotid Doppler; CT angiography; MR angiography); ECG; TTE; ± TEE (cryptogenic TIA; suspicion of cardioembolic TIA); Holter; ± Evaluation of intracranial arteries (CT angiography or MR angiography or angiography or transcranial Doppler)

- **Evaluation of hereditary thrombophilia**: thrombophilia associated with venous >>> arterial thromboses; consider in the presence of cryptogenic TIA or suspected antiphospholipid syndrome (miscarriages; venous thrombosis; *livedo reticularis*) or personal or family history of systemic thrombosis
  - **Look for**: protein C or S or antithrombin III deficiency; Leiden factor V; prothrombin mutation G20210A; lupus anticoagulant; anticardiolipin antibody

EVALUATION OF THE SHORT-TERM RISK OF STROKE

ABCD² SCORE		
≥ 60 years	1 point	48-hour stroke risk 0-1: 0 % 2-3: 1 % 4-5: 4 % 6-7: 8 %
BP ≥ 140/90	1 point	
Dysphasia without weakness or Unilateral weakness	1 point 2 points	
Diabetes	1 point	
Duration 0-59 min Duration ≥ 60 min	1 point 2 points	

Rothwell OM, Giles MF, Flossmann E, et al. Lancet. 2005; 366: 29-36.
Johnston SC, Rothwell PM, Nguyen-Huynh MN, et al. Lancet. 2007; 369: 283-92.

CARDIOEMBOLIC SOURCE

ASSESSMENT: ECG; 24-hour monitor / Holter; TTE; TEE

› **Additional ambulatory electrocardiographic monitoring** beyond 24-hour for subclinical AF detection if cardioembolic TIA suspected (★ EMBRACE; ★ CRYSTAL-AF)

HIGH CARDIOEMBOLIC RISK	POTENTIAL CARDIOEMBOLIC RISK
• LA (LAA) or LV thrombus • AF - Flutter • Recent MI (< 1 month) • Rheumatic MS • Prosthetic valve • Severe LV dysfunction • Infective endocarditis • Noninfective endocarditis (Libman-Sacks; Antiphospholipid syndrome; Nonbacterial thrombotic endocarditis) • Myxoma - Fibroelastoma • ASD or VSD	• Complex atherosclerosis of the aorta • Aortic valve disease • Mitral annular calcification • MVP • PFO • Atrial septal aneurysm • LV aneurysm without thrombus • Spontaneous echo contrast in LA • Regional wall motion abnormality • HCM • LV noncompaction

ISCHEMIC STROKE

NIH STROKE SCALE (NIHSS): QUANTIFICATION OF NEUROLOGICAL IMPAIRMENT	
Level of consciousness	0 - Alert; 1 - Drowsy; 2 - Stuporous; 3 - Comatose
Orientation (2 questions)	0 - 2/2; 1 - 1/2; 2 - 0/2
Response to 2 commands	0 - 2/2; 1 - 1/2; 2 - 0/2
Gaze	0 - Normal lateral eye movements 1 - Partial gaze palsy 2 - Complete palsy
Visual fields	0 - No visual loss 1 - Partial hemianopia 2 - Complete hemianopia 3 - Bilateral hemianopia

Facial palsy	0 - Normal 1 - Minor paralysis 2 - Partial paralysis 3 - Complete paralysis
A) Motor function - left arm **B) Motor function - right arm**	0 - No drift 1 - Drift in 5 s 2 - Some effort against gravity; limb falls in 10 s 3 - No effort against gravity 4 - No movement
A) Motor function - left leg **B) Motor function - right leg**	0 - No drift 1 - Drift in 5 s 2 - Some effort against gravity; limb falls in 10 s 3 - No effort against gravity 4 - No movement
Ataxia	0 - Absent 1 - Present in one limb 2 - Present in two limbs
Sensory	0 - Normal 1 - Mild-to-moderate sensory loss 2 - Severe to total sensory loss
Language	0 - No aphasia; normal 1 - Mild-to-moderate aphasia 2 - Severe aphasia 3 - Mute, global aphasia
Dysarthria	0 - Normal 1 - Mild-to-moderate dysarthria 2 - Severe dysarthria
Extinction and Neglect	0 - No abnormality 1 - Visual, tactile, auditory, spatial, or personal inattention or extinction (1 sensory modality) 2 - Profound hemi-inattention or extinction to more than one modality

IMMEDIATE MANAGEMENT: ABC; Cardiac monitor (> 24 h); IV line; O2 (if $SaO_2 < 94\%$); Blood glucose; NPO

EXAMINATIONS: Unenhanced brain CT scan; Blood glucose; ECG; Electrolytes; Renal function; CBC; PT-aPTT; Troponin; ± Lumbar puncture (if suspicion of SAH and in the absence of bleeding on CT scan); ± EEG (rule out seizures)

DDX: Conversion; Hypertensive encephalopathy; Hypoglycemia; Complicated migraine; Seizures; Poisoning

INTRAVENOUS THROMBOLYSIS: **rtPA 0.9 mg/kg IV (max 90 mg) over 60 min** (10% of dose as a bolus over 1 min)

- ★ **NINDS rtPA Stroke Study**: < 3 h after onset of symptoms; improvement of neurological recovery at 3 months; similar mortality to that with placebo; cerebral hemorrhage in 6% of patients
  - **3 to 4.5 h of symptoms:** ★ ECASS-3; improvement of neurological recovery at 3 months
- **Post-thrombolysis**: intensive care; monitoring of neurological signs every 15-30 min for 6 h, then hourly for 24 h; Brain CT scan STAT if suspicion of intracranial hemorrhage; BP every 15-30 min for 6 h then hourly for 24 h; target BP < 180/105; repeat CT scan after 24 h

CANDIDATES FOR INTRAVENOUS THROMBOLYSIS	
< 3 h after onset of symptoms	**3 to 4.5 h after onset of symptoms**
A) Ischemic stroke with measurable neurological deficit (not minor); B) Absence of improvement of neurological deficit; C) Caution in the presence of major neurological deficit (risk of hemorrhagic transformation); D) Absence of SAH; E) Absence of head injury or stroke < 3 months; F) Absence of myocardial infarction < 3 months (risk of myocardial rupture; relative contraindication); G) Absence of GI or urinary bleeding < 21 days; H) Absence of major surgery < 14 days; I) Absence of noncompressible arterial puncture < 7 days; J) Absence of history of intracranial hemorrhage; K) Absence of CNS neoplasm / AVM / intracranial aneurysm; L) Absence of recent intracranial or spinal surgery; M) BP < 185/110; N) Absence of active internal bleeding; O) INR < 1.7; P) DOAC: normal sensitive detection test or last dose > 48 h (with normal renal function); Q) Normal aPTT if heparin received < 48 h; R) Platelet count > 100,000 mm3; S) Blood glucose > 2.7 mmol/L; T) Absence of seizures with residual neurological impairment; U) Brain CT scan: absence of multilobar infarction (1/3 of a cerebral hemisphere)	Same criteria as for thrombolysis < 3 h of symptoms + **Exclusion criteria:** a) > 80 years b) Oral anticoagulants c) NIHSS > 25 d) History of stroke + DM e) Ischemic lesion > 1/3 of the middle cerebral artery territory

INTRAARTERIAL REVASCULARIZATION

- ★ **MR CLEAN**: stroke < 6 h + proximal occlusion in the anterior cerebral circulation; 89% treated with IV tPA before randomization; intraarterial thrombolysis and/or mechanical thrombectomy versus usual care; benefit on the functional outcomes
- ★ **ESCAPE**: stroke < 12 h + proximal intracranial occlusion in the anterior circulation; early thrombectomy associated with improved functional outcome and ↘ mortality

MANAGEMENT OF BP

- **BP > 220/120 mmHg**: 10-15% ↘ BP for 24 h (Nicardipine; Labetalol)
- **Thrombolysis considered**: target BP < 185/110
  - Labetalol 10-20 mg IV x 1-2 min (can be repeated once)
  - Nicardipine: 5 mg/h (titrate every 5-10 min up to 15 mg/h; when target BP has been achieved → 3 mg/h infusion)
- **Post-thrombolysis**: Labetalol 10 mg IV x 1-2 min (then every 10-20 min; max 300 mg) or Labetalol 10 mg IV then 2-8 mg/min infusion or Nicardipine (as above)
- **Post-stroke (long-term)**: target BP < 140/90 (ACE inhibitors and/or diuretics); resume antihypertensives 24 h after stroke

ASA: 325 mg in < 48 h (> 24 h in the case of thrombolysed stroke); benefit on the morbidity - mortality

OTHER TREATMENTS: **A)** Thromboprophylaxis / sequential compression device; **B)** Detection of dysphagia (water swallow test); **C)** Target normothermia and normoxemia; **D)** Nutritional support; **E)** Insulin if blood glucose > 10.3 mmol/L (avoid hypoglycemia); **F)** Rehabilitation

SECONDARY PREVENTION

RISK FACTORS: ▸▸| Chapter 9; Treatment of HTN (from 24 h); Smoking cessation; Treatment of dyslipidemia (★ SPARCL); Treatment of DM; Moderate alcohol intake; Regular moderate physical exercise; Healthy weight; Balanced diet; Treat OSAHS

ANTIPLATELET THERAPY: indicated in a context of noncardioembolic TIA or ischemic stroke; ASA (50 to 325 mg daily) or ASA 25 mg / Dipyridamole 200 mg bid or Clopidogrel 75 mg daily

- **Evidence:** similar outcomes with Clopidogrel versus ASA / Dipyridamole (★ PRoFESS); no benefit of long-term combination of Clopidogrel and ASA (★ MATCH); ↘ adverse events with ASA / Dipyridamole versus ASA (★ ESPS-2; ★ ESPRIT)

ATRIAL FIBRILLATION: Warfarin (★ EAFT) or DOAC for secondary prevention

- **Initiation of A/C in acute stroke**: according to the severity of the stroke (risk of hemorrhagic transformation); anticoagulant therapy initiated < 14 days in ★ EAFT; wait 72 h for small stroke or 1 week for moderate stroke or 2 weeks for large stroke; no benefit of Heparin bridge
- **WATCHMAN**: LAA occlusion device; ★ PROTECT AF (noninferior to warfarin); consider when anticoagulation is contraindicated

LVEF ≤ 35 %: no evidence in support of warfarin for secondary prevention; Warfarin or ASA or Clopidogrel or ASA / Dipyridamole

RHEUMATIC MITRAL STENOSIS: Warfarin

NONRHEUMATIC VALVULAR HEART DISEASE: Aortic or mitral valve disease or mitral annular calcification or MVP; Antiplatelet therapy (IIb; C)

PFO: controversial subject; ▸▸| Chapter 7 - Congenital heart disease

THROMBOPHILIA: associated with venous >>> arterial thromboses; anticoagulation if concomitant DVT; Antiplatelet therapy or anticoagulation in the absence of DVT or an identifiable cause of stroke

- **Antiphospholipid syndrome**: anticoagulation indicated

CAROTID ARTERY REVASCULARIZATION

SYMPTOMATIC CAROTID ARTERY STENOSIS: benefit of surgical revascularization compared to medical treatment (★ NASCET; ★ ECST; ★ VACS); NNT = 6

ASYMPTOMATIC CAROTID ARTERY STENOSIS: benefit of surgical revascularization in selected patients (★ ACAS and ★ ACST; studies conducted prior to the introduction of modern medical treatment); NNT = 33

ANGIOPLASTY-STENTING VERSUS ENDARTERECTOMY: **comparable long-term outcomes** (★ CREST; ★ SAPPHIRE)

- **Angioplasty-Stenting**: increased risk of periprocedural stroke compared to endarterectomy (particularly in patients > 70 years)
- **Prefer angioplasty-stenting**: anatomical / technical considerations (post-radiation; post-surgical; obesity; hostile neck; stenosis at different level); high operative risk - severe comoborbidities
- **Dual antiplatelet therapy**: 4 weeks

REVASCULARIZATION IN THE PRESENCE OF MULTIPLE COMORBIDITIES: little evidence in favor of surgical or endovascular revascularization (NYHA III-IV; CCS III-IV; CAD ≥ 2 vessels or LMCA; LVEF ≤ 30%; recent myocardial infarction; severe lung disease; advanced CRF)

	SYMPTOMATIC (< 6 MONTHS)		ASYMPTOMATIC
	Carotid artery stenosis: 50-69% (angiography)	**Carotid artery stenosis: 70-99% (noninvasive imaging)**	**Carotid artery stenosis > 70%**
Endarterectomy	**I; B**	**I; A**	**IIa; A**
	To be performed within 14 days of the neurological event unless contraindicated (IIa; B)		Mortality - perioperative stroke < 3% Life expectancy > 5 years
	Mortality - perioperative stroke < 6% Life expectancy > 5 years		
Angioplasty-Stenting	Alternative to surgery: I; B	Alternative to surgery: I; B	IIb; B (controversial)
	Mortality - perioperative stroke < 5%		

INTRACRANIAL HEMORRHAGE

MANAGEMENT: Intensive care; Neurosurgical assessment; Target normothermia; Target blood glucose < 10.3 mmol/L; Thromboprophylaxis (sequential compression device; IVC filter PRN); Phenytoin in the presence of seizures; ± Continuous EEG monitoring

ANTICOAGULATION: Discontinue anticoagulation and antiplatelet therapy for more than 1-2 weeks and subsequently reassess the indication; weigh up the thromboembolic risk against the bleeding risk (high in cortical stroke secondary to amyloid angiopathy)

- **Reverse Warfarin**: **prothrombin complex concentrate** (Octaplex; Beriplex; Cofact; Proplex); complex of factors II - VII - IX - X; Target INR < 1.4
  - **Vitamin K**: 10 mg IV (max 1 mg/min)
  - **Fresh frozen plasma**: 8 units when prothrombin complex concentrate is not available

BLOOD PRESSURE: treat if sBP > 180 mmHg in the absence of intracranial hypertension; target BP < 160/90 (labetalol; nicardipine; esmolol; enalapril; hydralazine; nitroprusside; TNT)

CONTROL OF INTRACRANIAL HYPERTENSION: target cerebral perfusion pressure > 60 mmHg (MAP - ICP) and ICP < 20-25 mmHg; raise head of bed by 30°; analgesia; control of BP (target SBP < 180 mmHg and MAP < 130 mmHg, while maintaining adequate cerebral perfusion pressure); ventriculostomy (external CSF drainage); IV mannitol (target plasma osmolality: 300-310 mOsmol/kg); sedation; hyperventilation ($PaCO_2$: 30-35 mmHg); neuromuscular blockade; surgical evacuation of hematoma; barbiturate-induced coma

8.8/ PULMONARY EMBOLISM

RISK FACTORS: Age; Personal or family history of pulmonary embolism; Cancer; Trauma; Surgery; Immobilization; Pregnancy; Hormonal therapy; Oral contraceptive; Nephrotic syndrome; Chemotherapy

- **Thrombophilia**: Homozygous factor V Leiden; Homozygous prothrombin G20210A; Protein C deficiency; Protein S deficiency; Antiphospholipid syndrome / Lupus anticoagulant

PRESENTATION: Dyspnea; Pleuritic pain; Retrosternal chest pain; Cough; Hemoptysis; Paradoxical embolism; Syncope; Sudden death - Pulseless electrical activity

CLINICAL FEATURES: Tachypnea; Tachycardia; ± Shock; ± Cyanosis (R→ L shunt via PFO); ↘ SaO_2; Low-grade fever; JVD; Left parasternal heave; ↗ P2; TR murmur; right S3 or S4; Pleural friction rub (pulmonary infarction); signs of DVT in leg (edema; erythema; heat; pain; difference between legs)

D-DIMERS: **very sensitive but not specific**

ECG: Sinus tachycardia; S1Q3T3; *de novo* RBBB; T wave inversion (V1 to V4; inferior leads); Q in III and aVF; Qr in V1; ST depression or ST elevation in V1-V4; right axis deviation; AF / Flutter

CXR: PA dilatation; Atelectasis; Elevation of the diaphragm; Pleural effusion

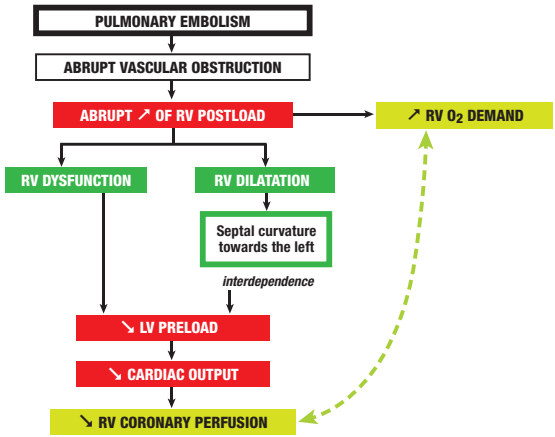
- **Westermark sign:** Segmental oligemia secondary to proximal arterial occlusion
- **Hampton hump**: Triangular hyperdensity adherent to the pleura secondary to pulmonary infarction (consolidation with hemorrhage)

TTE: RV dilatation (↗ acute afterload); RV hypokinesia; PHT (non-preconditioned RV is unable to genereate a mPAP > 40 mmHg); TR; shunt via PFO; thrombus-in-transit visible in right chambers / PA; septal curvature towards the LV; dilated and noncompliant IVC

- **McConnell's sign: hypokinesis of basal / mid RV free wall (preserved apex contractility)** +

LEG ULTRASOUND: look for ↘ vein compressibility

CONSEQUENCES OF PULMONARY EMBOLISM

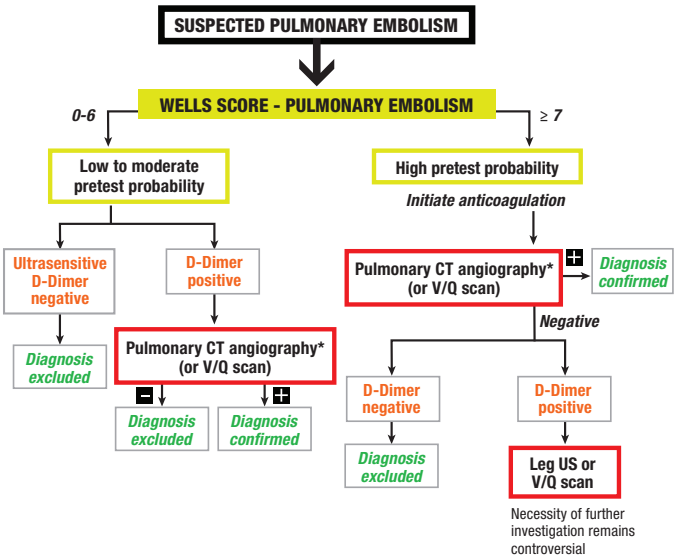


ASSESSMENT

WELLS CRITERIA – PRETEST PROBABILITY – DEEP VEIN THROMBOSIS		
Active cancer	1 point	• **0 point**: low pretest probability • **1-2 points:** moderate pretest probability • **≥ 3 points:** high pretest probability
Paralysis or recent cast immobilization	1 point	
Bedridden > 3 days or surgery < 4 weeks	1 point	
Local vein tenderness	1 point	
Swelling of entire leg	1 point	
Difference between calves > 3 cm	1 point	
Pitting edema	1 point	
Superficial collateral vein	1 point	
Alternative diagnosis at least as likely	- 2 points	

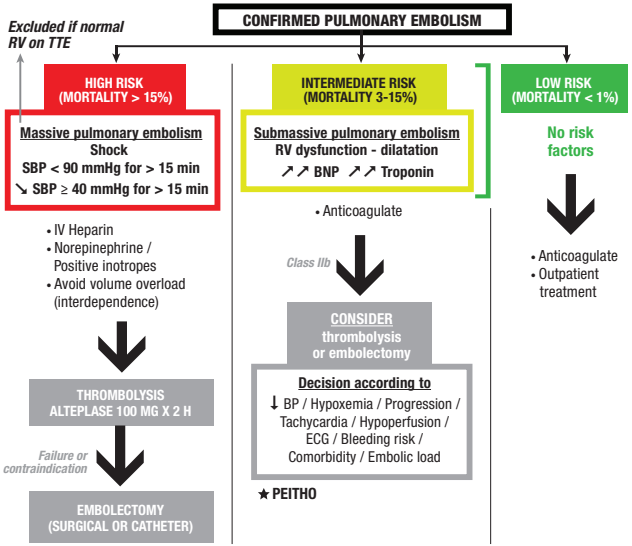
WELLS CRITERIA – PRETEST PROBABILITY – PULMONARY EMBOLISM		
Signs or symptoms of DVT	3 points	• **0-1 point**: low pretest probability (10%) • **2-6 points**: moderate pretest probability (30%) • **≥ 7 points**: high pretest probability (65%)
Alternative diagnosis is less likely	3 points	
HR > 100 bpm	1.5 points	
Immobilization or surgery < 4 weeks	1.5 points	
History of DVT or pulmonary embolism	1.5 points	
Hemoptysis	1 point	
Cancer (< 6 months or metastasis)	1 point	

Wells PS, Anderson DR, Bormanis J, et al, Lancet 1997; 350:1795
van Belle A, et al. JAMA 2006; 295:172



*** Interpret according to:**
A) Pretest probability
B) Site of thrombus (main PA or lobar or segmental versus subsegmental PA)

MANAGEMENT



★ **PEITHO**: PE with RV dysfunction and ↗ Troponin; Tenectaplase + Heparin vs Heparin; ↘ Haemodynamic decompensation; similar all-cause 7-day mortality; ↗ intracranial bleeding; ↗ major hemorrhage

Unfractionated heparin	• IV bolus: 80 IU/kg • IV infusion: 18 IU/kg/h (target aPTT 1.5-2.5 x control or 60-80 s)	
Enoxaparin	• 1 mg/kg SC bid or 1.5 mg/kg qd	**LMWH** • Better bioavailability • More predictable effect • Avoid if GFR < 30 mL/min
Dalteparin	• 100 IU/kg SC bid or 200 IU/kg qd	
Tinzaparin	• 175 IU/kg SC bid	
Fondaparinux	• < 50 kg: 5 mg SC qd • 50-100 kg: 7.5 mg SC qd • > 100 kg: 10 mg SC qd	• Indirect Xa inhibitor • Avoid if GFR < 30 mL/min
History of HIT	Argatroban or Bivalirudin or Lepirudin or Danaparoid	

WARFARIN: **anticoagulant effect in 5 days**

› **Initially procoagulant effect:** due to ↘ proteins C and S

› **Overlapping of warfarin with Heparin ≥ 5 days (and ≥ 24 h with INR ≥ 2.0)**

Provocated pulmonary embolism or proximal DVT (secondary to surgery; trauma; pregnancy; hormonal therapy)	Thromboembolism and active cancer	Idiopathic or recurrent pulmonary embolism (or proximal DVT)
Anticoagulation x 3 months	LMWH (★ CLOT) Continue in the presence of active cancer (warfarin as alternative)	Anticoagulation x ≥ 3 months and consider long-term treatment (according to balance between the risks of recurrence and bleeding)

DOAC IN ACUTE PHASE OF THROMBOEMBOLIC DISEASE: ★ EINSTEIN (Rivaroxaban 15 mg bid x 3 weeks then 20 mg qd); ★ AMPLIFY (Apixaban 10 mg bid x 7 days then 5 mg bid)

SECONDARY PREVENTION (after acute phase): Options → **A)** Warfarin; **B)** Rivaroxaban 20 mg qd (★ EINSTEIN-extension); **C)** Apixaban 2.5 mg bid (★ AMPLIFY-extension); **D)** Dabigatran 150 mg bid (★ RE-SONATE and ★ RE-MEDY); **E)** ASA 100 mg qd (★ ASPIRE and ★ WARFASA)

IVC FILTER: Indications → **A)** Bleeding / Contraindication to anticoagulation; **B)** Recurrent pulmonary embolism despite treatment (in the presence of a proximal thrombosis)

- ↘ Pulmonary embolism recurrence rate; ↗ DVT recurrence rate
- **Complications:** access site complication; recurrent DVT; IVC thrombosis; IVC perforation; migration; post-thrombotic syndrome
- Resume anticoagulation and **remove** the filter as soon as possible

INTRAVENOUS THROMBOLYSIS: ↘ mortality in massive pulmonary embolism

- **Alteplase 100 mg IV x 2 h** (without heparin); resume heparin without bolus at the end of thrombolysis if aPTT ≤ 80 s

CATHETER-ASSISTED THROMBUS REMOVAL

- **Indications**: Hemodynamic instability with → **A)** Contraindication to thrombolysis or **B)** Failure of thrombolysis (rescue)
  - **Consider surgery** in the presence of mobile thrombus-in-transit in right chambers or thrombus-in-transit in PFO

LOCAL CATHETER THROMBOLYSIS FOR DVT: A) Extensive ilio-femoral thrombosis with low bleeding risk (including *phlegmasia cerulea dolens*); **B)** Progression of thrombus despite treatment; **C)** Extensive upper extremity DVT (subclavian and axillary veins)

- **Benefit:** ↘ risk of postthrombotic syndrome
- **Pharmacomechanical approach**: local thrombolysis combined with catheter thrombectomy ± balloon venoplasty (± stent)

UPPER EXTREMITY DVT: Risk factors → central catheter; pacemaker; thoracic outlet syndrome (Paget-Schroetter disease); Cancer

- Risk of complications in the case of proximal DVT (starting at axillary vein)
- **Risk of PE**: 10 %
- **Anticoagulation**: ≥ 3 months
  - It is acceptable to observe upper extremity DVT **distal to the axillary vein**

POSTTHROMBOTIC SYNDROME: varicosities; hyperpigmentation; ulcers

- **Compression stockings**: 30-40 mmHg
- Consider angioplasty ± stenting in the presence of iliac vein obstruction

THROMBOPROPHYLAXIS IN MEDICALLY HOSPITALIZED PATIENTS

- **Unfractionated heparin:** 5000 IU SC bid or tid
- **LMWH**: Enoxaparin 40 mg SC qd or Dalteparin 5000 U SC qd
- **Fondaparinux:** 2.5 mg SC qd (useful in patients with a history of HIT)
- **Intermittent pneumatic compression**: contraindication to anticoagulants or multiple risk factors (with anticoagulant)

8.9/ HEPARIN-INDUCED THROMBOCYTOPENIA (HIT)

TYPE 1 HIT: Benign form

TYPE 2 HEPARIN-INDUCED THROMBOCYTOPENIA

Immune form (IgG)

PATHOPHYSIOLOGY: Antibody directed against neoantigens on protein PF4 (protein released by activated platelets)

› Neoantigens are exposed following binding of PF4 with heparin → IgG binds simultaneously to the heparin-PF4 complex and to platelet Fc receptors → platelet activation with release of prothrombotic molecules → platelet consumption + intense thrombin production → multiple thromboses (venous or arterial)

5-10 days post-exposure to heparin (or earlier in the case of re-exposure < 3 months)

↘ > 50% of platelets (compared to baseline count) or thrombosis beginning 5-10 days after the start of heparin

4 T SCORE			
	2 POINTS	**1 POINT**	**0 POINT**
Thrombo-cytopenia	> 50% decrease in platelet count and nadir ≥ 20,000/µL and no surgery in past 3 days	• > 50% decrease in platelet count and surgery in past 3 days or • 30-50% decrease in platelet count or • Nadir 10,000-20,000/µL	• < 30% decrease in platelet count or • Nadir < 10,000/µL
"Timing" (post-exposure)	Day 5 to Day 10 (or ≤ 1 day if prior heparin exposure within 30 days)	Uncertain interval (but probably between Day 5 and Day 10) or after Day 10 (or ≤ 1 day if prior heparin exposure within 30-100 days)	Decrease in platelet count ≤ Day 4 (no other heparin therapy during past 100 days)
Thrombosis	Confirmed new thrombosis; Skin necrosis at injection site; Anaphylactoid reaction to IV heparin bolus	Recurrent venous thrombosis while on anticoagulant therapy or suspected thrombosis or nonnecrotic skin lesions at injection site	None
oTher causes	No alternative cause to explain thrombocytopenia	Possible alternative cause	Probable alternative cause (recent surgery; bacteremia; chemotherapy; drugs…)

6-8 points: high probability (34%)
4-5 points: intermediate probability (11%)
0-3 points: low probability (0.9%)

Lo GK, Warkentin TE, Sigouin CS et al. J Thromb Haemost. 2006; 4: 759-65.

DIAGNOSTIC WORK-UP: to be performed in the case of intermediate to high probability (4 T score)

- **ELISA assay of anti-PF4 antibodies** (excellent NPV but low PPV)
- **Serotonin-release assay** (platelets containing labeled serotonin placed in contact with the patient's plasma and heparin); gold standard diagnostic test

PREVENTION: CBC every 2-3 days (starting on Day 5 of heparin therapy)

MANAGEMENT OF TYPE 2 HIT

1) Stop all forms of heparin
2) Argatroban or Bivalirudin or Fondaparinux or Danaparoid
3) Initiate Warfarin **once the thrombocytopenia has resolved** (with IV co-administration of a direct thrombin inhibitor; overlapping for ≥ 5 days; discontinue after achieving therapeutic INR for 2 days); anticoagulation ≥ 3 months if confirmed thrombosis
   - If the patient is treated with Warfarin at the time of HIT: reverse with vitamin K

8.10/ PULMONARY HYPERTENSION

PHT	GROUP 1–3–4–5 PHT	POSTCAPILLARY (GROUP 2)
mPAP ≥ 25 mmHg	mPAP ≥ 25 mmHg Wedge ≤ 15 mmHg	mPAP ≥ 25 mmHg and Wedge > 15 mmHg
		Isolated postcapillary: dPAP - Mean Wedge < 7 mmHg and/or PVR ≤ 3 WU
		With precapillary component: dPAP - Mean Wedge ≥ 7 mmHg and/or PVR > 3 WU

ETIOLOGIES

	mPAP ≥ 25 mmHg; Wedge ≤ 15 mmHg; PVR ≥ 3 WU
Group 1: Pulmonary arterial hypertension (PAH)	• **Idiopathic PAH** • **Heritable PAH** - BMPR2; ALK1; Endoglin; SMAD9; CAV1; KCNK3 mutation - Hereditary hemorrhagic telangiectasia (Osler-Weber-Rendu) • **PAH secondary to drugs - toxins** (Anorectics; Cocaine; Amphetamines) • **PAH associated with** - **Collagen diseases** › Scleroderma - CREST; SLE; Mixed connective tissue disease; RA; Sjögren; Dermatomyositis - **HIV** - **Portal hypertension** (Cirrhosis) › Liver transplantation contraindicated if mPAP ≥ 35 mmHg or PVR > 250 dyn x s / cm^5 - **Congenital heart disease** (Shunt) › VSD; Patent ductus arteriosus; ASD; Anomalous pulmonary venous return; AV canal defect; Complex congenital heart disease - **Schistosomiasis**

Group 1`	• **Pulmonary veno-occlusive disease and pulmonary capillary hemangiomatosis** - Similar presentation to that of PAH - Suspect in the presence of pulmonary edema following administration of pulmonary artery vasodilators - Characteristic changes on pulmonary HDCT (subpleural thickened septal lines; centrilobular ground-glass opacities; lymphadenopathy)
Group 2: PHT secondary to left heart disease	**mPAP ≥ 25 mmHg; Wedge > 15 mmHg** • LV systolic dysfunction • LV diastolic dysfunction • Left-sided valvular heart disease • Pulmonary veins stenosis
Group 3: Pulmonary hypertension secondary to lung disease	• COPD • Interstitial lung disease • Mixed lung disease • Sleep-disordered breathing • Alveolar hypoventilation • High altitude
Group 4	• Thromboembolic pulmonary hypertension
Group 5: Uncertain mechanism	• **Hematological disease**: Myeloproliferative disease (Polycythemia vera; Essential thrombocytosis; CML); Splenectomy; Chronic hemolytic anemia (Sickle-cell anemia; Hereditary spherocytosis; Homozygous beta-thalassemia) • **Systemic disease**: Sarcoidosis; Langerhans cell histiocytosis; Lymphangioleiomyomatosis; Neurofibromatosis; Vasculitis • **Metabolic disease**: Glycogen storage disease; Gaucher; Thyroid disease • **Other**: Neoplastic obstruction; Fibrosing mediastinitis; Dialysis
Reversible causes of PHT secondary to ↗ transpulmonary blood flow Exercise; Anemia; Pregnancy; Sepsis; Hyperthyroidism; Volume overload	

ASSESSMENT

PRESENTATION: Dyspnea on exertion; Fatigue; Retrosternal chest pain; Syncope; Palpitations; Leg edema; Ortner's syndrome (recurrent laryngeal nerve compression by dilated PA); Hemoptysis

CLINICAL FEATURES: Hypotension; Cold extremities; ± Cyanosis; JVD (↗ A wave; ↗ V wave); left parasternal heave; Pulmonary artery palpable in left second intercostal space; ↗ P2; Ejection click / Systolic ejection murmur at pulmonary site; Holosystolic murmur (TR; ↗ on inspiration); PR murmur (Graham-Steel); Right S3 and/or S4; Pulsatile liver; Anasarca

› Look for signs of collagen disease (sclerodactyly; arthritis; telangiectasias; Raynaud; rash) and liver disease (spider naevi; testicular atrophy; palmar erythema); look for clubbing

ASSESSMENTS: HIV; ANA; RF; LFTs (± liver US); BNP; TSH; Thrombophilia screening (group 4)

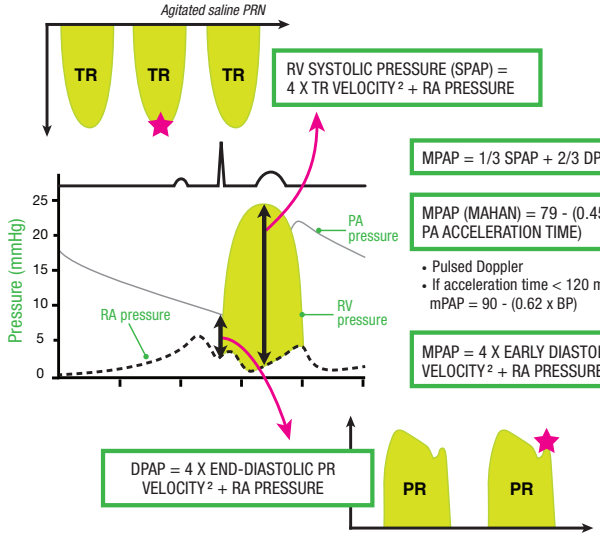
ECG: RAH; RVH; R axis deviation; T wave inversion in R precordial leads; RBBB; Atrial arrhythmias

CXR: central PA dilatation; RA-RV dilatation; pruning (loss) of the peripheral blood vessels (oligemia)

TTE: ↗ PAP; RA and RV dilatation (RV / LV basal diameter ratio > 1.0); PA dilatation (> 25 mm); RVH; RV dysfunction (RIMP - S' - TAPSE - Strain); Curvature of the septum towards LV; Small left chambers; TR; Pericardial effusion; Look for shunt; Look for cause of PHT due to heart disease

› **Screening**: **A)** Scleroderma: annually (+ DLCO / biomarkers); **B)** Sickle-cell anemia: annually

TTE (CONTINUED)



CARDIAC MRI: More favorable prognostic factors → Ejection volume > 25 mL/m² or RV end-diastolic volume < 84 mL/m² or LV end-diastolic volume > 40 mL/m²

PULMONARY ASSESSMENT: CXR; PFTs; Pulmonary high-resolution CT; Arterial blood gases; V/Q scan (± CT angiography / pulmonary angiography); Nocturnal saturometry / Polysomnography

- **PFTs**: PAH associated with mild-to-moderate ↘ lung volumes and ↘ DLCO (40 to 80% of predicted)
- **Rule out thromboembolic PHT (Group 4) in all patients by V/Q scan** +

RIGHT/LEFT CATHETERIZATION

- **Look for a shunt** (oximetry run)
- **Wedge pressure** (end of expiration) ± LVEDP; 500 mL bolus PRN to reveal diastolic dysfunction
- **Cardiac output**: Thermodilution (in the absence of significant TR or low output state or shunt) or Fick
- **PVR (WU)** = **mPAP - Wedge / Cardiac output**
- **Diastolic pressure gradient** = **dPAP - Mean Wedge**
- **Vasoreactivity test** (Idiopathic PAH; Heritable PAH; Drug-induced PAH)
  - **Positive**: **absolute ↘ of mPAP ≥ 10 mmHg (to mPAP < 40 mmHg) in the absence of ↘ cardiac output** +

INHALED NO (FIRST LINE)	IV EPOPROSTENOL	IV ADENOSINE
10 to 20 ppm	2 - 12 ng/kg/min	50 to 350 µg/kg/min

- **Hepatic venous pressure gradient** = **Wedged hepatic venous pressure - IVC pressure;** normal value between 1-5 mmHg (≥ 10 mmHg → portal hypertension / cirrhosis)

MONITORING OF FUNCTIONAL CAPACITY: WHO functional class (equivalent to NYHA); 6MWT; Stress test; Cardiopulmonary test / VO_2 max

MANAGEMENT

O_2 (target: SaO_2 > 90% and PaO_2 > 60 mmHg)

AVOID PREGNANCY

REHABILITATION / AEROBIC EXERCISE PROGRAM

AVOID HIGH ALTITUDE; O_2 in plane when SaO_2 < 92% (or PaO_2 < 60 mmHg)

VACCINATION (Influenza - Pneumococcus)

SODIUM RESTRICTION (< 2.4 g/day) in the presence of volume overload

DIURETICS for volume overload

DIGOXIN (right heart failure or atrial tachyarrhythmias)

DRUG THERAPY FOR GROUP 1 PAH		
Anticoagulation	**Warfarin** Target INR: 2.0 to 2.5	Consider in idiopathic PAH or Heritable PAH or PAH due to anorexigens (class IIb recommendation)
Calcium channel blocking agents	**Nifedipine** (120 - 240 mg) **Diltiazem** (720 - 960 mg) **Amlodipine** (20 - 30 mg PO)	In patients with idiopathic PAH, Heritable PAH or drug induced PAH and positive vasoreactivity test Continue if WHO functional class 1 to 2/4 with marked hemodynamic improvement
Prostanoids (prostacyclins) **Vasodilators** **Antiproliferative agents**	**Epoprostenol** 2 ng/kg/min IV (target 25 - 40 ng/kg/min)	**Only agent demonstrated to ↘ mortality in IPAH** (★ Primary Pulmonary Hypertension Study Group) Need for intravenous administration (risk of local infection and catheter obstruction / sepsis)
	Treprostinil (SC or IV or inhaled) • s/c: 1-2 to 20 - 80 ng/kg/min • Inhaled: 30 - 45 µg qid	Associated with infusion site pain
	Iloprost aerosol 2.5 - 5 µg (6-9 per day)	Associated with flushing and jaw pain
Prostacyclin IP receptor agonist	**Selexipag** 200-1600 µg PO bid	Headache; Diarrhea; Nausea; Flushing
Endothelin receptor antagonist **Vasodilator**	**Ambrisentan** 2.5 - 5 - 10 mg PO qd	Adverse effects: liver function test abnormalities; edema
	Bosentan 125 mg PO bid	Monitor liver function monthly
	Macitentan 3 or 10 mg PO qd	Can cause anemia
Phospho-diesterase-5 inhibitor **↗ NO**	**Sildenafil** 20 mg PO tid	Associated with headache, flushing, epistaxis **Do not combine with soluble guanylatecyclase stimulator**
	Tadalafil 2.5 - 10 - 20 - 40 mg PO qd	
Soluble guanylate cyclase stimulator **↗ NO**	**Riociguat** 2.5 mg PO tid	Approved for group 1 PAH (★ PATENT) and thromboembolic PHT (★ CHEST) Risk of syncope **Do not combine with PDE–5 inhibitor**

BALLOON ATRIAL SEPTOSTOMY FOR RA-RV DECOMPRESSION: creation of a R → L shunt; ↘ RV filling pressures; improvement of LV filling; ↗ cardiac output (**at the cost of hypoxemia**)

› **Indications**: Severe PAH with treatment-refractory right heart failure (including inotropes) or recurrent syncope or bridge to transplant

LUNG TRANSPLANT: Progressive treatment-refractory PAH; WHO functional class 3-4/4

› **5-year survival:** 52-75%; risk of bronchiolitis obliterans - rejection - opportunistic infections

GROUP 2 PHT: left heart disease causing **venous PHT with passive retrograde transmission of increased pressure**

› **Wedge > 15 mmHg; Diastolic pressure gradient < 7 mmHg (dPAP - Mean Wedge)** +

› May be associated with pulmonary hemosiderosis (leakage of RBC from capillaries) with formation of fibrosis

› **Pulmonary artery vasodilators: risk of pulmonary edema in the presence of ↗ LV filling pressures** +

- **PAH-approved therapies are not recommended in group 2 PHT**
- **PDE-5 inhibitors / Macitentan**: awaiting the results of the ★ SIl-HF and ★ MELODY-1

› **Postcapillary PHT with precapillary component**: **development of arterial PHT with ↗ PVR as mechanism of adaptation to pulmonary edema**

- **Active component**: ↗ pulmonary artery vasomotor tone and/or fixed obstructive arterial structural remodeling
- **Diastolic pressure gradient ≥ 7 mmHg (dPAP - Mean Wedge)** +
- **Consider pulmonary artery vasodilators** on an individual basis by the expert PH centre

GROUP 4 PHT: organized thrombus associated with the arterial wall with lobar or segmental or subsegmental perfusion abnormality

› Pulmonary arteriopathy superimposed (similar to idiopathic PAH)

› **V/Q scan:** screening test of choice

- CT pulmonary angiography / Conventional pulmonary angiography for confirmation

› **Thromboendarterectomy:** treatment of choice (deep hypothermia circulatory arrest)

- Consider balloon pulmonary angioplasty if technically non-operable

› **Anticoagulation** for life

› **Consider pulmonary artery vasodilators** when thromboendarterectomy is impossible or gives mixed results; prefer Riociguat (beneficial in ★ CHEST)

PAH ASSOCIATED WITH CONGENITAL HEART DISEASE (SHUNT)

EINSENMENGER	PAH WITH L→R SHUNT	PAH WITH SMALL SEPTAL DEFECT	POST-CORRECTION PAH
• Large defect • Severely ↗ PRV • Reversed shunt (or bidirectional) • Cyanosis; Erythrocytosis; multisystem features	• Moderate-to-large defect • No cyanosis at rest • Do not operate if PVR > 4.6 WU (or indexed PVR > 8 WU/m²)	• VSD < 1 cm • ASD < 2 cm • ↗ PVR disproportional to congenital anomaly • Similar profile to idiopathic PAH	• PAH despite absence of a residual defect

› **Shunt distal to the tricuspid valve** (VSD; patent ductus arteriosus; truncus arteriosus) subjects pulmonary arteries to much higher pressure stress than pre-tricuspid shunt

PREOPERATIVE ASSESSMENT - NON-CARDIAC SURGERY
Emergent surgery
Yes
Proceed to surgery
No
Active heart disease
Yes
Stabilize condition
• Unstable coronary disease
• Decompensated heart failure
• Significant arrhythmia
• Severe valvular disease
No
Perioperative risk of MACE
• Revised Cardiac Risk Index And/or
• American college of Surgeons risk calculator www.surgicalriskcalculator.com
Low risk (< 1%)
And/or
Surgical procedure with a low risk of MACE
No further testing
Proceed to surgery
Elevated risk (> 1%)
> 10 METs
No further testing
Proceed to surgery
4-10 METs
No further testing
Proceed to surgery
< 4 METs or unknown functional capacity
Will further testing impact decision making or perioperative care?
No
No further testing
Yes
Non-invasive stress test
Rule out severe CAD with an impact on prognosis (± coronary revascularization)
Perioperative BB (started several days pre-op with adequate titration)
1) Patient already treated with BB
2) Intermediate- or high-risk non-invasive stress test (IIb)
3) ≥ 3 RCRI risk factors (IIb)
4) Initiate in patients with a compelling long term-indication (IIb)

EVALUATION OF FUNCTIONAL CAPACITY

1 MET

- Eating; dressing; going to the toilet
- Walking indoors
- Walking 1-2 blocks (3.2-4.8 kph)
- Light housework (washing dishes; dusting)

4 METs

- **Climbing one flight of stairs**
- Walking at 6.4 kph
- Running a short distance
- Heavy housework (scrubbing floors; moving furniture)
- Golf - Bowling - Dancing - Doubles tennis - Playing ball
- Swimming - Singles tennis - Skiing - Basketball

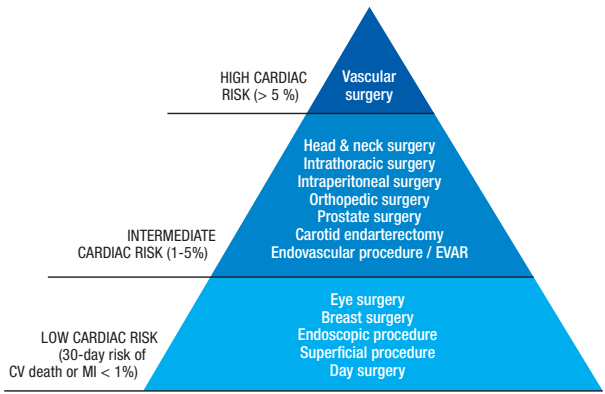
10 METs

REVISED CARDIAC RISK INDEX (RCRI) DURING NONCARDIAC SURGERY

1) History of CAD 2) History of heart failure 3) History of cerebrovascular disease 4) Insulin-treated DM 5) Pre-op Creatinine > 2 mg/dL (> 176 mmol/L) 6) Intrathoracic or intraperitoneal or vascular surgery	**Risk of cardiac events** (MI; pulmonary edema; VF; cardiac arrest; complete heart block) 0 point = low risk (0.5%) 1 point = moderate risk (1.3%) 2 points = moderate risk (3.6%) ≥ 3 points = high risk (9.1%)

Lee TH, Marcantonio ER, Mangione CM. Circulation 1999; 100; 1043-1049

CARDIAC RISK ASSOCIATED WITH SURGERY



NONINVASIVE STRATIFICATION

OBJECTIVE: to exclude the presence of severe CAD with an impact on prognosis and which would require revascularization, regardless of the type of surgery

PREOPERATIVE REVASCULARIZATION: **no benefit on perioperative events,** even in the presence of significant ischemia on noninvasive stratification (★ CARP; ★ DECREASE-V)

INDICATIONS FOR PREOPERATIVE REVASCULARIZATION: identical to stable CAD or unstable angina or NSTEMI or STEMI (▸▸| Chapter 2 - CAD) +

PERIOPERATIVE BETA-BLOCKERS AND STATINS

BB - INDICATIONS: **1)** Patient already treated with BB (Class I recommendation); **2)** Intermediate- or high-risk non-invasive stress test (IIb); **3)** ≥ 3 RCRI risk factors (IIb); **4)** Initiate in patients with a compelling long term indication (IIb)

BB - MODALITIES OF USE: Start BB therapy several days preoperatively; titrate the dose targeting a resting HR of 60-80 bpm; avoid hypotension

› ★ **POISE**: High-dose Metroprolol succinate started **2-4 h preoperatively** versus placebo; ↘ primary outcomes (cardiovascular mortality; MI) but ↗ all-cause mortality and ↗ stroke

STATINS - INDICATIONS: 1) Patient already on statin (I); **2)** Initiate if undergoing vascular surgery (IIa); **3)** Initiate in patients with clinical indications who are undergoing elevated-risk procedures (IIb)

PERIOPERATIVE ECG AND TROPONIN

ECG: Preoperative → CAD, arrhythmia, PAD, cerebrovascular disease or structural heart disease (except for low-risk procedures); **Post-operative** → **A)** Signs or symptoms suggestive of ischemia / MI / arrhythmia; **B)** Usefulness of routine screening in asymptomatic patient is uncertain (IIb)

POSTOPERATIVE TROPONIN: Indications → **A)** Signs or symptoms suggestive of ischemia or MI; **B)** Usefulness of routine screening in asymptomatic patient is uncertain (IIb)

DIAGNOSIS OF PERIOPERATIVE MYOCARDIAL INFARCTION: ▸▸| Chapter 2 (Definition of MI)

› **Consider type 1 myocardial infarction (rupture of fragile plaque) or type 2 (O_2 supply/ demand mismatch); Type 1 MI causes < 5% of troponin elevation postoperatively** +

PERMANENT PACEMAKER AND DEFIBRILLATOR

PACEMAKER-DEPENDENT PATIENT: Reprogram in V00 or D00 mode or apply a magnet during the operation (asynchronous stimulation)

DEFIBRILLATOR: **Temporarily** deactivate tachyarrhythmia therapies or apply a magnet during the operation

› **N.B.**: a magnet applied to a defibrillator deactivates tachyarrhythmia therapies, **but does not change the pacing mode to V00 or D00**; risk of inappropriate inhibition of pacing

SPECIFIC ENTITIES

HCM: avoid dehydration / vasodilators / hypotension / beta-agonists

SEVERE AORTIC STENOSIS

› **Asymptomatic**: complete preoperative clinical reassessment with stress test; consider AVR before elective high-risk non-cardiac surgery; monitor intravascular volume; avoid tachycardia; avoid intraoperative hypotension (treat with phenylephrine)

› **Patient refusing AVR or not a candidate or requiring urgent surgery**: operative mortality ≥ 10%; consider TAVI or balloon valvuloplasty if hemodynamically unstable

POST-PCI SURGERY AND DUAL ANTIPLATELET THERAPY

- **Post-PTCA**: wait **2-4 weeks** (then operate under ASA)
- **Post-BMS**: dual antiplatelet therapy for a minimum of **2-4 weeks** (then operate under ASA)
  - Discontinue Clopidogrel 5-7 days preoperatively
- **Post-DES**: dual antiplatelet therapy for a **strict minimum of 3 to 6 months** with new generation stents (consider bridging with IV tirofiban / eptifibatide / cangrelor if surgery required before this time) then operate under ASA

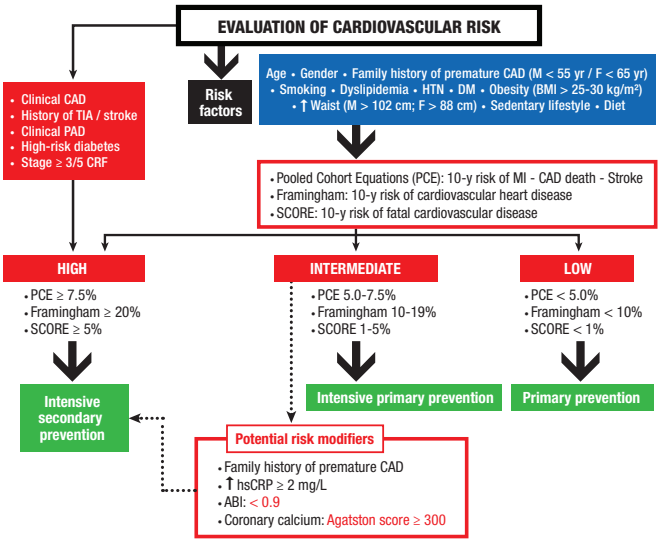
	MECHANICAL VALVE PROSTHESIS	ATRIAL FIBRILLATION	THROMBOEMBOLIC DISEASE
High thrombo-embolic risk (annual risk > 10%)	• Mitral valve prosthesis • Old generation aortic valve prosthesis (cageball; tilting-disk) • Stroke or TIA < 6 months	• CHADS 5 or 6 • Stroke or TIA < 3 months • Rheumatic disease	• Thromboembolism < 3 months • Severe thrombophilia (protein C or S or antithrombin deficiency; antiphospholipid antibodies; multiple anomalies)
	• Stop Warfarin 5 days pre-op + Bridge with IV heparin or LMWH - **Prosthetic Valve or AF** → Enoxaparin 1 mg/kg bid or Dalteparin 100 IU/kg bid; **Venous thromboembolism** → Enoxaparin 1.5 mg/kg qd or Dalteparin 200 IU/kg qd • INR on the day before surgery (vitamin K 1 mg PO if INR > 1.5) • Stop IV Heparin 4-6 h pre-op; Last dose of LMWH 24 h pre-op (Enoxaparin 1 mg/kg or Dalteparin 100 IU/kg administered 24 h pre-op) • Resume Warfarin 12-24 h post-op if adequate hemostasis • Resume Heparin (without bolus) or LMWH 48-72 h post-op depending on hemostasis • Consider IVC filter in the presence of venous thromboembolism < 4 weeks		
Moderate thromboembolic risk (annual risk 5-10%)	**Bileaflet aortic valve prosthesis with ≥ 1 risk factor:** AF • History of stroke or TIA • HTN • DM • Heart failure • > 75 years	CHADS 3 or 4 (no benefit in ★BRIDGE; mean CHADS = 2.3)	• Thromboembolism 3-12 months • Nonsevere thrombophilia: Leiden factor V or prothrombin mutation (heterozygous) • Active neoplasia
	• Case-by-case decision for heparin bridge (thromboembolic risk versus perioperative bleeding risk)		
Low thromboembolic risk (annual risk < 5%)	Bileaflet aortic valve prosthesis with no other risk factor	CHADS 0 to 2 (with no history of stroke or TIA)	Thromboembolism > 12 months (with no other risk factor)
	• Heparin bridge not recommended		

MINOR PROCEDURES: do not discontinue Warfarin for superficial skin or ophthalmic (cataract) or dental procedures (use tranexamic acid)

PERIOPERATIVE DOAC: ▶▶| Chapter 6

9.2/ PRIMARY & SECONDARY PREVENTION OF CARDIOVASCULAR DISEASE

EVALUATION OF THE RISK OF ADVERSE CARDIOVASCULAR EVENTS



CARDIOVASCULAR DISEASE - PRIMARY PREVENTION

CONTROL OF CONVENTIONAL RISK FACTORS: ▶▶| Smoking cessation; ▶▶| Dyslipidemia; ▶▶| HTN; ▶▶| DM; ▶▶| Weight & Diet; ▶▶| Physical exercise

ASA: **not recommended as part of routine primary prevention**

- ★ **Antithrombotic Trialists' Collaboration**: **marginal benefit of ASA for primary prevention (high NNT);** bleeding risk
- **Consider ASA for primary prevention**: in the presence of a low bleeding risk but high cardiovascular risk (subclinical atherosclerosis; multiple risk factors; family history of premature cardiovascular disease) (Class IIb recommendation; C)

CARDIOVASCULAR DISEASE - SECONDARY PREVENTION

Smoking	Complete cessation
Dyslipidemia	High dose statin; Target → ≥ 50% ↘ LDL
HTN	Target BP < 140/90 (< 140/85 in the presence of DM)

Antiplatelet therapy	ASA: for life (★ Antithrombotic Trialists') • Clopidogrel as alternative (★ CAPRIE) • No benefit of ASA + Clopidogrel combination (★ CHARISMA)
ACE inhibitors	As secondary prevention for all patients (especially when LVEF ≤ 40% or HTN or DM or CRF)
BB	• LVEF ≤ 40%: Long term • Normal LVEF: can be stop 3 years after ACS • Antianginal: Long term
DM	HbA1c < 7%
Physical exercise	> 30 min moderate exercise 5 x per week
Obesity	• BMI: 18.5 - 24.9 kg/m² • Waist: M < 102 cm and F < 88 cm
Healthy diet	Healthy and balanced diet
Influenza vaccine	Annually
Hormonal therapy; NSAID	Avoid

9.3/ SMOKING CESSATION

30% of deaths related to CAD can be attributed to smoking

BENEFITS: reduction of cardiovascular risk to achieve a similar level to that of nonsmokers after 5 years of smoking cessation

INTERVENTION

1) Confirm that the patient is a smoker; **2)** Strongly recommend smoking cessation; **3)** Ask the patient whether he/she wants to stop smoking (if the patient refuses, suggest reducing consumption ± nicotine replacement therapy); **4)** Establish a plan and a date for complete cessation; **5)** Inform the patient's friends and relatives; **6)** Remove all objects related to smoking; **7)** Cease all activities related to smoking; **8)** Have a plan in the case of temptation / relapse; **9)** Propose drug therapy; **10)** Propose support by a smoking cessation center; **11)** **www.smokefree.gov** ; **12)** Ensure regular follow-up

DRUG THERAPY

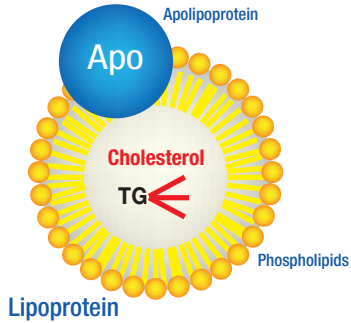
Nicotine gum	**Initially 1 gum every 1–2 h then decrease (maximum: 24 gums per day)** • ≤ 24 cigarettes / day: 2 mg gum • ≥ 25 cigarettes / day: 4 mg gum	• 6-month abstinence rate: 19% • **Adverse effects**: Nausea; Oropharyngeal irritation
Transdermal nicotine patch	• < 10 cigarettes / day: 14 mg patch for 6 weeks then 7 mg patch for 4 weeks then stop • > 10 cigarettes / day: 21 mg patch for 6 weeks then 14 mg patch for 2 weeks then 7 mg patch for 2 weeks	• 6-month abstinence rate: 23% • **Adverse effects**: Local skin reaction; Nausea; Insomnia
Bupropion SR	• Inhibits dopamine and norepinephrine reuptake • Bupropion SR 150 mg PO daily for 3 days then bid for 12 weeks then stop • Start 10 days before smoking cessation • Can be combined with nicotine replacement therapy	• 6-month abstinence rate: 24% • **Adverse effects**: Decreased seizure threshold; Insomnia; Xerostomia; Nightmares

Varenicline	• Partial agonist of acetylcholine nicotinic receptor • Varenicline 0.5 mg PO daily for 3 days then bid for 3 days then 1 mg bid for 11 weeks then stop • Start 1 to 2 weeks before smoking cessation • Can be combined with nicotine replacement therapy	Contraindicated in the case of pregnancy or breastfeeding or CRF or mental illness

9.4/ DYSLIPIDEMIA

DIET: source of triglycerides (glycerol bound to 3 fatty acid chains) and dietary Cholesterol

LIPOPROTEINS: transport TG and cholesterol in the blood



CHYLOMICRONS: large nonatherogenic lipoproteins transporting TG from the gastrointestinal tract; apoB48

VLDL: large nonatherogenic lipoproteins transporting TG from the liver; apoB100

LDL: **atherogenic lipoproteins responsible for atherosclerosis; mainly contain cholesterol; apoB100** +

- **Calculated LDL (mmol/L) = TC - HDL - (0.45 x TG) (valid if TG < 4.5 mmol/L)**
- **Calculated LDL (mg/dL) = TC - HDL - (TG / 5) (valid if TG < 400 mg/dL)**

NON-HDL CHOLESTEROL (= TC - HDL): cholesterol contained in LDL - VLDL - IDL - Lp(a); predictive of cardiovascular risk

- **ApoB**: comprises LDL - VLDL - IDL - Lp(a)

HDL: antiatherogenic properties; contains apolipoprotein **ApoA1**

HYPERTRIGLYCERIDEMIA: **TG-enriched LDL → formation of smaller and denser LDL (due to modification by hepatic lipase) → dense, atherogenic LDL** +

- **HyperTG**: TG-enriched HDL (CTEP) → ↗ recovery of HDL by the liver → **↘ HDL** +
- **HyperTG**: associated with metabolic syndrome **(↗ TG; ↘ HDL; dense, atherogenic LDL)** +
- **HyperTG: risk of pancreatitis** (especially if TG > 10 mmol/L or > 885 mg/dL)

LP(a): apolipoprotein(a) bound to a molecule of LDL; associated with an increased risk of cardiovascular events; plasma concentration is genetically determined

SCREENING FOR DYSLIPIDEMIA

- Male ≥ 40 years
- Female ≥ 50 years (or postmenopausal)
- DM
- HTN
- Smoking
- BMI > 27 kg/m²
- CRF - CrCl < 60 mL/min
- Atherosclerosis
- Family history of premature CAD (M < 55 years; F < 65 years)
- Family history of dyslipidemia
- SLE - RA - Psoriatic arthritis - Ankylosing spondylitis - Inflammatory bowel disease
- COPD
- Erectile dysfunction
- HIV (treated with antiretroviral agents)
- Clinical features of familial dyslipidemia (xanthomas; xanthelasmas; arcus senilis)

DYSLIPIDEMIA: UNDERLYING CAUSES

HYPERCHOLESTEROLEMIA: Hypothyroidism; Cholestasis; Nephrotic syndrome; CRF; Cushing; Corticosteroids; Anorexia; HIV protease inhibitors

HYPERTRIGLYCERIDEMIA: Obesity; DM; Alcohol; CRF; Hypothyroidism; Corticosteroids; Antipsychotics (Clozapine; Olanzapine); Nonselective BB; Thiazides; Cyclosporine; HIV protease inhibitors; Retinoic acid; Hormonal therapy; Sirolimus; Bile acid sequestrants

↘ **HDL**: Smoking; Obesity; Sedentary lifestyle; DM; CRF; HyperTG; Nonselective BB; Corticosteroids; Anabolic steroids; Cyclosporine

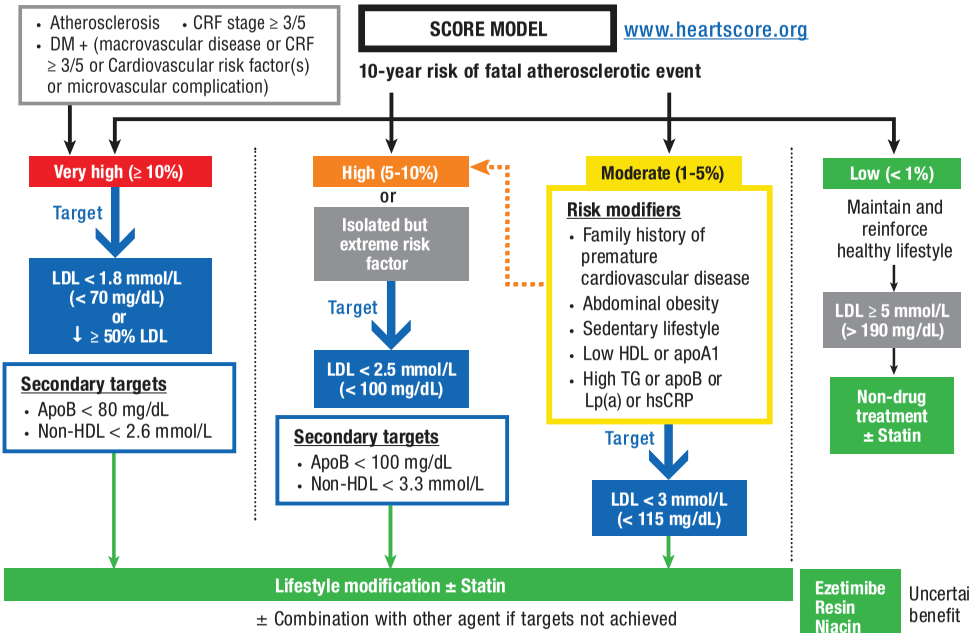
GENETIC DISORDERS OF LIPOPROTEINS

Familial hyper-cholesterolemia	↗ **LDL**	• **LDL–R receptor mutation** • 1,000 mutations identified • Autosomal dominant	• Arcus senilis • Xanthelasmas • **Pathognomonic tendinous xanthomas** (extensor tendons; MCP; Achilles tendon) • Premature CAD
Defective Apo B100	↗ **LDL**	• ↘ Affinity for LDL-R receptor • Autosomal dominant	• Similar presentation to familial hyper-cholesterolemia
Familial LPL deficiency	↗ **TG**	• **Abnormal catabolism of chylomicrons** and VLDL	• **Pancreatitis** • **Lipemia retinalis** • **Eruptive xanthomas** • **Lactescent serum**
Familial Apo-C-II deficiency	↗ **TG**	• **Apo–CII is the LPL activator**	• Similar presentation to familial LPL deficiency
Familial dysbeta-lipoproteinemia	↗ **TC** ↗ **TG**	• **Homozygote for ApoE2** (less effective binding to hepatic receptors) • Accumulation of **remnant lipoproteins** (IDL; remnant chylomicrons)	• Premature CAD • **Tuberous xanthomas** (elbows; knees) • **Palmar xanthomas** • **Consider diagnosis:** ApoB (g/L) / TC (mmol/L) ratio < 0.15

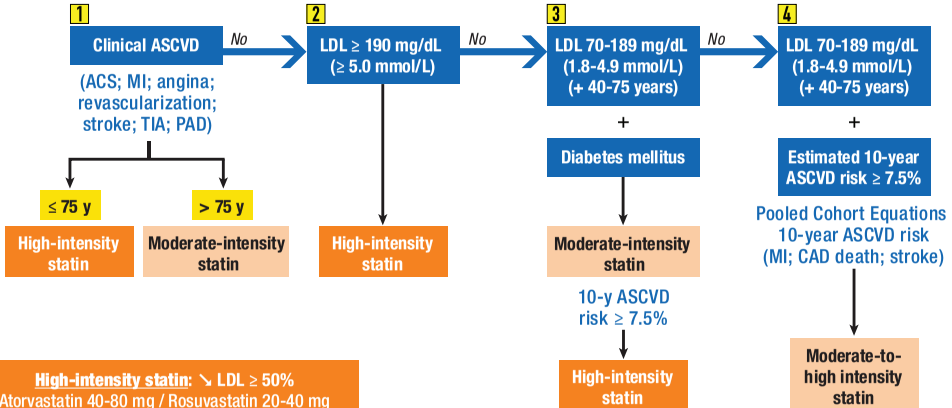
Familial combined hyperlipidemia	A) ↗ **VLDL** (↗ **TG**) or B) ↗ **LDL** (↗ **TC**) or C) ↗ **VLDL** and ↗ **LDL** (↗ **TG** and ↗ **CT**)	• 1-2% of the population • Extremely heterogeneous • Interactions between multiple genes and environment • Hepatic overproduction of lipoproteins apo-B100 (associated with VLDL) • Defective LPL in 1/3 of patients (↗ TG)	• Xanthelasmas • Arcus senilis • Premature CAD • Dense, atherogenic LDL • **Consider diagnosis**: Apo B > 120 mg/dL + TG > 1.5 mmol/L + family history of premature CAD
Familial ↘ HDL	↘ **HDL**	a) Apo A-I deficiency b) Tangier (CERP protein dysfunction) c) Familial LCAT deficiency	

MANAGEMENT - CANADIAN TARGETS

* **Intermediate risk with no indication for treatment**: consider statin if Lp(a) > 300 mg/L or hsCRP > 2.0 mg/L (with ★ JUPITER inclusion criteria) or albumin/creatinine ratio > 3 mg/mmol or positive stress test or carotid IMT > 1.0 mm (or plaque) or ABI < 0.9 or coronary calcium score > 100



• Atherosclerosis • CRF stage ≥ 3/5
• DM + (macrovascular disease or CRF ≥ 3/5 or Cardiovascular risk factor(s) or microvascular complication)
SCORE MODEL
www.heartscore.org
10-year risk of fatal atherosclerotic event
Very high (≥ 10%)
Target
LDL < 1.8 mmol/L (< 70 mg/dL) or ↓ ≥ 50% LDL
Secondary targets
• ApoB < 80 mg/dL
• Non-HDL < 2.6 mmol/L
High (5-10%)
or
Isolated but extreme risk factor
Target
LDL < 2.5 mmol/L (< 100 mg/dL)
Secondary targets
• ApoB < 100 mg/dL
• Non-HDL < 3.3 mmol/L
Moderate (1-5%)
Risk modifiers
• Family history of premature cardiovascular disease
• Abdominal obesity
• Sedentary lifestyle
• Low HDL or apoA1
• High TG or apoB or Lp(a) or hsCRP
Target
LDL < 3 mmol/L (< 115 mg/dL)
Low (< 1%)
Maintain and reinforce healthy lifestyle
LDL ≥ 5 mmol/L (> 190 mg/dL)
Non-drug treatment ± Statin
Lifestyle modification ± Statin
± Combination with other agent if targets not achieved
Ezetimibe
Resin
Niacin
Uncertain benefit



High-intensity statin: ↘ LDL ≥ 50%
Atorvastatin 40-80 mg / Rosuvastatin 20-40 mg

Moderate-intensity statin: ↘ LDL 30-50%
Atorvastatin 10-20 mg / Rosuvastatin 5-10 mg / Simvastatin 20-40 mg / Pravastatin 40-80 mg

Less evidence for statin therapy in NYHA II-IV HF or Hemodialysis

ASCVD: Atherosclerotic cardiovascular disease

Consider statin therapy

- LDL ≥ 160 mg/dL (≥ 4.1 mmol/L)
- Evidence of genetic hyperlipidemia
- Family history of premature ASCVD (< 55 y M - < 65 y F)
- Hs-CRP ≥ 2 mg/L
- CAC ≥ 300 Agatston units
- ABI < 0.9

NONDRUG TREATMENT: healthy diet; diet rich in omega-3 fatty acids; target healthy weight (BMI 18.5 to 24.9 kg/m²); regular physical exercise; smoking cessation; moderate alcohol consumption (maximum: 2 glasses per day for M and 1 glass per day for F)

DRUG TREATMENT: **First-line Statin**

HYPERTRIGLYCERIDEMIA: avoid alcohol and secondary causes; ↘ carbohydrates; increase omega-3 consumption; exercise and weight loss; control of DM

- **› TG > 10 mmol/L (> 885 mg/dL) → Fibrate for prevention of pancreatitis**
- **› TG 5-10 mmol/L (440-885 mg/dL) → Consider Fibrate (undemonstrated benefit)**

↘ **HDL**: smoking cessation; weight loss; exercise; moderate alcohol consumption

- **› Niacin**: no benefit in ★ AIM-HIGH and ★ HPS2-THRIVE studies

STATINS (HMG–COA REDUCTASE INHIBITORS)		
Atorvastatin	10-80 mg	• **↘ LDL (30-50%)** • ↘TG (10-30 %); ↗ HDL (5-10 %) • ↘ intracellular cholesterol synthesis → ↗ expression of LDL-R receptor • **Pleiotropic effects**: stabilization of atherosclerotic plaque; antiinflammatory effect; antithrombotic effect; improves endothelial function • **Adverse effects**: ↗ Transaminases; Myalgia / Myositis / Rhabdomyolysis; Drug interactions; ↗ risk of DM
Fluvastatin	20-80 mg	
Lovastatin	20-80 mg	
Pravastatin	10-40 mg	
Rosuvastatin	5-40 mg	
Simvastatin	10-40 mg	
BILE ACID SEQUESTRANTS (RESINS)		
Colesevelam	4 to 6 tablets (in 1 or 2 daily doses)	• **↘ LDL (15-30 %)** • **Adverse effects:** GI symptoms (constipation; discomfort); ↘ absorption of medications; ↗ TG
Colestipol	1 or 5 g / unit; 2-6 units / days (with meals)	
CHOLESTEROL ABSORPTION INHIBITOR		
Ezetimibe	10 mg	• **↘ LDL (20 %)** • Interferes with NPC1-L1 protein of intestinal epithelial cells • ★ **IMPROVE-IT:** Ezetimibe + Simvastatin vs. Simvastatin post ACS; ↘ MI and Stroke
FIBRATES		
Fenofibrate	200 mg	• **↘ TG (35-50 %)** • ↗ HDL (5-10 %); ↘ LDL (10-20 %) • ↗ LPL activity; ↘ Hepatic secretion of VLDL • **No benefit in ★ ACCORD study** • **Adverse effects**: ↗ Creatinine (adjust according to CrCl); Myotoxicity (avoid Gemfibrozil with statin); Rash; Drug interactions; ↗ Transaminases
Bezafibrate	400 mg	
Gemfibrozil	600 mg bid	

NICOTINIC ACID		
Niacin	1 g tid	• ↗ **HDL (25 %); ↘ TG (30 %); ↘ LDL (20 %)** • ↗ Hepatic production of apo A1 • ↘ HDL catabolism • ↘ Hepatic production of VLDL • **No benefit in ★ AIM-HIGH and ★ HPS2-THRIVE studies** • **Adverse effects**: Flushing (↘ with ASA); Hyperuricemia; Hyperglycemia; Hepatotoxicity; Gastritis
Slow-release niacin (Niaspan)	1-2 g daily	
CETP INHIBITORS		
↗ HDL; Anacetrapib; Dalcetrapib (no benefit in ★ dal–OUTCOMES); Evacetrapib		
PCSK9 INHIBITORS		
↘ LDL ★ **ODYSSEY long term**: ↘ LDL (62 %); ↘ MACE with Alirocumab vs. Placebo ★ **OSLER**: ↘ LDL (61 %); ↘ cardiovascular events and MACE with Evolocumab vs. Placebo		

STATINS

★ **CHOLESTEROL TREATMENT TRIALISTS': each 1 mmol/L (40 mg/dL) ↘ of LDL → 20-25% ↘ RR of cardiovascular mortality or myocardial infarction** +

PRIMARY PREVENTION: ★ WOSCOPS (Pravastatin); ★ AFCAPS/TexCAPS (Lovastatin); ★ HPS (Simvastatin); ★ ASCOT (Atorvastatin); ★ JUPITER (Rosuvastatin)

SECONDARY PREVENTION: ★ 4S (Simvastatin); ★ CARE (Pravastatin); ★ LIPID (Pravastatin); ★ HPS (Simvastatin)

› **Intensive treatment:** ★ A-to-Z and ★ SEARCH (Simvastatin); ★ PROVE-IT, ★ TNT, ★ ALLIANCE, ★ IDEAL and ★ SPARCL (Atorvastatin)

ADVANCED HEART FAILURE (LVEF < 30 %): no benefit (★ CORONA; ★ GISSI-HF)

RENAL FAILURE ON DIALYSIS: no benefit (★4D; ★AURORA)

MONITORING OF STATIN THERAPY

LIPID PROFILE: **At 4 to 12 weeks; then annually when dose adjusted and targets achieved**

DECREASING DOSE: may be considered when LDL < 1.0 mmol/L (< 40 mg/dL) +

MYALGIA: Discontinue Statin then resume several weeks later to **prove toxicity** (+ monitoring of CK)

› **Proven toxicity**: **A)** Reintroduce the same statin at a lower dose; **B)** Fluvastatin; **C)** Rosuvastatin 5-10 mg daily (or every 2 days or once a week); **D)** Ezetimibe - Niacin - Fibrate

› **Consider other conditions**: Hypothyroidism; CRF; liver disease; PMR; steroid myopathy; vitamin D deficiency; primary muscle diseases

MYOSITIS: myalgia + ↗ CK > ULN

RHABDOMYOLYSIS: severe myalgia; CK > 10,000 IU/L; Myoglobinuria; ± ARF

RISK FACTORS FOR MYOPATHY: statin dose; drug interactions; > 75 years; CRF (prefer Atorvastatin); liver disease; alcohol; pre-existing myopathy

AST – ALT		CK	
Baseline measurement and as necessary		Assay as necessary in the presence of myalgia	
↗ < 3 x ULN	↗ ≥ 3 x ULN	↗ ≤ 5 x ULN	↗ > 5 x ULN
• Continue treatment • AST - ALT in 6 weeks • If stable → stop monitoring AST - ALT	• Discontinue Statin • Consider DDx (alcohol; drugs; NASH) • Monitor AST - ALT until normalization **Normalization** a) Reintroduce at a lower dose b) Different statin c) Ezetimibe - Niacin - Fibrate	• Continue statin in the absence of symptoms • Repeat CK in 6 weeks • Discontinue Statin in the presence of symptoms or ↗ CK • If stable and asymptomatic → stop monitoring CK	• Discontinue Statin • Consider rhabdomyolysis (± hydration) • Monitor CK until normalization • Consider DDx **Normalization** a) Reintroduce at a lower dose b) Different statin c) Ezetimibe - Niacin - Fibrate

9.5/ HYPERTENSION

ASSESSMENT

DIAGNOSIS OF HYPERTENSION		
Office	**1st VISIT:** SBP ≥ 140 and/or DBP ≥ 90	
	SUBSEQUENT VISIT: • Diagnosis of HTN if **target organ damage or DM or GFR < 60 mL/min** • Diagnosis of HTN if **SBP ≥ 180 and/or DBP ≥ 110** • Otherwise › **Office**: diagnosis of HTN if **SBP ≥ 160 and/or DBP ≥100** x first 3 visits (mean) › **Office**: diagnosis of HTN if **SBP ≥ 140 and/or DBP ≥ 90** x first 5 visits (mean) › **ABPM or BP measured at home**	
ABPM (24 h)	• Daytime SBP: ≥ 135 or • 24-hour SBP: ≥ 130 or • Night: SBP ≥ 120; ↘ < 10 %	• Daytime DBP: ≥ 85 or • 24-hour DBP: ≥ 80 or • Night: DBP ≥ 70; ↘ < 10 %
BP at home	Daytime SBP: ≥ 135 mmHg	Daytime DBP: ≥ 85 mmHg
	• ≥ 2 readings daily (on getting out of bed and at bedtime) for 7 days (mean of days 2 to 7) • Recommended apparatus: www.hypertension.ca	
Hypertensive emergency	HTN diagnosed immediately	

STAGE OF HTN		
Grade 1 140-159 and/or 90-99	**Grade 2** 160-179 and/or 100-109	**Grade 3** ≥ 180 and/or ≥ 110

BLOOD PRESSURE MEASUREMENT TECHNIQUE

a) After resting for 5 min; no coffee or cigarettes for > 30 min; legs uncrossed; **b)** Patient seated in a chair with a back with the arms level with the heart; **c)** Inflatable cuff covers **> 80% of the arm circumference**; Cuff > 3 cm above the cubital fossa; **d)** Inflate to 30 mmHg above the level at which the radial pulse is lost; **e)** Deflate by 2 mmHg per beat; **f)** ≥ 3 measurements on the same arm (determine the mean of the last 2 measurements); **g)** Measure BP in both arms; **h)** Measure BP 1 min and 3 min after standing (rule out OH)

- **First audible sound = SBP (Korotkoff phase I)**
- **Last audible sound = DBP (Korotkoff phase V)**
  - If sounds persist until 0 mmHg, use the point at which the sounds become softer to define DBP (phase IV)

WORK-UP: Electrolytes; Creat; Urinalysis; Albumin/creat ratio; Fasting glucose; Lipids; CBC; ECG

ABPM (AMBULANT BLOOD PRESSURE MONITORING): verify response to treatment; nocturnal HTN (insomnia; OSAHS; obesity; CRF; OH; dysautonomia); evaluate fluctuating BP

- **White coat syndrome**: high BP in the doctor's office; home BP or daytime ABPM < 130-135/80-85 mmHg; no signs of target organ damage
- **Masked HTN:** normal BP in the doctor's office; ↗ daytime BP (stress; work...)

SEARCH FOR TARGET ORGAN DAMAGE

HEART DISEASE: CAD; Heart failure; LVH (ECG; TTE)

CEREBROVASCULAR DISEASE: stroke; TIA; Intracerebral hemorrhage; SAH; Vascular dementia; Carotid IMT ≥ 1 mm or plaques

PERIPHERAL ARTERY DISEASE (PAD): Aortic dissection; AAA; Claudication - Leg ischemia; ABI < 0.9

RENAL DISEASE: Hypertensive nephroangiosclerosis; CrCl < 60 mL/min; Microalbuminuria (30-300 mg/24 h or albumin/creatinine ratio 3.4-34 mg/mmol or 30-300 mg/g) or Macroalbuminuria

HYPERTENSIVE RETINOPATHY: Hemorrhages; microaneurysms; cotton wool spots or hard exudates; papilledema

UNDERLYING CAUSES OF HYPERTENSION

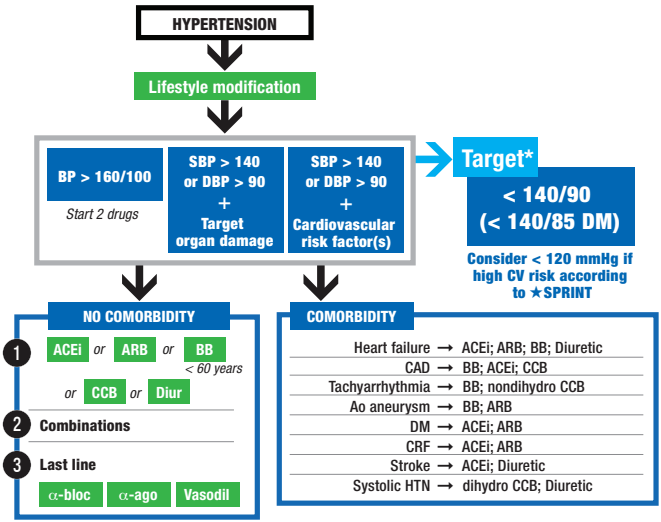
LOOK FOR AN UNDERLYING CAUSE IN THE PRESENCE OF: severe HTN; sudden onset or sudden deterioration of HTH; treatment failure; target organ damage disproportionate to the duration of HTN

Chronic renal disease	• Salt and water retention / Volume overload	• Urinalysis; Creatinine; Renal US; ± biopsy
Renovascular disease	• ▶▶| Chapter 8 (Peripheral vascular disease)	• Doppler renal arteries; MR angiography; CT angiography
CoA	• HTN in arms; ↘ Femoral pulses; Murmur between scapulae	• TTE; MR angiography; CT angiography; Cardiac cath
Primary hyper-aldosteronism	• Adenoma; Adrenal hyperplasia • Hypokalemia (spontaneous or severe diuretic-induced); Refractory HTN; ± Hypernatremia; Muscle weakness	• ↗ Plasma Aldosterone / Renin ratio (high sensitivity) • Suppression test with salt load (absence of ↘ of Aldosterone) • Adrenal CT scan or MRI • Adrenal vein catheterization

Cushing syndrome	• Truncal obesity; Violaceous striae; Thin skin; Muscle wasting; Osteoporosis; Buffalo hump	• Urinary cortisol • Suppression test (1 mg dexamethasone) • CT scan of adrenal glands
Pheochromo-cytoma	• Labile HTN; Headache; Profuse sweating; Palpitations • Exacerbated by stress / anesthesia / BB / caffeine / manipulation of the tumor • ± Dilated CM with HTN • Associated with Von Hippel-Lindau syndrome; MEN; Neurofibromatosis	• Plasma metanephrines (sensitivity 99%) • Urine metanephrines • CT scan or MRI of adrenal glands
Medications – Drugs	NSAID; Corticosteroids; Cyclosporine; Tacrolimus; EPO; Ephedrine; Decongestants; Cocaine; Amphetamines; Oral contraceptive; MAO inhibitors - SSRI; Midodrine; Anabolic steroids	

Other: Acromegaly; Hypothyroidism; Hyperparathyroidism; Pregnancy; Acute glomerulonephritis; Renal crisis (scleroderma); Rebound HTN (nonadherence to treatment); Smoking; Alcohol; Obesity; Sodium; OSAHS; Liquorice; Chronic pain; Intracranial neoplasm

MANAGEMENT



*** AMERICAN TARGETS (JNC 8)**

- < 60 years (or DM or CRF) → < 140/90 mmHg
- > 60 years → < 150/90 mmHg

★ **SPRINT**: sBP ≥ 130 mmHg + ≥ 50 years old + increased CV risk (CV disease; GFR 20-60 ml/min; Framingham > 15% /10-year; ≥ 75 years) + no diabetes / no prior stroke; target → **sBP < 120 mmHg vs. < 140 mmHg**; study terminated prematurely; ↘ **MACCE;** ↘ **Mortality**

NONDRUG TREATMENT: healthy weight (BMI 18.5 to 24.9 kg/m2); waist < 102 cm (M) and < 88 cm (F); regular physical exercise; moderate alcohol consumption; sodium < 2.4 g daily; healthy diet (rich in fruit and vegetables; low-fat; DASH diet); smoking cessation; relaxation techniques

DRUG TREATMENT

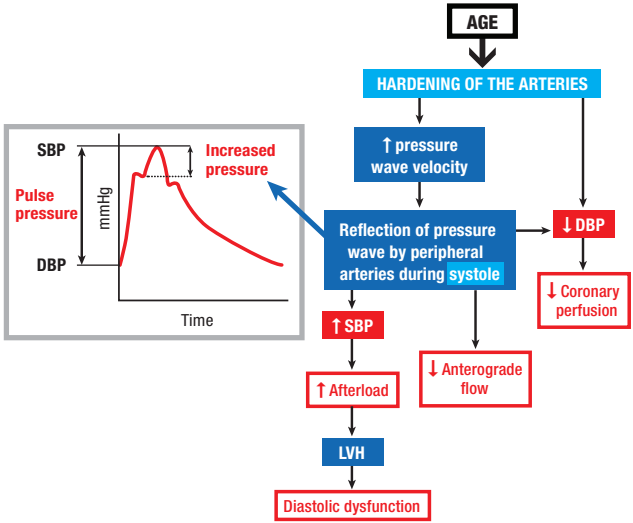
- ★ **ALLHAT**: Chlorthalidone and Lisinopril and Amlodipine are comparable
- ★ **ASCOT**: Hypertensive patients with ≥ 3 cardiovascular risk factors; Amlodipine + Perindopril superior to Atenolol + Thiazide (study terminated prematurely; ↘ stroke, ↘ mortality)
- ★ **ACCOMPLISH**: Hypertensive patients with CAD or high risk of CAD; **Benazepril + Amlodipine superior to Benazepril + HCTZ**

ANGIOTENSIN–CONVERTING ENZYME (ACE) INHIBITORS		
Benazepril	5 mg to 40 mg qd	• ↗ Bradykinin (cough; angioedema) • **Accept ↗ creatinine ≤ 30%** • Deterioration of renal function with bilateral renal artery stenosis • Hyperkalemia
Captopril	6.25 mg tid to 50 mg tid	
Cilazapril	1.25 mg to 10 mg qd	
Enalapril	2.5 mg to 40 mg qd	
Fosinopril	10 mg to 40 mg qd	
Lisinopril	5 mg to 40 mg qd	
Perindopril	2.5 to 10 mg qd (2 to 8 mg in Canada)	
Quinalapril	5 mg to 40 mg qd	
Ramipril	1.25 mg to 10 mg qd	
Trandolapril	0.5 mg to 4 mg qd	
ANGIOTENSIN II RECEPTOR BLOCKERS (ARB)		
Candesartan	8 mg to 32 mg qd	• ARF; Hyperkalemia; OH; Angioedema • Deterioration of renal function with bilateral renal artery stenosis • Do not add ARB to ACE inhibitors (harmful effect in ★ONTARGET)
Irbesartan	75 mg to 300 mg qd	
Losartan	25 to 100 mg qd	
Olmesartan	20 mg to 40 mg qd	
Telmisartan	20 mg to 80 mg qd	
Valsartan	40 mg to 320 mg qd	
DIRECT RENIN INHIBITORS		
Aliskiren	150 mg to 300 mg qd	Adverse effect of pro-renin?
CALCIUM CHANNEL BLOCKERS		
Amlodipine	5 mg to 10 mg qd	• Dihydropyridines (Amlodipine and Nifedipine): OH; leg edema; flushing; headache • Non-dihydropyridines (Diltiazem and Verapamil): negative inotropic agent; negative chronotropic agent
Nifedipine	XL: 30 mg to 120 mg qd	
Verapamil	SR: 120 mg qd to 240 mg bid	
Diltiazem	CD: 120 mg to 360 mg qd	

DIURETICS		
Indapamide	1.25-2.5 mg daily	• Avoid thiazides if CrCl < 30 mL/min • Adverse effects (thiazides): hyponatremia; hypomagnesemia; hypokalemia; OH; glucose intolerance; hypercalcemia; ARF; sulfonamide allergy; gout
Chlorthalidone	12.5-50 mg daily	
Hydrochlorothiazide	6.25-50 mg daily	
Metolazone	2.5-10 mg daily	
Bumetanide	0.5-5 mg daily	
Furosemide	20-600 mg daily	
Torsemide	2.5-10 mg daily	
Eplerenone	25-100 mg daily	
Spironolactone	25-100 mg daily	
Triamterene	50-300 mg daily	
Amiloride	5-10 mg daily	
BETA-BLOCKERS		
Acebutolol	100 mg bid to 400 mg bid	Bronchospasm; Bradycardia; Negative inotropic agent; Exacerbation of PAD; Fatigue; Erectile dysfunction; Rebound effect on withdrawal; Unopposed alpha stimulation (pheochromocytoma); ↗ TG and ↘ HDL (nonselective); Masks symptoms of hypoglycemia; glucose intolerance
Atenolol	25 mg to 100 mg qd	
Bisoprolol	2.5 mg to 10 mg qd	
Carvedilol	3.125 mg bid to 50 mg bid	
Labetalol	100 mg bid to 400 mg bid	
Metoprolol	25 mg bid to 100 mg bid	
Nadolol	40 mg to 240 mg qd	
Nebivolol	2.5 mg to 20 mg qd	
Pindolol	2.5 mg bid to 40 mg bid	
Propranolol	LA: 80 mg to 320 mg qd	
Timolol	2.5 mg bid to 20 mg bid	
ALPHA-BLOCKERS		
Doxazosin	1 mg to 16 mg qd	• Not recommended as first-line • OH; Fluid retention (risk of heart failure) • Doxazosin used as third line in ★ ASCOT
Prazosin	0.5 mg tid to 5 mg tid	
Terazosin	1 mg to 20 mg qd	
CENTRAL ALPHA-ADRENERGIC AGONISTS (VASOMOTOR ACTIVITY CENTER)		
Methyldopa	250-3000 mg daily	Sedation; Dry mouth; Impotence; Galactorrhea; ANA+; Autoimmune anemia
Clonidine	0.1 mg to 0.8 mg bid	Sedation; Dry mouth; Rebound effect on withdrawal

DIRECT VASODILATORS		
Hydralazine	10 mg to 50 mg qid	• Relaxation of precapillary arterioles • Reflex sympathetic activation; Lupus
Nitroglycerin	Imdur: 60-240 mg / 24h Nitrodur: 0.2 to 0.8 mg/h	Nausea; Headache; Hypotension; Tolerance

HYPERTENSION IN THE ELDERLY



★ **HYVET**: > 80 years; SBP > 160 mmHg; Indapamide / Perindopril vs Placebo; Benefit of treatment (↘ all-cause mortality; ↘ adverse events)

INITIATE TREATMENT IF SBP > 160 mmHg (no RCT with SBP < 160 mmHg)

› **Target → SBP ≤ 150 mmHg**
- Caution when DBP < 60 mmHg
- Monitoring of adverse effects: BP supine-standing

PSEUDOHYPERTENSION: HTN on sphygmomanometer, but normal BP on intraarterial measurement; secondary to rigid arteries that are not compressible by the cuff

› **Osler's maneuver**: radial pulse palpable when cuff inflated

TREATMENT-RESISTANT HYPERTENSION

BP > 140/90 mmHg despite ≥ 3 medications at adequate doses (including a diuretic)

ETIOLOGIES: nonadherence; failure to comply with salt restriction; dehydration (↗ stimulation of renin and aldosterone); **insufficient dose of diuretic; HTN secondary to an underlying cause**; hyperaldosteronism; OSAHS

› **Pseudo-resistance**: **A)** White coat syndrome; **B)** Pseudohypertension in the elderly

MANAGEMENT: Combination of ≥ 3 medications; look for underlying cause; use a sufficient dose of diuretic; mineralocorticoid receptor antagonist; alpha-blocking agent (Doxazosin); percutaneous radiofrequency renal denervation (no benefit in ★ Symplicity HTN-3)

HYPERTENSIVE CRISIS

SBP ≥ 180 MMHG OR DBP ≥ 110 MMHG

HYPERTENSIVE URGENCY: absence of target organ damage

› Often associated with discontinuation of treatment, nonadherence to treatment and/or anxiety
› **Management:** gradual treatment (over 24-48 h); consider oral treatment (Captopril; Furosemide; Propranolol; Nifedipine); avoid target organ hypoperfusion

HYPERTENSIVE EMERGENCY: **target organ damage; immediate treatment required; invasive hemodynamic monitoring; target ↘ DBP by 10-15% x 30-60 min**

› **Retinal damage:** hemorrhages; exudates; papilledema
› **CNS damage:** Hypertensive encephalopathy (headache; irritability; altered state of consciousness); thrombotic stroke; hemorrhagic stroke; SAH
  • **Cerebral autoregulation:** ↗ intracerebral blood pressure when DBP > 110-130 mmHg (autoregulatory mechanisms no longer effective); risk of cerebral edema
› **Cardiac damage:** Aortic dissection; acute heart failure; acute coronary syndrome
› **Renal damage:** ARF
› **Other:** Eclampsia / HELLP syndrome; Microangiopathic hemolytic anemia

Nitroprusside	IV infusion: 0.25-10 µg/kg/min (short duration) Standard dilution: 50 mg/250 mL D5 %	Nausea; Vomiting; Cyanide toxicity; Avoid in the presence of CNS damage or ARF or liver failure
IV Nitroglycerin	Perfusion: 5-60 µg/min Standard dilution: 50 mg/250 mL D5 %	Headache; Vomiting; Methemoglobinemia; Tolerance
Labetalol	• IV bolus: 20-80 mg every 10 min • IV infusion: 2 mg/min (max 300 mg / 24 h) Standard dilution: 200 mg/160 mL NS (= 1 mg/mL)	Vomiting; Faintness; Nausea; Block; OH
Esmolol	• Bolus: 0.25-0.5 mg/kg/min x 4 min • IV infusion: 0.05-0.3 mg/kg/min Standard dilution: 2500 mg/250 mL	Hypotension; Nausea; Block
IV Nicardipine	IV infusion: 5-15 mg/h	Headache; Nausea; Flushing; Tachycardia

9.6/ DIABETES

TYPE 1 DM: autoimmune (or idiopathic) destruction of pancreatic beta cells

TYPE 2 DM: insulin resistance and/or abnormal insulin secretion

DIAGNOSIS

DIAGNOSIS OF DIABETES	PREDIABETES		
	Abnormal fasting blood glucose	**Glucose intolerance**	**Prediabetes**
• **Fasting blood glucose:** ≥ 7.0 mmol/L (≥ 126 mg/dL) or • **Random blood glucose**: ≥ 11.1 mmol/L (≥ 200 mg/dL) or • **Blood glucose 2 h after 75 g glucose load**: ≥ 11.1 mmol/L or • **HbA1c**: ≥ 6.5 %	**Fasting blood glucose:** 6.1 - 6.9 mmol/L (110 - 124 mg/dL) Rule out Glucose intolerance	**Blood glucose 2 h after 75 g glucose load:** 7.8 - 11.0 mmol/L (140 - 200 mg/dL)	**HbA1c:** 6.0 - 6.4% Rule out Glucose intolerance
	More intensive management of cardiovascular risk factors; consider Metformin or Acarbose		

GLYCEMIC CONTROL - TYPE II DIABETES

BENEFITS OF GLYCEMIC CONTROL

- **Reduction of microvascular complications**: retinopathy; nephropathy; neuropathy (★ DCCT - ★ UKPDS - ★ ADVANCE)
- **Little evidence concerning the benefit on macrovascular complications**: ★ ADVANCE and ★ VADT; ★ ACCORD demonstrated excess mortality for target HbA1c < 6%

GLYCEMIC CONTROL TARGETS		
HbA1c	**Fasting blood glucose & Preprandial blood glucose**	**2 h postprandial blood glucose**
≤ 7 % every 3 months (every 6 months when target achieved)	**4.0 - 7.0 mmol/L (72 - 126 mg/dL)**	**5.0 - 10.0 mmol/L** (5.0 - 8.0 when target HbA1c not achieved)

1) **NONDRUG TREATMENT**: weight loss (< 5%); balanced diet / follow-up by a nutritionist; regular moderate aerobic physical exercise (30 min; 5 times a week)
   - **Stress test prior to training program:** consider in patients at high-risk of cardiovascular disease (or with microvascular complication) in the case of training with an intensity greater than rapid walking
2) **FIRST-LINE DRUG TREATMENT:** Metformin
3) **SECOND-LINE DRUG TREATMENT:** in combination with Metformin
   - Sulfonylurea (or Meglitinide) and/or Incretins
   - Bedtime basal insulin therapy
4) **INSULIN THERAPY**: 3 approaches
   a) **Bedtime basal insulin therapy**: combined with oral antidiabetic; **starting dose of 10 units at bedtime**; increase by 1 unit per day, targeting a fasting blood glucose of 4.0-7.0 mmol/L (72 - 126 mg/dL); avoid nocturnal hypoglycemia
   b) **Premixed insulin**: **starting dose of 5-10 units bid** (before breakfast and before dinner); increase the morning dose by 1 unit, targeting evening blood glucose before dinner of 4.0 - 7.0 mmol/L (idem for the evening dose, targeting morning fasting blood glucose of 4.0 - 7.0 mmol/L)
   c) **Intensive insulin therapy: total daily dose = 0.3 to 0.5 kg unit**; 40% of the total dose as bedtime basal insulin therapy; 20% of the total dose as bolus doses tid with each meal

Biguanide	Metformin: 250 mg bid to 850 mg tid	Decreases hepatic glucose synthesis	**↘ HbA1c by 0.8%** **Adverse effects:** Nausea; Diarrhea; Lactic acidosis (contraindicated if GFR < 30 mL/min) Weight loss Benefit on the risk of MI and mortality in obese patients in ★UKPDS
Sulfonylureas	• Gliclazide: 60 mg qd to 120 mg qd • Glimepiride: 1 to 8 mg qd • Glyburide: 2.5 mg qd to 10 mg bid	Stimulates insulin secretion by the pancreas	**↘ HbA1c by 0.7%** **Adverse effects:** Hypoglycemia (prefer Gliclazide which is associated with the lowest risk of hypoglycemia); weight gain Benefit on the risk of MI in ★UKPDS
Meglitinide	Repaglinide: 0.5 mg tid to 4 mg qid	Stimulates insulin secretion by the pancreas	**↘ HbA1c by 1-1.5 %** Short duration of action (to be taken < 30 min before the meal) **Adverse effects:** Hypoglycemia; Weight gain
Incretin - GLP-1 analog ("glucagon-like peptide 1")	• Exenatide: 5 to 10 µg SC bid • Liraglutide: 0.6 to 1.8 mg SC daily	**GLP-1:** ↗ insulin secretion; ↘ glucagon secretion; delays gastric emptying	**↘ HbA1c by 1 %** **Weight loss** **Adverse effects:** Nausea; Vomiting
Incretin - DPP-4 inhibitors	• Sitagliptin: 100 mg qd • Linagliptin: 5 mg qd • Saxagliptin: 5 mg qd	Inhibits the breakdown of GLP-1	**↘ HbA1c by 0.7 %** Safe post-ACS (★EXAMINE; Alogliptin) **Adverse effects:** ↗ hospitalization for heart failure with Saxagliptin in ★SAVOR but not with Sitagliptin in ★TECOS
Alpha-glucosidase inhibitor	Acarbose: 25 mg tid to 100 mg tid	Decreases intestinal absorption of carbohydrates	**↘ HbA1c by 0.6 %** **Adverse effects:** Bloating
Thiazolidine-dione (TZD)	Pioglitazone: 15 mg to 45 mg qd	Increases peripheral insulin sensitivity	**↘ HbA1c by 0.8 %** **Adverse effects:** Weight gain; Edema; contraindicated in heart failure (★DREAM); bladder tumor; fracture

SGLT2 inhibitors	Canagliflozin Dapagliflozin Empagliflozin	↘ glucose reabsorption by the renal proximal tubule	↘ **All-cause mortality** with Empagliflozin in ★ EMPA-REG ↘ BP; Weight loss **Adverse effects:** urinary tract infections; candidiasis; ↗ LDL
RAPID ACTING INSULIN • Aspart (NovoRapid) • Lispro (Humalog)		• Onset of action: 10-15 min • Peak action: 1-2 h • Duration of action: 3-5 h	
REGULAR INSULIN • Humulin-R • Novolin ge Toronto		• Onset of action: 30 min • Peak action: 2-3 h • Duration of action: 6.5 h	
INTERMEDIATE-ACTING INSULIN • Humulin-N • Novolin ge NPH		• Onset of action: 1-3 h • Peak of action: 5-8 h • Duration of action: up to 17 h	
LONG-ACTING INSULIN • Detemir (Levemir) • Glargine (Lantus)		• Onset of action: 90 min • Duration of action: up to 24 h	
PREMIXED INSULIN Humulin 30/70; Novolin ge 30/70; Biphasic insulin aspart (NovoMix 30); Insulin lispro / lispro protamine (Humalog Mix25)…			

MANAGEMENT - TYPE II DIABETES

CARDIOVASCULAR RISK: **2- to 3-fold higher prevalence of coronary artery disease than in nondiabetic subjects; coronary artery disease occurs 10 years earlier**

CONTROL OF CARDIOVASCULAR RISK FACTORS: healthy weight; waist < 102 cm (M) and < 88 cm (F); BMI 18.5 - 24.9 kg/m2; healthy diet; regular physical exercise; smoking cessation

CONTROL BP: target BP < 140/85 and prefer ACEi (or ARB) as first-line treatment

› ★ **ACCORD-BP**: no benefit of targeting SBP < 120 versus < 140 mmHg

ANTIPLATELET THERAPY (ASA):

› **Secondary prevention**: indicated for all patients
› **Primary prevention**: uncertain benefit (ongoing ★ ASCEND and ★ ACCEPT-D studies); not recommended routinely; consider if high 10-year risk of cardiovascular events in the absence of bleeding risk (class IIb recommendation); **decision based on clinical judgment**

STATIN: ★ CARDS and ★ HPS studies of primary prevention demonstrated a benefit

› **European guidelines - Indications: A)** Very high risk ⟶ DMI or DMII + (macrovascular disease or CRF ≥ 3/5 or cardiovascular risk factors or microvascular complication); **B)** High risk ⟶ DMII + (absence of cardiovascular risk factors and absence of target organ damage)
› **Canadian guidelines - Indications**: Diabetes + (≥ 40 years or present for > 15 years in a patient ≥ 30 years or macrovascular disease or microvascular complication)
› **American guidelines - Indications**: Diabetes + 40-75 years + LDL ≥ 70 mg/dL (≥ 1.8 mmol/L)

ACEI: cardioprotective effect: (★ HOPE, ★ EUROPA and ★ ADVANCE); indicated in the presence of HTN or clinical macrovascular disease or ≥ 55 years or in the presence of a microvascular complication

› **ARB: when ACEi are not tolerated;** ★ ONTARGET ⟶ Telmisartan non-inferior to Ramipril; ★ TRANSCEND ⟶ no benefit of Telmisartan versus placebo (patients intolerant to ACEi)

NONINVASIVE ASSESSMENT OF CAD (PROGNOSTIC PURPOSES): Indications → **A)** Symptoms (retrosternal chest pain; dyspnea); **B)** Baseline ECG abnormalities; **C)** Atherosclerosis (PAD - TIA - stroke - murmur)

› **Revascularization**: **benefit of revascularization by bypass graft (versus PCI) on mortality and risk of MI (★ FREEDOM)** +

VACCINATION: Influenza (annually); Pneumococcus

OTHER: self-monitoring of blood glucose; screening for retinopathy (every 1-2 years); screening for neuropathy (big toe; Semmes-Weinstein 10 g monofilament test or 128 Hz tuning fork); examination of feet; prevention of diabetic ulcer; PDE-5 inhibitor for erectile dysfunction

HYPOGLYCEMIA: Blood glucose < 4 mmol/L (72 mg/dL) + symptoms (tremor; palpitations; anxiety; profuse sweating; nausea; confusion; weakness); **treatment with 15 g of oral carbohydrate or 1 mg of Glucagon SC (or IM) or 1 ampoule of 50% dextrose IV**

DIABETIC NEPHROPATHY

CHRONIC NEPHROPATHY: GFR < 60 mL/min and/or microalbuminuria or macroalbuminuria

SCREENING: albumin / creatinine ratio and serum creatinine (and GFR) every year

MANAGEMENT: optimal control of blood glucose and BP; ACEi or ARB; Nephrological follow-up if sustained deterioration or GFR < 30 mL/min or significant macroalbuminuria; aggressive treatment of cardiovascular risk factors (high risk of adverse events)

ALBUMINURIA			NEPHROPATHY		
	Albumin / creatinine ratio (mg/mmol)	**Albumin mg / 24h**	**Stage**	**Renal damage**	**GFR (mL/min)**
Normal	< 2.0	< 30	1	Minimal - Absent	≥ 90
Micro-albuminuria	2.0 - 20.0	30 - 300	2	Mild	60 - 89
Macro-albuminuria	> 20.0	> 300	3	Moderate	30 - 59
			4	Severe	15 - 29
			5	End-stage	< 15

9.7/ PHYSICAL ACTIVITY

PHYSIOLOGY OF EXERCISE

1) **↗ CARDIAC OUTPUT:** ↗ up to 4- to 6-fold
   a) ↗ **Stroke volume** (↗ venous return → Frank-Starling law; catecholamines → positive inotropes)
   b) ↗ **HR** (HRmax ≈ 220 - age)
2) **REDISTRIBUTION OF PERFUSION:** vasodilatation in muscles; vasoconstriction of other systems (except for CNS and heart)
3) **↗ O_2 EXTRACTION BY MUSCLES**
4) **↗ CORONARY PERFUSION:** ↗ up to fivefold; vasodilatation of coronary arterioles

› **MVO_2**: myocardial O_2 consumption; determined by **HR / SBP / LV end-diastolic volume / wall thickness / contractility** +

BENEFITS & RISKS

BENEFITS OF EXERCISE ON CONVENTIONAL CARDIOVASCULAR RISK FACTORS

- **HTN**: ↘ 3.4 / 2.4 mmHg
- **Dyslipidemia**: ↗ HDL 0.06 mmol/L (2.3 mg/dL); ↘ TG
- **Obesity**: ↘ 7 kg in 1 year (in combination with diet)
- **Diabetes:** ↘ HbA1c by 0.8%

IMPROVEMENT OF OTHER PARAMETERS: functional capacity; quality of life; mental health; endothelial function; inflammatory state; ischemic threshold

- **Physical activity**: **↘ mortality and ↘ cardiovascular events in patients with CAD** (meta-analyses); ↘ mortality and hospitalizations in patients with LVEF < 35% (★ HF-ACTION; after adjustments)

BENEFITS OF TRAINING: ↗ VO_2 max; ↗ stroke volume; lower HR for the same level of exercise (same HRmax); ↗ arteriovenous O_2 difference; delayed ventilatory threshold; ↘ MVO_2 for the same level of exercise

RISKS OF PHYSICAL EXERCISE

a) **< 35 years**: sudden death / arrhythmia / genetic condition (HCM; congenital coronary artery anomalies; myocarditis; ARVD; Channelopathy; CAD; Acute aortic syndrome; Aortic stenosis; DCM; WPW; *commotio cordis*)
b) **> 35 years:** CAD / MI (especially in sedentary subject performing unusually strenuous exercise)

INTENSITY OF PHYSICAL EXERCISE

1 MET: = O_2 consumption at rest while seated (3.5 mL O_2/kg/min)

< 3 METs	3 – 5 METs	5 – 7 METs	7 – 9 METs	> 9 METs
• Washing • Shaving • Dressing • Washing the dishes • Sewing • Playing a musical instrument • Golf (caddy) • Walking (3.2 kph) • Fishing • Pool	• Washing the windows • Electric lawnmower • Making a bed • Dancing • Golf • Sailing • Tennis (doubles) • Volleyball (6 players) • Ping-pong • Walking (6.4 kph)	• Manual lawnmower • Climbing stairs (slowly) • Badminton • Tennis (singles) • Basketball • Walking (8 kph) • Bike-riding (16 kph) • Swimming (breaststroke)	• Shoveling snow • Climbing stairs (moderate speed) • Canoe • Soccer • Jogging (8 kph) • Swimming (front crawl) • Bike-riding (19 kph) • Mountain-climbing	• Climbing stairs (rapidly) • Shoveling heavy snow • Handball • Squash • Running (> 10 kph) • Bike-riding (> 21 kph)

EVALUATION OF THE RISK OF PHYSICAL EXERCISE

PRE-TRAINING STRESS TEST: **A)** DM; **B)** Symptoms or multiple cardiovascular risk factors or known heart disease; **C)** Strenuous physical exercise by a sedentary subject (M > 45 years and F > 55 years)

CATEGORY	CHARACTERISTICS	MANAGEMENT
Class A: In good health	• M < 45 years or F < 55 years with no symptoms, no heart disease and no major cardiovascular risk factors • M > 45 years or F > 55 years with no symptoms, no heart disease and ≤ 1 major cardiovascular risk factor • M > 45 or F > 55 years with no symptoms, no heart disease with ≥ 2 major cardiovascular risk factors	• No restriction • No supervision required • Physical examination / Stress test as necessary (according to cardio-vascular risk factors / type of strenuous exercise)
Class B: Stable heart disease	• Stable CAD • Nonsevere valvular heart disease • Stable congenital heart disease (according to 36th Bethesda conference) • Stable cardiomyopathy (LVEF ≤ 30%) • Abnormal stress test (no class C abnormalities) **+** **CLINICAL CHARACTERISTICS** NYHA I or II; No decompensated heart failure; ≥ 6 METs; No ischemia < 6 METs; Normal BP response to exercise; No VT on effort - rest; Able to selfmonitor	• Individualized prescription **(50% of HR reserve then increase)** • Medical supervision with monitoring during the initial phase (6-12 sessions) • Nonmedical supervision thereafter until the patient is able to self-monitor
Class C: Moderate to high risk	• CAD • Nonsevere valvular heart disease • Moderate congenital heart disease (36th Bethesda conference) • Cardiomyopathy (LVEF ≤ 30%) • Partially controlled ventricular arrhythmia **+** **CLINICAL CHARACTERISTICS** NYHA III-IV; Stress test < 6 METs; Ischemia < 6 METs; Abnormal BP response to exercise; NSVT on exercise; History of cardiac arrest; Potentially dangerous medical condition	• Individualized prescription **(40% of HR reserve then increase)** • Medical supervision with monitoring until safety is confirmed (> 12 sessions) • Can be classified as class B when exercise is safe
Class D: Unstable condition	• Unstable ischemia • Severe valvular heart disease / symptoms • Severe congenital heart disease • Decompensated heart failure • Uncontrolled arrhythmia • Other condition worsened by exercise	• Exercise contraindicated • Target treatment of the disease

Fletcher GF, Balady GJ, Amsterdam EA. Exercise Standards for Testing and Training; A Statement for Healthcare Professionals From the American Heart Association. Circulation. 2001;104:1694-1740

COMPETITIVE SPORT: according to the 36th Bethesda conference

PRESCRIPTION OF AEROBIC (ISOTONIC) PHYSICAL EXERCISE

FREQUENCY: 5 times a week

DURATION: 30 min (in 10-min fractions if necessary)

INTENSITY: moderate

- **Target**: ideally 450 to 750 METs x min / week (1000 kcal / week)
- **Kcal/min**: = (METs x 3.5 x kg weight) / 200
- **Strenuous aerobic exercise**: 3 times a week; 20 min per session

MODERATE AEROBIC EXERCISE	VIGOROUS AEROBIC EXERCISE
• **% VO_2 max**: 45-59 % • **% HR reserve**: 45-59 % • **% HRmax**: 55-69 %	• **% VO_2 max**: 60-85 % • **% HR reserve**: 60-85 % • **% HRmax**: 70-90 %
• **Borg scale**: 12-13 / 20 Comfortable while talking (≈ ventilatory threshold ≈ 50 % VO_2Max)	• **Borg scale**: 14-16 / 20 Conversation is difficult during exercise
• **METs**: 4 - 6 METs (middle-aged) 5 - 7 METs (young) 3 - 5 METs (elderly) 2 - 3 METs (very elderly)	• **METs**: 6 - 8.5 METs (middle-aged) 7 - 10 METs (young) 5 - 7 METs (elderly) 3 - 4 METs (very elderly)
• **Type of exercise**: rapid walking; bike-riding; swimming; dancing; pool aerobics; elliptic exercise machine	• **Type of exercise**: rapid walking uphill; jogging; rapid swimming; hockey; singles tennis; shoveling snow

- **Target HR according to HR reserve**: = (prescribed % x HR reserve) + resting HR
- **HR reserve**: = HRmax on stress test - resting HR
- **HRmax**: = 220 - age
- **HRmax**: = HRmax on stress test limited by symptoms

- **Ischemia on stress test**: Target HR on exercise must be at least 10 bpm lower than ischemic threshold (or target HR = 70% of HR at the ischemic threshold)

PRESCRIPTION OF RESISTANCE TRAINING (STATIC; ISOMETRIC)

FREQUENCY: twice a week

CONTENT: 1-3 series of 8 to 12 repetitions of the prescribed load (counterweight machine or dumbbells)

8-10 MUSCLE GROUPS: Biceps; Triceps; Shoulders; Pectorals; Back; Abdominal muscles; Leg muscles

PRESCRIBED LOAD: maximum load that can be lifted once → 35% of this maximum load for arms and 45% for legs

9.8/ WEIGHT & DIET

WEIGHT CONTROL

BMI: = Mass (kg) / Height ² (m^2)

Underweight	BMI < 18.5 kg/m²
Healthy weight	BMI 18.5 - 24.9 kg/m²
Overweight	BMI 25.0 - 29.9 kg/m²
Obesity - Class I	BMI 30.0 - 34.9 kg/m²
Obesity - Class II	BMI 35.0 - 39.9 kg/m²
Obesity - Class III (morbid)	BMI ≥ 40 kg/m²

BENEFIT OF WEIGHT CONTROL ON CARDIOVASCULAR RISK FACTORS: ↘ BP; improves lipid profile (↘ TG; ↘ atherogenic lipoproteins; ↗ HDL); ↘ DM; ↘ OSAHS; ↘ inflammatory state; improves endothelial function

WEIGHT LOSS

BMI	**Target 18.5 - 24.9 kg/m²**
WAIST (midpoint between superior iliac crest and costal margin)	**Target < 102 cm M and < 88 cm F** (ideally < 94 cm M and < 80 cm F)

1) LIFESTYLE MODIFICATION: healthy diet; regular physical exercise; behavioral therapy (selfmonitoring; eat more slowly; eat smaller servings; nutritional education...)

- **Targets**: **weight loss of 5% in 3-6 months** (realistic target)
- **Measurements**: **energy deficit of 500 kcal per day** (loss of 1-2 pounds per week); Regular exercise program (30 min; 5 times a week)

2) DRUG TREATMENT: indicated after failure of nondrug treatment for 6 months with BMI > 30 kg/m² (or > 27 kg/m² with comorbidities)

Pancreatic lipase inhibitor	Orlistat 120 mg tid + fat-soluble vitamin supplement	Inhibits digestion and absorption of dietary fat by 30%	Bloating; Steatorrhea; Abdominal cramps; Renal stones
Selective serotonin agonist	Lorcaserin	Early satiety	Faintness; Nausea; Headache; URTI; Uncertain long-term safety (valvular heart disease?)

3) BARIATRIC SURGERY: indicated in the presence of class III obesity (or class II obesity with secondary comorbidities) and failure of other treatment modalities with an acceptable operative risk

- **Options**: Vertical gastroplasty with laparoscopic banding or laparoscopic Roux-en-Y gastric bypass

HEALTHY DIET

DASH diet or Mediterranean diet or AHA diet; emphasize intake of vegetables, fruits, whole grains, nontropical vegetable oils, nuts, low-fat dairy products, fish, poultry; limit intake of sodium - sweets - sugar-sweetened beverages - red meats

BENEFIT ON CONVENTIONAL CARDIOVASCULAR RISK FACTORS: ↘ LDL; ↘ BP; ↘ Weight; ↘ DM

MEDITERRANEAN DIET: rich in olive oil / nuts / fruit and vegetables; ↘ cardiovascular mortality in secondary prevention (★ Lyon diet heart study) and ↘ cardiovascular events in primary prevention (★ PREDIMED)

Total calories - Energy balance	**Intake equal to energy expenditure** **Normal intake: 22 kcal/kg (± 20%)**
Fat	**< 35 % of total energy intake**
Mono- and polyunsaturated fatty acids (fish; vegetable oils; nuts)	• Increase intake • **Omega-3 fatty acids → ↘** cardiovascular mortality (★ GISSI-Prevention)
Saturated fatty acids	< 7% of total energy intake Avoid red meat - high-fat dairy products - tropical oils (palm; coconut)
Trans fatty acids / Hydrogenated oils	Limit to a minimum; < 1% of total energy intake; ↗ LDL and ↘ HDL
Dietary cholesterol	< 200-300 mg daily
Carbohydrates	**45 - 60% of total energy intake** Prefer whole grain products - low-fat dairy products - fruit and vegetables Avoid carbohydrates with a high glycemic index (potatoes; white bread; white rice; soft drinks)
Proteins	**15 -20% of total energy intake**
Fibers (whole grains; fruit; vegetables; nuts)	Increase intake; 25 - 50 g daily
Fruit and vegetables	≥ 8-10 servings per day
Fish	At least twice a week
Sodium	< 2.4 g per day
Alcohol	M: 20 g per day (2 glasses); F: 10 g per day (1 glass) (caution in the presence of DM - HTN - Liver disease - History of alcohol abuse)
Red meat; High-fat dairy products	Limit to a minimum

METABOLIC SYNDROME

CENTRAL OBESITY (WAIST) USA - Canada: M: ≥ 102 cm; F: ≥ 88 cm Europid: M: ≥ 94 cm; F: ≥ 80 cm	+	**≥ 2 OF THE FOLLOWING RISK FACTORS** • TG ≥ 1.7 mmol/L (150 mg/dL) • HDL: M < 1.03 and F < 1.3 mmol/L (40 - 50 mg/dL) • BP ≥ 130/85 (or treated HTN) • Fasting blood glucose ≥ 5.6 mmol/L (100 mg/dL)

↗ risk of cardiovascular disease and DMII

MANAGEMENT: control of cardiovascular risk factor; regular exercise; weight loss

9.9/ OBSTRUCTIVE SLEEP APNEA SYNDROME

OBSTRUCTIVE APNEA: **absence of airflow for ≥ 10 s despite active ventilatory efforts**

OBSTRUCTIVE HYPOPNEA: ↘ airflow < 50% for ≥ 10 s with ↘ SaO_2 ≥ 4 %

APNEA-HYPOPNEA INDEX (AHI): mean number of episodes of apnea and hypopnea per hour (mild if AHI ≥ 5; severe if AHI ≥ 30)

CLINICAL FEATURES: snoring; daytime sleepiness; witnessed apnea during the night; morning headache; disorders of concentration

HARMFUL EFFECTS: sympathetic stimulation; transient hypoxemia; marked fluctuations of intrathoracic pressure (↗ afterload); nocturnal HTN; treatment-resistant HTN; diastolic dysfunction; nocturnal angina

ASSOCIATIONS: obesity; DM; metabolic syndrome; AF; CAD; stroke; heart failure; nonischemic dilated cardiomyopathy; PHT

DIAGNOSIS: Polysomnography (screening by nocturnal saturometry)

TREATMENT: Weight loss; CPAP; Oral device; Surgery

9.10/ DRIVING & AIR TRAVEL

	PRIVATE VEHICLE	COMMERCIAL VEHICLE
STEMI	1 month	3 months
NSTEMI - Significant damage (RWMA)	1 month	3 months
Unstable angina or NSTEMI without RWMA	48 h post-PCI (7 days in the absence of PCI)	7 days post-PCI (30 days in the absence of PCI)
CAD - PCI	48 h post-PCI	7 days post-PCI
CABG	1 month	3 months
LMCA	Disqualified if > 70%	Disqualified if > 50%
VF - Absence of reversible cause	6 months	Disqualified
Unstable VT	6 months	Disqualified
VT or VF - Reversible cause (MI; Electrocution; Drugs)	Disqualified until correction of reversible cause	
Stable sustained VT - LVEF < 30%	3 months	Disqualified
Stable sustained VT - LVEF ≥ 30%; without ICD	4 weeks	3 months
Symptomatic SSS	Disqualified until treatment	
LBBB or Bifascicular block or Mobitz I or Bifascicular block + 1st degree AV block	No restriction in the absence of alteration of LOC	No restriction in the absence of alteration of LOC and in the absence of higher grade of AV block on annual Holter
Mobitz II (infranodal)	Disqualified	Disqualified
Alternating RBBB and LBBB	Disqualified	Disqualified
3rd degree AV block	Disqualified	Disqualified

Pacemaker	1 week post-implantation (no alteration of LOC postimplantation; functioning pacemaker)	1 month post-implantation (no alteration of LOC postimplantation; functioning pacemaker)
ICD - Primary prevention (NYHA I to III)	4 weeks	Disqualified
ICD - Secondary prevention (VF or VT with alteration of LOC)	6 months	
ICD - Secondary prevention (stable VT; NYHA I to III)	1 week + interval associated with VT	
Therapy (ATP or shock) with alteration of LOC	6 months	
Brugada / Long QT / ARVD	6 months after episode with alteration of LOC	Disqualified
EPS (without induced VT) or ablation procedure	48 h	1 week
SVT / AF / Flutter with alteration of LOC	• Ablation: 48 h • Medical treatment: 3 months	• Ablation: 1 week • Medical treatment: 3 months
Classical vasovagal syncope - 1st episode	No restriction	No restriction
Classical vasovagal syncope - Recurrence (< 12 months)	1 week	12 months
Syncope with treated cause (e.g.: pacemaker)	1 week	1 months
Situational syncope	1 week	1 week
Unexplained syncope - 1st episode	1 week	12 months
Unexplained syncope - Recurrence (< 12 months)	3 months	12 months
AS	NYHA I or II; No alteration of LOC	Asymptomatic - NYHA I - Area ≥ 1 cm² - LVEF ≥ 35%
AR - MS - MR	NYHA I or II; No alteration of LOC	No alteration of LOC - NYHA I - LVEF ≥ 35%
Mechanical valve or Bioprosthesis	6 weeks Anticoagulation (if indicated) No thromboembolic complication	3 months NYHA I and LVEF ≥ 35% Anticoagulation (if indicated) No thromboembolic complication
NYHA I or II	No restriction	LVEF ≥ 35%
NYHA III	No restriction	Disqualified
NYHA IV	Disqualified	Disqualified

Heart transplant	6 week NYHA I or II	6 months NYHA I; LVEF ≥ 35% No ischemia on annual noninvasive test
LVAD - continuous flow ventricular assist device	2 months NYHA I-III	Disqualified
HCM	No alteration of LOC	Wall thickness < 30 mm; No syncope; No NSVT (annual Holter); No family history of sudden death; No ↘ BP on exercise

AIR TRAVEL

INDICATION FOR O_2: A) PaO_2 < 70 mmHg; **B)** CCS III/IV angina; **C)** NYHA III/IV heart failure; **D)** Cyanotic congenital heart disease; **E)** PHT - Right heart failure

Stable angina / NYHA I – II – III	O_2 if NYHA III
Post-myocardial infarction / NYHA I	6-8 weeks
Heart failure / NYHA I - II - III	O_2 if NYHA III
Valvular heart disease / NYHA I - II - III	O_2 if NYHA III or PHT
Congenital heart disease / NYHA I - II - III	O_2 if NYHA III or PHT or PaO_2 < 70 mmHg
ICD / NYHA I - II	1 month post-ICD therapy associated with presyncope or syncope

9.11/ CARDIOVASCULAR COMPLICATIONS OF SYSTEMIC DISEASES

HIV

Heart failure - Dilated cardiomyopathy - Myocarditis; Pericardial effusion / Pericarditis; Infective and noninfective endocarditis (non-bacterial thrombotic endocarditis); PHT; Neoplasia → Kaposi sarcoma (epicardial) / NHL; Accelerated atherosclerosis / Endothelial dysfunction; Early-onset cerebrovascular disease; Protease inhibitors → lipodystrophy / ↗ TG - ↗ LDL - ↘ HDL / Glucose intolerance; Arrhythmias - ↗ QT; Dysautonomia; Vasculitis; Drug interactions

VASCULITIS

TAKAYASU - GIANT CELL ARTERITIS - BEHÇET: ▸▸| Chapter 8

KAWASAKI: young children (< 5 years); fever; rash; conjunctivitis; lymphadenopathy; mucosal lesions; erythema of extremities then desquamation

- **Cardiac involvement**: pericardial effusion; myocarditis; MI; aortitis; AR; heart failure; arrhythmias; coronary arteritis
- **Coronary artery stenoses or aneurysms:** < 6 weeks after onset of the disease; proximal lesions; short-term, medium-term and long-term risk of thrombosis
- **Treatment:** ASA; IV Ig; consider anticoagulation if multiple aneurysms or thrombus

CHURG & STRAUSS: pericarditis; myocarditis; coronary arteritis; heart failure; mesenteric ischemia

POLYARTERITIS NODOSA (MEDIUM VESSEL VASCULITIS): HTN; heart failure; arteritis; coronary aneurysms; angina; myocardial infarction; pericarditis

CONNECTIVE TISSUE DISEASES

RHEUMATOID ARTHRITIS: pericarditis; pericardial effusion; constriction; accelerated CAD; blocks (rheumatoid nodules); granulomatous valve lesions with regurgitation (mitral; aortic); rheumatoid aortitis; PHT (rheumatoid lung disease)

HLA-B27-ASSOCIATED SPONDYLOARTHROPATHIES: aortitis / aortic root dilatation; aortic valvulitis; AR; blocks; early CAD

SYSTEMIC LUPUS ERYTHEMATOSUS: pericarditis; pericardial effusion; constrictive pericarditis; coronary arteritis; accelerated CAD; nonbacterial endocarditis (Libman-Sacks; nonmobile vegetations); valvulitis (fibrosis; retraction; regurgitation); myocarditis; sinus tachycardia; congenital AV block; PHT; aortitis

- **Drug-induced lupus**: hydralazine; procaïnamide; quinidine
- **Antiphospholipid syndrome (antiphospholipid antibodies or lupus anticoagulant)**: arterial or venous thrombosis; myocardial infarction; stroke; intracardiac thrombus; PHT; nonbacterial endocarditis; valvulitis (fibrosis; regurgitation)

SCLERODERMA: Raynaud; renal crisis; pericarditis; pericardial effusion; microvascular ischemia; myocardial fibrosis; heart failure (diastolic > systolic); conduction disorders; PHT

POLYMYOSITIS: myocarditis / heart failure; blocks; PHT

ENDOCRINE DISEASES

ACROMEGALY: HTN; LVH; heart failure; diastolic dysfunction; stroke; insulin resistance; aortic root dilatation; mitral regurgitation

CUSHING'S DISEASE: Accelerated CAD; hyperglycemia / insulin resistance; dyslipidemia; HTN; LVH; heart failure; dilated cardiomyopathy; stroke; PAD

HYPERPARATHYROIDISM: ↗ contractility; short QT; calcifications (valvular; aortic)

HYPOCALCEMIA: Prolonged QT; ↘ contractility

HYPERTHYROIDISM: high output; ↘ systemic resistance; systolic HTN (↗ pulse pressure); sinus tachycardia; ↗ plasma volume; angina (↗ O_2 demand); vasospasm; PHT; AF; heart failure

HYPOTHYROIDISM: low output state; ↗ systemic resistance; sinus bradycardia; diastolic HTN; ↗ LDL; hypertriglyceridemia; pericardial effusion; prolonged QT; low voltage; ↗ risk of CAD; diastolic dysfunction

PHEOCHROMOCYTOMA: HTN; tachycardia; concentric LVH; myocarditis; cardiomyopathy similar to Takotsubo

MUSCULAR DYSTROPHIES

PERMANENT PACEMAKER: **A)** Third-degree or advanced second-degree AV block (class I recommendation); **B)** May be considered with any degree of AV block (including first degree) in patients with Steinert disease, Kearns-Sayre syndrome or limb-girdle muscular dystrophy (class IIb)

BECKER DYSTROPHY AND DUCHENNE DYSTROPHY: X-linked; ↗ CK; **progressive dilated cardiomyopathy**; MR; hypertrabeculations; arrhythmias; blocks

- **Duchenne**: **prominent R wave in V1** (↗ R/S ratio); Q wave in left precordials; short PR; RVH

MYOTONIC DYSTROPHY: autosomal dominant; **predominantly affects conduction tissue**; blocks; arrhythmias (AF; flutter; VT; bundle branch reentry VT); systolic and/or diastolic dysfunction; LVH; MVP

› **Follow-up**: Annual ECG and Holter

EMERY-DREIFUSS DYSTROPHY: DCM; arrhythmias (AF; Flutter; atrial asystole with junctional rhythm; VT; VF); conduction disorders (including dystrophy secondary to **lamin A/C** mutation)

LIMB-GIRDLE MUSCULAR DYSTROPHY: **DCM**; prominent R wave in V1; blocks

OTHER NEUROLOGICAL DISEASES

FRIEDREICH'S ATAXIA: autosomal recessive; **concentric HCM** (sometimes localized in the septum); LVOT obstruction; diffuse T wave inversion; possible progression to DCM

MITOCHONDRIAL DISEASES: HCM; DCM; blocks (Kearns-Sayre syndrome); preexcitation

DESMIN-RELATED MYOPATHY: autosomal dominant; conduction disorders; DCM; RCM

GUILLAIN-BARRÉ SYNDROME: HTN; OH; sinus tachycardia; ST abnormalities; tachyarrhythmias / bradyarrhythmias; asystole

MYASTHENIA GRAVIS: myocarditis; arrhythmias; blocks

ACUTE CEREBROVASCULAR DISEASE: ST elevation or depression; T wave inversion; Q waves; ↗ QT (with peaked T wave); neurogenic stunned myocardium; Takotsubo cardiomyopathy; systolic dysfunction; acute pulmonary edema; VT - VF; Torsade de pointes; bradyarrhythmias

CHRONIC RENAL DISEASE

INDEPENDENT CARDIOVASCULAR RISK FACTOR

Accelerated and aggressive CAD; cardiomyopathy; LVH; HTN; valvular heart disease (Ao sclerosis; MAC); vascular calcifications; toxicity of cardiovascular drugs; dyslipidemia (↘ HDL; ↗ TG - ↗ LDL); cardiorenal syndrome; arrhythmias; blocks; infective endocarditis; anemia associated with heart failure; risk of contrast nephropathy; inflammatory state

› To convert serum creatine level mg/dL to mmol/L, multiply by 88.4

› **High output heart failure (AV fistula)**: Nicoladoni - Branham sign → ↘ cardiac output (↘ LVOT VTI) after manual compression of the fistula; predictive improved cardiac output after fistula ligation

9.12/ CARDIOVASCULAR COMPLICATIONS OF TRAUMA

PENETRATING INJURY: knife; bullet

› Tamponade; Ischemia (coronary trauma); Complex lesion (valves; coronary arteries; intracardiac fistula)

NONPENETRATING INJURY: compression or deceleration or contusion; safety belt; airbag; steering wheel; fall; collision; rib fractures; CPR

› Contusion; systolic dysfunction; LV free wall rupture (tamponade or hemothorax); RA rupture; ventricular septal rupture; ruptured chordae tendineae or papillary muscle; ruptured valve leaflet (Ao > M > T); Ao rupture; rupture of pericardium (cardiac hernia); arrhythmias; blocks; myocardial infarction (thrombosis; dissection; coronary laceration); *commotio cordis*

SEVERE BURN: toxic myocardial depression for several days (in addition to significant hypovolemia)

ELECTROCUTION: cardiac arrest (VF; asystole); myocardial necrosis; ischemia; arrhythmias; conduction disorder; ECG abnormalities; dysautonomia

MANAGEMENT

ABC; ACLS; Cardiac monitor; NS Bolus; Transfusion; Ultrasound (FAST); OR - Urgent left anterolateral thoracotomy in the case of structural damage

9.13/ POISONING

COCAINE POISONING

SYMPATHOMIMETIC AGENT: inhibition of presynaptic reuptake of norepinephrine and dopamine

CARDIOVASCULAR COMPLICATIONS: sympathetic stimulation; HTN; LVH; ischemia; MI; DCM (excess catecholamines); myocarditis; heart failure (systolic and/or diastolic); arrhythmia; sudden death; endocarditis; aortic dissection; stroke - intracranial hemorrhage; Takotsubo; Brugada pattern on ECG; ↗ QT (effect on sodium and potassium channels)

MYOCARDIAL INFARCTION: ↗ O_2 demand; vasospasm; accelerated CAD; thrombosis (↗ platelet activation / aggregation); ↗ plaque rupture; coronary dissection

- **Treatment of myocardial infarction:** O_2; ASA; Benzodiazepines; Nitrates; CCB (Diltiazem 20 mg IV); Coronary angiography if persistent ST elevation (thrombolysis if coronary angiography not available and in the absence of contraindication); avoid BB (unopposed alpha-adrenergic stimulation)

BETA-BLOCKER POISONING

PRESENTATION: Symptoms often appear within first 6 h after ingestion: bradycardia; hypotension; cardiogenic shock; altered LOC; seizures; hypoglycemia; bronchospasm

ASSESSMENT: ECG; Glucose; Electrolytes; Ca^{2+}; BUN; Creatinine; Acetaminophen - Salicylate; beta-HCG

- **ECG**: sinus bradycardia; ↗ PR interval; ↗ QRS interval (Propranolol or Acebutolol); bradyarrhythmia; asystole

MANAGEMENT: ABC; Monitor; Atropine (0.5-1 mg IV every 3-5 min up to 0.04 mg/kg); Bolus NS; IV Dextrose; Benzodiazepine if seizures; Activated charcoal (50 g) if patient presents 1-2 h postingestion; Poison Center

IF NECESSARY (IN THE FOLLOWING ORDER)

a) **Glucagon:** IV bolus 5 mg over 1 min (± 2nd bolus in 10 min); if improvement → start infusion (2-5 mg/h); target MAP 60 mmHg; Antinausea treatment (Ondansetron)
b) **IV Calcium:** Calcium chloride (1 g of 10% solution = 10 mL via central line up to a dose of 3 g if necessary) or Calcium gluconate (30 mL of a 10% solution via a central or peripheral line); Monitoring of serum calcium
c) **Vasopressors:** Epinephrine (1-10 µg/min; titrate to achieve MAP of 60 mmHg)
d) **High-dose insulin / Glucose (D5-10%) infusion;** ▶▶| CCB poisoning; K^+ - Mg^{2+} supplement PRN
e) **IV fat emulsion** (parenteral nutrition)
f) **Sodium bicarbonate** (1-2 mEq/kg IV ± infusion) if ↗ QRS interval
g) **Endovenous pacemaker:** frequent capture failure; only slight hemodynamic improvement; consider if failure of drug treatment
h) **IABP / Ventricular assist device** if failure of drug treatment
i) **Consider hemodialysis** if failure of drug treatment (Atenolol; Nadolol; Sotalol; Acebutolol)

CALCIUM CHANNEL BLOCKER POISONING

DIHYDROPYRIDINE CCB: arterial vasodilatation; reflex tachycardia; effects of nondihydropyridine CCB with high-dose ingestion

NONDIHYDROPYRIDINE CCB: peripheral vasodilatation; bradycardia; negative inotropic agent

ASSESSMENT: ECG; Glucose; Electrolytes; Ca^{2+}; BUN; Creatinine; Acetaminophen - Salicylate; beta-HCG

MANAGEMENT: ABC; Monitor; Bolus NS; Atropine (0.5-1 mg IV every 2-3 min up to 3 mg); activated charcoal (50 g) if patient presents in 1-2 h post-ingestion; Poison Center

IV CALCIUM: Calcium chloride (10-20 mL of solution 10% x 10 min via central line; repeat up to 4 x if necessary every 20 min) or Calcium gluconate (30 to 60 mL of a 10% solution via a central or peripheral line); Monitoring of serum calcium

- **Infusion**: Calcium chloride (0.2-0.4 mL/kg/h of a 10% solution) or Calcium gluconate (0.6-1.2 mL/kg/h of a 10% solution) if necessary; serum ionized calcium assay every 2 hours; ECG monitoring

IF NECESSARY (IN THE FOLLOWING ORDER)

a) Glucagon: IV bolus 5 mg over 1 min (± 2nd and 3rd boluses every 10 min); if improvement → start infusion (2-15 mg/h); target MAP 60 mmHg; Antinausea treatment (Ondansetron)

b) High-dose insulin / Glucose infusion; 50 mL D50% if blood glucose < 8.25 mmol/L; Correct potassium

- **Bolus:** 1 unit/kg of regular insulin IV
- **Infusion:** 0.5 U/kg/h IV (titrate up to 2 U/kg/h according to response; increase by 0.5 U/kg/h every 20 min)
  - **D5-10% infusion**: 0.5-1 g/kg/h of dextrose; additional bolus of D50% PRN (capillary blood glucose **every 15-30 min)**
  - **Serum potassium** assay every 30 min (± Mg^{2+}); supplement as necessary

c) IV vasopressor: IV Norepinephrine

d) IV fat emulsion (parenteral nutrition): bolus 1-1.5 mL/kg x 1 min (20% solution); Infusion 0.25-0.5 mL/kg/min (30-60 min)

e) Other measures: Endovenous pacemaker (but does not improve contractility); IABP - Ventricular assist device

DIGOXIN POISONING

EXTRACARDIAC MANIFESTATIONS: visual disorders; GI symptoms (nausea; vomiting); neurological symptoms (confusion; muscle weakness); hyperkalemia

CARDIAC MANIFESTATIONS: sinus bradycardia; sinus arrest; ectopic atrial tachycardia with AV block; "regularized" AF (junctional escape rhythm); junctional tachycardia; AV block; PVCs; ventricular bigeminy; VT; bidirectional VT; VF

- **Mechanisms**: **A)** ↗ **Delayed after-depolarizations** (due to ↗ intracellular Ca^{2+}); **B)** ↗ **Automaticity; C)** ↗ Vagal tone; **D)** Associated hyperkalemia
- **Digoxin impregnation**: flattening / inversion of T waves; ↘ QT; "scooped" ST segment; ST depression (lateral leads); U waves

ASSESSMENT: Plasma digoxin (6 h post-ingestion if acute poisoning); electrolytes; K+; Mg^{2+}; Creatinine - BUN; ECG; Blood glucose

MANAGEMENT: ABC; Cardiac monitoring; Poison Center; Atropine 0.5 mg IV; Bolus NS; Activated charcoal if poisoning < 1-2 h

CORRECT HYPOKALEMIA: as hypokalemia exacerbates the toxic effects; correct hypomagnesemia associated with hypokalemia

- **Do not correct hyperkalemia,** which is corrected by Digibind

ANTIDOTE: Digibind (anti-Digoxin antibody)

- **Indications: A)** Threatening arrhythmia (symptomatic bradycardia; AV block; ventricular arrhythmia; asystole); **B)** Target organ damage (ARF; altered state of consciousness); **C)** Hyperkalemia (> 5 - 5.5 mmol/L)
- **1 vial of Digibind neutralizes 0.5 mg of Digoxin**

EMPIRICAL TREATMENT (ACUTE POISONING WITH UNKNOWN DOSE)	ACUTE POISONING WITH KNOWN INGESTED DOSE	CHRONIC POISONING WITH KNOWN PLASMA DIGOXIN
10 vials (repeat in 30 min if insufficient)	Number of vials = [Ingested dose of Digoxin (mg) x 0.8] / 0.5	Number of vials = [Serum concentration (ng/mL) x patient's weight (kg)] / 100

MAINTAIN ON MONITOR > 72 H if concomitant renal failure (delayed elimination)

HEMODIALYSIS: not indicated

9.14/ SWAN-GANZ CATHETER PLACEMENT

INDICATIONS: A) Cardiogenic shock; **B)** Mixed shock; **C)** Mechanical complication of myocardial infarction; **D)** PHT; **E)** Pretransplantation assessment

1) VERIFICATIONS: patency of ports; test balloon and pressure transducer

2) CENTRAL VENOUS ACCESS: insert the introducer (Cordis) under ultrasound guidance into the internal jugular vein (modified Seldinger technique)

3) SWAN-GANZ CATHETER PLACEMENT: insert the Swan-Ganz catheter by following the natural curvature towards the PA

- Inflate the balloon in the RA (RA hemodynamic curve); keep the balloon inflated while advancing the Swan-Ganz (deflate the balloon on withdrawal)
- Advance the Swan-Ganz while examining changes in the appearance of the hemodynamic curve displayed on the monitor (RA → RV → PA → Wedge)

RA	RV	PA
15-20 cm	**30 cm**	**40 cm**

- Withdraw the Swan-Ganz if **< 1 mL of NS** is necessary to inflate the balloon and obtain a Wedge pressure (the catheter tip is probably too distal)

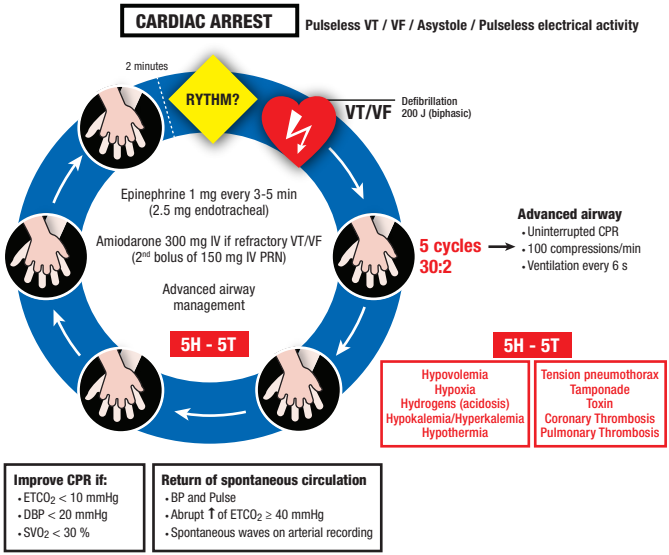
4) CXR: catheter tip < 5 cm from the midline; West zone # 3 preferable

CONSIDER FLUOROSCOPY if chamber dilatation or significant TR

AIR EMBOLISM: left lateral decubitus position (to prevent RVOT obstruction); 100% O_2

9.15/ CARDIOPULMONARY RESUSCITATION

CARDIOPULMONARY ARREST



RECOGNIZE CARDIOPULMONARY ARREST: unresponsive / breathing / pulse

› **Activate the survival chain:** 911 - Blue Code - Defibrillator / AED

CARDIOPULMONARY RESUSCITATION

› **Cycles: 30 compressions : 2 ventilations**

› **Compressions**: lower half of the sternum; 100-120 compressions / min; 5 cm deep (avoid > 6 cm); complete chest recoil between each compression; minimize interruptions

› **Ventilation**: Head tilt / Chin lift ("Jaw thrust" if cervical trauma); avoid excessive ventilation

DEFIBRILLATION: Pulseless VT or VF; perform as rapidly as possible

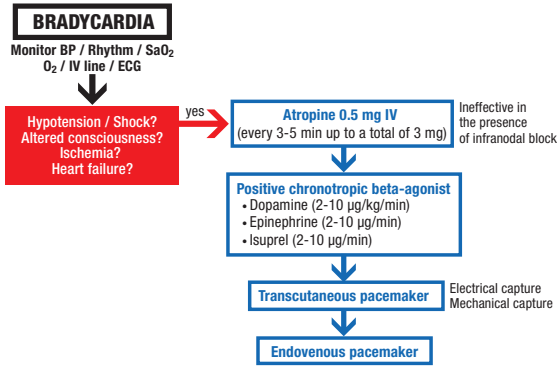
AIRWAY MANAGEMENT

› **Initial ventilation**: Ambu mask; 1 s; elevation of the rib cage; avoid excessive ventilation

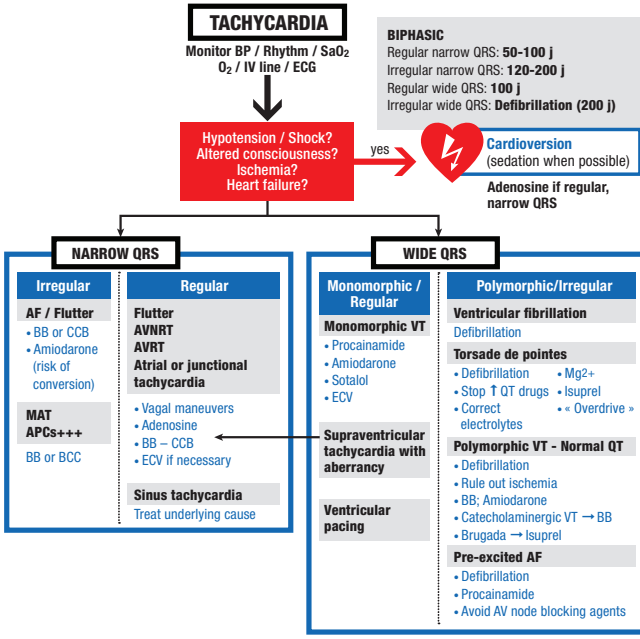
› **Advanced airways support**: allows better ventilation and protects the airways; Endotracheal tube or Laryngeal mask or Combitube

- **Confirmation of position: A)** Physical examination (expansion of rib cage; auscultation); **B)** Capnography / CO_2 detector; **C)** Esophageal detector (syringe); **D)** CXR (distal extremity of ETT > 3 cm from the carina)
- **CPR cycles**: **Continuous compressions at 100 bpm; Asynchronous ventilation every 6 sec**

BRADYCARDIA



TACHYCARDIA



DRUGS USED IN CARDIOPULMONARY RESUSCITATION

Adenosine	• 6 mg IV (push) then 20 mL NS • 2nd bolus 12 mg IV PRN	• Supraventricular tachycardia	Bronchospasm; Hypotension; Flushing; Retrosternal chest pain; Can trigger AF
Amiodarone	• 150 mg IV x 10 min (repeat PRN) • Infusion: 1 mg/min x 6 h then 0.5 mg/min (dilution: 450 mg / 250 mL D5%) • Max: 2.2 g / 24 h	• Supraventricular tachycardia • Stable monomorphic VT • Polymorphic VT with normal QT	Bradycardia; ↗ QT; Long-term toxicity
Beta-blockers	• **Esmolol:** 0.5 mg/kg x 1 min then infusion of 0.05-0.3 mg/kg/min (dilution: 2500 mg / 250 mL) • **Metoprolol**: 5 mg IV x 1 min (repeat every 5 min up to a total of 15 mg)	• Supraventricular tachycardia • Polymorphic VT associated with ischemia or LQTS or catecholaminergic VT	Hypotension: Bradycardia; Negative inotrope; Bronchospasm
Diltiazem	• 15-20 mg IV x 2 min • 2nd bolus (in 15 min): 20-25 mg IV • Infusion: 5-15 mg/h IV • Dilution: 125 mg/100 mL D5 % (= 1 mg/mL)	• Supraventricular tachycardia	Hypotension; Bradycardia; Negative inotrope
Lidocaine	• Bolus: 1-1.5 mg/kg IV • Perfusion: 1-4 mg/min (30-50 µg/kg/min) • Dilution: 2 g / 500 mL D5%	• Stable monomorphic VT	Altered state of consciousness; Seizures; Bradycardia
Procainamide	• 20-50 mg/min (until suppression of arrhythmia or hypotension or ↗ QRS > 50% or total dose 17 mg/kg) • Dilution: 1000 mg / 250 mL NS	• Pre-excited AF • Stable monomorphic VT	Bradycardia; Hypotension; ↗ QT; Torsade de pointes; Avoid in the presence of heart failure
Sotalol	• 1.5 mg/kg IV x 5 min	• Stable monomorphic VT	Bradycardia; Hypotension; ↗ QT; Torsade de pointes; Avoid in the presence of heart failure
Magnesium sulfate	• 1-2 g IV x 15 min	• Polymorphic VT with ↗ QT	Hypotension; Respiratory depression
Epinephrine	• **Dose**: 0.1-0.5 µg/kg/min • **Dilution:** 5 mg / 250 mL D5%		

Dobutamine	• **Dose**: 2-20 µg/kg/min • **Dilution:** 250 mg / 100 mL D5%
Dopamine	• **Dose**: 1-20 µg/kg/min • **Dilution:** 400 mg / 250 mL D5%
Isuprel	• **Dose**: 0.5-10 µg/min • **Dilution:** 1 mg / 250 mL D5%
Milrinone	• **Bolus**: 50 µg/kg x 10 min • **Dose**: 0.375 to 0.75 µg/kg/min • **Dilution:** 10 mg / 100 mL D5% (= 0.09 mg/mL) or 20 mg / 100 mL D5% (= 0.17 mg/mL)
Norepinephrine	• **Dose**: 0.1-0.5 µg/kg/min • **Dilution:** 4 mg / 250 mL D5% (double PRN)
Phenylephrine	• **Dose**: 0.5-2 µg/kg/min • **Dilution:** 10 mg / 250 mL NS

MANAGEMENT POST-CARDIAC ARREST

Look for and treat the cause of the cardiac arrest; Coronary angiography if necessary

VENTILATION: Tidal volume 6-8 mL/kg; $SaO_2 \geq 94\%$; $PaCO_2$ 40-45 mmHg

TARGET ORGAN PERFUSION: NaCl bolus; vasopressors (Epinephrine; Dopamine; Norepinephrine); treat any reversible causes; IABP - Ventricular assist device

- Stunned myocardium x 24-48 h and transient SIRS post-cardiac arrest
- **Targets:** SBP ≥ 90 mmHg; MAP ≥ 65 mmHg; $SVO_2 \geq 70$ %

TARGETED TEMPERATURE MANAGEMENT

- **Indications**: Comatose adult patients (no meaningful response to verbal commands) with return of spontaneous circulation after cardiac arrest
- **Benefits**: improvement of survival and neurological prognosis (★ Hypothermia after cardiac arrest study group)
- **Targets**: uncertain (between 32°C to 36°C for at least 24 h); intensive treatment of hyperthermia; ★ TTM → no demonstrated benefit of 33°C versus 36°C
- **Complications**: coagulopathy; arrhythmias; ↗ QT; bradycardias; hyperglycemia; infectious risk; hypokalemia / hypomagnesemia / hypophosphatemia

NEUROLOGICAL ASSESSMENT: neurological examination; EEG (rule out seizures in the presence of persistent coma); Brain CT / MRI

- **Factors of poor prognosis (valid after > 72 h)**: **A)** Bilaterally absent pupillary light reflex; bilaterally absent corneal reflexes; **B)** Status myoclonus (during the first 72 hours); **C)** EEG with persistent absence of reactivity to external stimuli or with persistent burst supression or with intractable status epilepticus; **D)** Somatosensory evoked potentials (bilateral absence of cortical response to median nerve stimulation); **E)** Imaging (extensive cortical / subcortical lesions; extensive brain edema)
- **Brain death**: consider organ donation

Abbreviations

A

AAD: Antiarrhythmic drug
AAA: Abdominal aortic aneurysm
ABC: Airway, Breathing, Circulation
ABI: Ankle-Brachial Index
A/C: Anticoagulant / Anticoagulation
ACEi: Angiotensin-converting enzyme inhibitor
ACLS: Advanced Cardiac Life Support
ACS: Acute coronary syndrome
AF: Atrial fibrillation
AIVR: Accelerated idioventricular rhythm
ALT: Alanine aminotransferase
AML: Anterior mitral leaflet
ANA: Antinuclear antibody
Ao: Aorta
APC: Atrial premature complex
Apo: Apoliprotein
aPTT: Activated partial thromboplastin time
AR: Aortic regurgitation
ARB: Angiotensin receptor blocker
ARDS: Adult respiratory distress syndrome
ARF: Acute renal failure
ARVD: Arrhythmogenic right ventricular dysplasia
AS: Aortic stenosis
ASA: Acetylsalicylic acid
ASD: Atrial septal defect
AST: Aspartate aminotransferase
ATL: Anterior tricuspid leaflet
AV: Atrioventricular
AVM: Arteriovenous malformation
AVNRT: Atrioventricular nodal reentrant tachycardia
AVR: Aortic valve replacement
AVRT: Atrioventricular reentry tachycardia

B

BB: Beta-blockers
BID: Twice daily
BMI: Body mass index
BMS: Bare metal stent
BNP: Natriuretic peptide type B
BOOP: Bronchiolitis obliterans organizing pneumonia
BP: Blood pressure
BSA: Body surface area
BUN: Blood urea nitrogen
BVR: Balloon Valvuloplasty Registry

C

CABG: Coronary artery bypass graft
CAD: Coronary artery disease
CBC: Complete blood count
CCB: Calcium channel blockers
CCS: Canadian Cardiology Society
CCV: Chemical cardioversion
CK: Creatinine kinase
CM: Cardiomyopathy
CML: Chronic myeloid leukemia
CNS: Central nervous system
CO: Cardiac output
CoA: Coarctation of the aorta
CoNS: Coagulase-negative Staphylococcus
COPD: Chronic obstructive pulmonary disease
COX-1: Cyclooxygenase-1
CPB: Cardiopulmonary bypass
CRF: Chronic renal failure
CRP: C-reactive protein
CRT: Cardiac resynchronization therapy
CS: Coronary sinus
CSNRT: Corrected Sinus Node Recovery Time
CT: Computed tomography
cTn: Cardiac troponin
cTnT HS: Highly sensitive cardiac troponin T
cTnT: Cardiac troponin T
CTO: Chronic total occlusion
CVP: Central venous pressure
CXR: Chest x-ray

D

DBP: Diastolic blood pressure
DCM: Dilated cardiomyopathy
DDx: Differential diagnosis
DES: Drug-eluting stent
DIC: Disseminated intravascular coagulation
DM: Diabetes
dP/dt: Rate of LV pressure rise in early systole
DTS: Duke Treadmill score
DVT: Deep vein thrombosis

E

ECG: Electrocardiogram
ECMO: Extracorporeal membrane oxygenation
ECV: Electrical cardioversion
EEG: Electroencephalogram
EOA: Effective orifice area
EPO: Erythropoietin
EPS: Electrophysiological study
ESR: Erythrocyte sedimentation rate
EVAR: Endovascular aortic repair

F

FAC: Fractional Area Change

FFP: Fresh frozen plasma
FFR: Fractional flow reserve
FMD: Fibromuscular dysplasia

G

GERD: Gastroesophageal reflux disease
GFR: Glomerular filtration rate
GI: Gastrointestinal

H

HbA1c: Glycosylated hemoglobin
HCM: Hypertrophic cardiomyopathy
HDCT: High-definition computed tomography
HDL: High-density lipoprotein
HELLP: HELLP syndrome
HIT: Heparin-induced thrombocytopenia
HR: Heart rate
HSM: Hepatosplenomegaly
HTN: Hypertension

I

IABP: Intra-aortic balloon pump
IART: Intraatrial reentry tachycardia
ICD: Implantable cardioverter-defibrillator
IDU: Intravenous drug user
IMT: Intima-media thickness
INR: International normalized ratio
ISA: Intrinsic sympathetic activity
IUGR: Intrauterine growth retardation
IVC: Inferior vena cava
IVCT: Isovolumic contraction time
IVRT: Isovolumic relaxation time
IVS: Interventricular septum
IVUS: Intravascular ultrasound

J

JVD: Jugular vein distension

L

LA: Left atrium
LAA: Left atrial appendage
LAD: Left anterior descending
LAH: Left atrial hypertrophy
LAHB: Left anterior hemiblock
LAO: Left anterior oblique
LBBB: Left bundle branch block
LMCA: Left main coronary artery
LDH: Lactate dehydrogenase
LDL: Low-density lipoprotein
LFTs: Liver function tests
LGE: Late gadolinium enhancement
LIMA: Left internal mammary artery
LMWH: Low molecular weight heparin
LPHB: left posterior hemiblock
LPL: Lipoprotein lipase
LQTS: Long QT syndrome
LV: Left ventricle
LVAD: Left ventricular assist device
LVDD: Left ventricular diastolic diameter
LVEDP: Left ventricular end-diastolic pressure
LVEF: Left ventricular ejection fraction
LVH: Left ventricular hypertrophy
LVOT: Left ventricular outflow tract
LVSD: Left ventricular systolic diameter

M

M: Mitral
MAC: Mitral annular calcification
MAO inhibitor: Monoamine oxidase inhibitor
MAP: Mean arterial pressure
MCP: Metacarpophalangeal
MET: Metabolic Equivalent of Task
MIBIP: MIBI-Dipyridamole
MPA: Main pulmonary artery
MR: Mitral regurgitation
MS: Mitral stenosis
MSK: Musculoskeletal
MTX: Methotrexate
MVP: Mitral valve prolapse
MVR: Mitral valve replacement

N

NGT: Nasogastric tube
NIHSS: NIH Stroke Scale
NNT: Number needed to treat
NPO: Nil per os
NPV: Negative predictive value
NSAID: Non-steroidal anti-inflammatory drug
NSVT: Non-Sustained Ventricular Tachycardia
NYHA: New York Heart Association

O

OH: Orthostatic hypotension
OR: Operating room
OSAHS: Obstructive sleep apnea / hypopnea syndrome
OTP: Orthopnea

P

PA: Pulmonary artery
PAD: Peripheral artery disease
PAH: Pulmonary arterial hypertension
PAN: Polyarteritis nodosa
PAP: Pulmonary artery pressure
PAT: Paroxysmal atrial tachycardia
PCI: Percutaneous coronary intervention
PCR: Polymerase chain reaction
PDE-5: Phosphodiesterase-5
PET: Positron emission tomography
PET-FDG: Fluorodeoxy-glucose positron emission tomography
PFO: Patent foramen ovale
PFTs: Pulmonary function tests
PHT: Pressure half time
PHT: Pulmonary hypertension
PISA: Proximal isovolumic surface area
PDA: Posterior interventricular artery
PJRT: Paroxysmal junctional reentry tachycardia
PLAX: Parasternal long axis
PML: Posterior mitral leaflet
PMR: Polymyalgia rheumatica
PMT: Pacemaker-mediated tachycardia
PNC: Penicillin
PND: Paroxysmal nocturnal dyspnea
PO: Per os
POTS: Postural orthostatic tachycardia syndrome
PPD: Purified Protein Derivative (Mantoux test)
PPI: Proton pump inhibitor
PPM: Permanent pacemaker
PPV: Positive predictive value
PR: Pulmonary regurgitation
PRN: As needed
PS: Pulmonary stenosis
PSAX: Parasternal short axis
PSVT: Paroxysmal supraventricular tachycardia
PT: Prothrombin time
PTCA: Percutaneous coronary angioplasty
PTL: Posterior tricuspid leaflet
PTU: Propylthiouracil
PV: Pulmonary vein
PVAB: Post-ventricular atrial blanking
PVARP: Post-ventricular atrial refractory period
PVE: Prosthetic valve endocarditis
PVR: Pulmonary valve replacement
PVR: Pulmonary vascular resistance

Q

QD: Once daily
QID: Four times a day

R

RA: Rheumatoid arthritis
RA: Right atrium
RAA: Right atrial appendage
RAH: Right atrial hypertrophy
RAO: Right anterior oblique
RBBB: Right bundle branch block
RCA: Right coronary artery
RCM: Restrictive cardiomyopathy
RCT: Randomized controlled trial
RF: Radiofrequency
RF: Rheumatoid factor
RF: Risk factor
RPA: Right pulmonary artery
RUQ: Right upper quadrant
RV: Right ventricle
RVAD: Right ventricular assist device
RVG: Radionuclide ventriculography
RVH: Right ventricular hypertrophy
RVOT: Right ventricular outflow tract
RVSP: Right ventricular systolic pressure
RWMA: Regional wall motion abnormality
RWT: Relative wall thickness

S

SA: Sinoatrial
SAECG: Signal-averaged ECG
SAH: Subarachnoid hemorrhage
SAM: Systolic anterior movement of mitral leaflet
SaO_2: Oxygen saturation
SBP: Systolic blood pressure
SIRS: Systemic inflammatory response syndrome
SLE: Systemic lupus erythematosus
SPEP: Serum protein electrophoresis
SQTS: Short QT syndrome
SR: Sinus rhythm
SSRI: Selective serotonin reuptake inhibitor
SSS: Sick sinus syndrome
STS: Society of Thoracic Surgeons
STEMI: ST segment elevation myocardial infarction
STL: Septal tricuspid leaflet
SVC: Superior vena cava

SVO_2: Venous oxygen saturation
SVR: Systemic vascular resistance

T

T: Tricuspid
TARP: Total atrial refractory period
TAVI: Transcatheter aortic valve implantation
TB: Tuberculosis
TEE: Transesophageal echocardiography
TG: Triglycerides
TGV: Transposition of the great arteries
TIA: Transient ischemic attack
TID: Three times a day
TNK: Tenecteplase
TNT: Nitroglycerin
TOF: Tetralogy of Fallot
TR: Tricuspid regurgitation
TTE: Transthoracic echocardiography
TTR: Transthyretin
TVR: Tricuspid valve replacement
TXA-2: Thromboxane-2

U

ULN: Upper limit of normal
URI: Upper rate interval
URTI: Upper respiratory tract infection
US: Ultrasound

V

VAC: Vacuum assisted closure
VF: Ventricular fibrillation
VLDL: Very low density lipoprotein
VO_2: Oxygen consumption
VPC: Ventricular premature complex
VSD: Ventricular septal defect
VT: Ventricular tachycardia
VTI: Velocity-time integral
vW: von Willebrand

W

WMSI: Wall motion score index
WPW: Wolff-Parkinson-White

★ Clinical Trials cited

4D (statins in dialysis)..... 322
4S (statins)..... 322
AATAC-AF (PVI in congestive HF)..... 122; 215
ACAS (carotid revascularization)..... 294
ACCEPT-D (ASA in DM)... 332
ACCOMPLISH (HTN)..... 326
ACCORD (fibrates)..... 321
ACCORD (glycemic control)..... 330
ACCORD-BP (BP control in DM)..... 332
ACST (carotid revascularization)..... 294
ACT (N-acetyl-L-cysteine)...48
ACT (Vernakalant)..... 213
ACTION (Nifedipine)..... 77
ACTIVE-A (Clopidogrel)... 216
ACUITY (Bivalirudin)..... 87
ADVANCE (glycemic control)..... 330
ADVANCE (Perindopril and DM)..... 332
AFASAK 1 and 2 (Warfarin)..... 216
AFCAPS / TexCAPS (statins)..... 322
AF-CHF (AF).....122, 211
AFFIRM (AF)..... 211
A-HEFT (Hydralazine - Nitrate)..... 121
AIM-HIGH (Niacin) ..321, 322
AIRE (ACE Inhibitors - Ramipril).....96, 118
ALLHAT (HTN)..... 326
ALLIANCE (statins)..... 322
AMPLIFY (Apixaban in venous thromboembolism)..... 299
ANDROMEDA (Dronedarone)...121, 212, 231
Antithrombotic Trialists' (ASA).....76, 86, 96, 287, 314, 315
APAF (AF)..... 211
ARISTOTLE (Apixaban in AF)..... 217
ARMYDA (statins)..... 106
ARMYDA-2 (Clopidogrel)..106
ARTS (CABG / PCI)..... 79
ASCEND (ASA in DM)..... 331
ASCEND-HF (Nesiritide) . 128
ASCOT-BP (HTN)..... 326
ASCOT (statins)..... 322
ASPIRE (ASA in venous thromboembolism)..... 299
ASSERT (AF detected by pacemaker)..... 219
ASSET (thrombolysis)..... 93
ASSOCIATE (Ivabradine)... 77
ATHENA (Dronedarone).....212, 231
ATLAS (Lisinopril)..... 118
ATLAS ACS (Rivaroxaban in ACS)..... 87
A-to-Z (statins)..... 322
AURORA (statins in dialysis)..... 322
AVERROES (Apixaban in AF)..... 217
AVID (ICD)..... 241
AVRO (Vernakalant)..... 213
BAATAF (Warfarin)..... 216
BARI (CABG / PCI)..... 79
BASIL (critical limb ischemia)..... 288
B-CONVINCED (BB)..... 118
BEAT (beta-blockers)..... 118
BEST (CABG / PCI)..... 79
BLOCK-HF (CRT)..... 211
BRIDGE (AF / surgery).... 313
CAFA (Warfarin)..... 216
CAMELOT (Amlodipine) ... 77
CANPAP (OSAHS)..... 123
CAPRICORN (Carvedilol)..... .....96, 118
CAPRIE (Clopidogrel) 76, 287, 315
CARDS (statins in DM).... 332
CARE (statins)..... 322
CARE-HF (CRT)..... .....122, 239, 240
CARESS-HF (ultrafiltration)..... 120
CARESS-in-AMI (pharmaco-invasive strategy)..... 95
CARISA (Ranolazine)..... 77
CARP (preop revascularization)..... 312
CASH (ICD)..... 241
CASS (CABG)..... 79
CAST (post-myocardial infarction PVCs).....102, 121, 212, 230
CHARISMA (Clopidogrel) 287, 315
CHARM (ARB - Candesartan)..... .....96, 120
CHARM-PRESERVED (ARB - Candesartan)..... 124
CHEST (Riociguat in thromboembolic PHT)..... .....305, 306
Cholesterol Treatment Trialists' (statins)..... 322
CIBIS (Bisoprolol)..... 118
CIDS (ICD)..... 241
CLARITY (Clopidogrel)..... 95
CLOSURE-1 (patent foramen ovale)..... 250
CLOT (venous thromboembolism)..... 299
COMET (beta-blockers)... 118
COMMIT (beta-blockers) ... 95
COMMIT (Clopidogrel)..... 95
COMPANION (resynchronization) 122, 239, 240
CONFIRM HF (iron therapy)..... 123
CONSENSUS (ACE inhibitors - Enalapril)..... 118
COPE (Colchicine)..... 174
COPERNICUS (Carvedilol)..... 118
COPPS-POAF (Colchicine)..... 107
CORAL (renovascular disease)..... 289
CORONA (statins in heart failure)..... 322
CORONARY (beating heart surgery)..... 107
CORP (Colchicine)..... 174
COURAGE (CABG / PCI) 79
CREST (stent in carotid stenosis)..... 294
CRYSTAL-AF (Subclinical AF)..... 291
CTAF (antiarrhythmics in AF)..... 212
CTOPP (pacing)..... 233

CTSN (functional mitral regurgitation)..... 123
CTSN AF (Maze during mitral surgery).....151, 215
CURE (Clopidogrel) 86, 96
CURRENT-OASIS (ASA / Clopidogrel)..... 86
DaI-OUTCOMES (Dalcetrapib)..... 322
DANISH (pacing) 233
DANPACE (pacing) 233
DAPT (dual antiplatelet therapy)..... 106
DAVID (pacing) 233, 240
DCCT (glycemic control) . 330
DECREASE-V (preop revascularization)..... 312
DEFINITE (ICD)..... 241
DIAMOND (Dofetilide)..... 231
DIG (Digoxin) 120
DIGAMI (glycemic control) 97
DINAMIT (ICD)..... 241
DOSE (diuretics) 129
DREAM (abdo Ao aneurysm treatment)..... 283
DREAM (thiazolidinediones)..... 330
EAFT (Warfarin in stroke) 294
EARLY-ACS (GPIIb/IIIa inhibitors) 87
EAST (CABG / PCI) 79
ECASS-3 (thrombolysis in stroke)..... 292
ECSS (CABG) 79
ECST (carotid revascularization)..... 294
Eikelboom (Heparin)..... 87
EINSTEIN (Rivaroxaban in VTE)..... 299
EMBRACE (Subclinical AF)..... 291
EMERAS (thrombolysis).... 94
EMPA-REG (Empagliflozin)..... 332
EMPHASIS-HF (Eplerenone) 118
EPHESUS (Eplerenone) 96, 118
ERICA (Ranolazine)..... 77
ESCAPE (Stroke - Revascularization)..... 293
ESPRIT (antiplatelet therapy in stroke)..... 294
ESPS-2 (antiplatelet therapy in stroke)..... 294
EUROPA (ACE inhibitors - Perindopril) 76, 96, 332
EVAR (abdo Ao aneurysm treatment)..... 283
EVEREST (Mitraclip) 154
EVEREST (Tolvaptan)..... 119
EXAMINE (DDP-4 inhibitor)..... 331
EXTRACT-TIMI 25 (Enoxaparin) 95
FAIR-HF (anemia) 123
FAME (FFR) 52, 104
FAME-2 (FFR)..... 52
FREEDOM (CABG / PCI).....79, 333
Freemantle (BB)..... 96
FRISC-II (early invasive strategy)..... 86
GISSI (thrombolysis)..... 93
GISSI-HF (omega-3 or statins in HF) 121, 322
GOPCABE (beating heart surgery) 107
Haïssaguerre (AF)..... 214
HEARMATE II (LVAD)..... 135
HEAT-PPCI (Bivalirudin).... 94
HF-ACTION (exercise).....121, 334
HOPE (ACE inhibitors - Ramipril).....76, 96, 287, 332
HORIZONS-AMI (Bivalirudin) 94
HPS (statins) 322, 332
HPS2-THRIVE (Niacin).....321, 322
Hypothermia after cardiac arrest..... 350
HYVET (HTN in the elderly) 327
IABP-SHOCK (IABP) 99
ICAP (Colchicine)..... 174
ICTUS (ischemia-guided strategy)..... 86
IDEAL (statins)..... 322

INITIATIVE (Ivabradine)..... 77
IONA (Nicorandil)..... 77
I-PRESERVE (ARB - Irbesartan) 124
IRIS (ICD) 241
ISAR-SAFE (double antiplatelet therapy)..... 106
ISCHEMIA (revascularization)..... 123
ISIS-1 (beta-blockers)..... 95
ISIS-2 (thrombolysis) ..93, 95
ISSUE-3 (PPM in vasovagal syncope)..... 228
JUPITER (statins) 318, 322
LATE (thrombolysis)..... 94
LIPID (statins)..... 322
Lyon Diet Heart Study (Mediterranean diet) 338
MADIT-I (ICD) 241, 242
MADIT-II (ICD).121, 241, 242
MADIT-CRT (CRT) 122, 239, 240
MADIT-RIT (ICD - programming)..... 242
MATCH (antiplatelet therapy in stroke)..... 294
MATRIX (Bivalirudin)....87, 94
MERIT-HF (Metoprolol)... 118
MELODY-1 (Macitentan) . 306
MERLIN-TIMI 36 (Ranolazine)..... 77
MIAMI (beta-blockers)..... 95
MOST (pacing)..... 233
MR CLEAN (Stroke - Revascularization)..... 293
MUSTT (ICD) 241, 242
NAPLES II (statins)..... 106
NASCET (carotid stenosis)..... 294
NORDIC-BALTIC (bifurcation)..... 105
NICE-SUGAR (glycemic control)..... 97
NINDS rtPA Stroke Study (thrombolysis in stroke).... 292
NEAT-HFpEF (Nitrates in HFpEF)..... 124
OASIS 5 and 6 (Fondaparinux).....87, 95
ODYSSEY long term (Alirocumab) 322
ONTARGET (Telmisartan)..... 332

OPTIC (Amiodarone) 221
OPTIME-HF (Milrinone)... 128
OSLER (Evolocumab)..... 322
PABA-CHF (AF).....122, 211, 215
PAIN FREE RX II (ATP) ... 242
PALLAS (Dronedarone).....212, 231
PARADIGM-HF (Neprilysin inhibition)..... 121
PARTNER (TAVI) 144
PATENT (Riociguat in PAH)..... 305
PC (patent foramen ovale) 250
PEGASUS (Ticagrelor post MI) 86, 96
PEITHO (pulmonary embolism)..... 298
PEP-CHF (ACE inhibitors - Perindopril) 124
PLATO (Ticagrelor) 86, 94, 96
POISE (periop beta-blockers) 312
Primary Pulmonary Hypertension Study (Epoprostenol)..... 305
PREDIMED (Mediterranean diet)..... 338
PROFESS (antiplatelet therapy in stroke) 294
PROMISE (CCTA vs. Functionnal testing in CAD) 65
PROTECT AF (LAA occlusion) 218, 294
PROVE IT (statins).....96, 322
RACE-II (AF)..... 211
RAFT (CRT).....122, 239, 240
RALES (Spironolactone)... 118
REACT (rescue PCI) 95
RED-HF (anemia in heart failure)..... 123
RELY (Dabigatran in AF).. 217
REMATCH (LVAD)..... 135
REMEDY (Dabigatran in VTE) 299
RESONATE (Dabigatran in VTE) 299
RESPECT (patent foramen ovale)..... 250
RE-VERSE (Idarucizumab)..... 217
RITA-3 (early invasive strategy) 86
ROCKET-AF (Rivaroxaban in AF) 217
ROMICAT-II (coronary CT angiography)..... 66
ROOBY (beating heart surgery)..... 107
ROSE AHF (Nesiritide) 128
SAPPHIRE (revascularization in carotid stenosis) 294
SAVE (ACE inhibitors - Captopril).....96, 118
SAVOR (DPP-4 inhibitor) . 331
SCD-HEFT (ICD) 121, 241, 242
SEARCH (statins)..... 322
SENIORS (Nebivolol)..... 118
SERVE-HF (servo-ventilation in HF)..... 123
SHARP (Statin and Ezetimibe in CRF)..... 318
SHIFT (Ivabradine)..... 120
SHOCK (cardiogenic shock) 98, 99
SIGNIFY (Ivabradine) 77
SII-HF (PDE-5 inhibitors in heart failure) 306
SOAP-II (Dopamine) 128
SOLVD (Enalapril)..... 118
SOS (CABG / PCI)..... 79
SPAF 1, 2 and 3 (Warfarin)..... 216
SPARCL (statins and stroke).....294, 322
SPINAF (Warfarin) 216
SPRINT (HTN target)..... 326
STAR-AF (persistent AF)...214
STICH (revascularization)...123
STREAM (thrombolysis) 92, 93
SURVIVE (Levosimendan) 128
SWORD (post-myocardial infarction PVCs) 102, 231

Preface

This book is a very comprehensive review of all major topics in cardiology with an intention to help those preparing for initial and recertification exams in cardiology and those who want to review cardiology in an easy-to-do fashion. It is a compilation of over 1300 questions encompassing all the topics in cardiology. This has been edited by an internationally acclaimed teaching physician with an expertise in all aspects of cardiology. The book is organized in a question-and-answer format and is divided into easy-to-follow chapters related to different areas of cardiovascular medicine. The answers are explained in detail and are accompanied by references to major trials in cardiology and guidelines, and some clinical pearls where applicable. The explanations are clear and evidence based. The book highlights a special section on electrocardiograms which are of high resolution. The answers to the questions are given in depth, which will allow the examinees to prepare for this section and take the exam with greater confidence as this section is scored separately from the main exam. The chapters on imaging have questions relating to chest X-ray, cardiac computed tomography, echo, stress echo, cardiac magnetic resonance imaging, nuclear stress testing, and so on. The book also deals with questions relating to topics not usually encountered in similar books: for example, racial disparities in medicine, cardiac emergencies, and so on. The book also facilitates critical review of cardiovascular medicine to enhance one's diagnostic and therapeutic skills.

History and Physical Examination

1

1.1. A 25-year-old woman has a 2/6 ejection systolic murmur best heard in the second left intercostal space with normal S1. The S2 is split during inspiration, and P2 intensity is normal. No apical or parasternal heave. The murmur diminishes during expiration and standing up. What is the murmur likely due to?

A. Physiological or normal
B. Atrial septal defect (ASD)
C. Bicuspid aortic valve
D. Hypertrophic obstructive cardiomyopathy (HOCM)

1.2. A 29-year-old pregnant woman was found to a have a systolic murmur best heard in the second left intercostal space. It is rough and there was a palpable thrill in the same area and in the suprasternal notch. Patient is asymptomatic and has normal exercise tolerance. What is the likely explanation of the murmur?

A. Pulmonary stenosis (PS)
B. Normal flow murmur due to increased cardiac output
C. Posterior mitral leaflet prolapse causing an interiorly directed jet
D. Mammary soufflé

1.3. A 22-year-old patient has a hypoplastic radial side of the forearm and fingerized thumb. What this may be associated with?

A. ASD
B. Tetralogy of Fallot
C. Coarctation of aorta
D. Ebstein's anomaly

1.4. A 28-year-old man presented with a history of shortness of breath on exertion. On examination, the pulse rate was 76 bpm and blood pressure (BP) 126/80 mmHg. The left ventricular apex was prominent and forceful. The S1 and S2 were normal, but there was a 2/6 ejection systolic murmur best heard in the third right intercostal space. There was no appreciable variation with respiration, but there was an increase in intensity with the Valsalva maneuver and standing up. It seemed to be less prominent on squatting. There was no audible click. What is the murmur likely due to?

A. Valvular aortic stenosis
B. HOCM
C. Mitral valve prolapse (MVP)
D. Innocent murmur

1.5. A 36-year-old asymptomatic woman was found to have a systolic murmur best heard in the apex, but also in the aortic area. It was mid to late systolic and was associated with a sharp systolic sound. What is the likely cause of the murmur?

A. Posterior mitral leaflet prolapse
B. Anterior mitral leaflet prolapse
C. Valvular aortic stenosis
D. Aortic subvalvular membrane

1.6. A 78-year-old man with hypertension and diabetes mellitus presented with exertional shortness of breath of 6 months' duration. Examination revealed a 4/6 crescendo–decrescendo murmur best heard in the second right intercostal space.

Cardiology Board Review, First Edition. Ramdas G. Pai, Padmini Varadarajan and Sudha M. Pai.
© 2018 John Wiley & Sons, Ltd. Published 2018 by John Wiley & Sons, Ltd.

The first component of the second sound was soft. The murmur was also heard along the right carotid artery. What is this patient likely to have?

A. Mild aortic stenosis
B. Moderate or severe aortic stenosis
C. Pulmonary stenosis
D. MR

1.7. A thrill and a continuous machinery murmur in the left infraclavicular area is indicative of what?

A. Patent ductus arteriosus (PDA)
B. Increased flow due to left arm arteriovenous (AV) fistula for dialysis
C. Venous hum
D. Pulmonary AV fistula

1.8. Which of the following is not a feature of aortic coarctation?

A. A continuous murmur on the back
B. Lower blood pressure in legs compared with arm
C. Radiofemoral delay
D. Pistol shot sounds on femoral arteries

1.9. A 22-year-old newly immigrant woman was referred to high-risk pregnancy clinic because of clubbing and cyanosis. Examination in addition revealed a parasternal heave, 4/6 ejection systolic murmur in the third left intercostal space, normal jugular venous pressure (JVP), and oxygen saturation of 75%. What will you recommend after confirmation of the diagnosis?

A. Continue pregnancy with sodium restriction
B. Continue pregnancy, but deliver at 28 weeks
C. Advise termination of pregnancy
D. Perform percutaneous ASD closure and continue pregnancy

1.10. What is the murmur of ASD?

A. Continuous due to flow across the defect
B. Ejection systolic due to increased flow across the pulmonary valve
C. Mid-diastolic due to increased flow across the tricuspid valve
D. Continuous over lung fields due to increased flow in lungs

1.11. What is a systolic click that disappears on inspiration likely due to?

A. Pulmonary valvular stenosis
B. Bicuspid aortic valve
C. MVP
D. Pulmonary hypertension

1.12. A 36-year-old woman presented with an 8-month history of progressive exertional dyspnea. Physical examination revealed heart rate of 74 bpm, regular, BP 126/78 mmHg, no pedal edema. JVP and carotid upstroke were normal. Cardiac auscultation revealed normal S1, an accentuated P2 with narrow splitting of S2, an ejection click, and a 2/6 ejection systolic murmur. What is the likely diagnosis?

A. Pulmonary hypertension
B. PS
C. Aortic stenosis
D. ASD

1.13. Causes of prominent "a" wave in jugular venous pulsations include all of the following except which option?

A. PS
B. Pulmonary hypertension
C. Tricuspid stenosis
D. Aortic stenosis
E. ASD

1.14. What is a 6-year-old Amish boy in Pennsylvania with short stature, polydactyly, short limbs, absent upper incisor teeth with dysplasia of other teeth, and a systolic murmur most likely to have?

A. ASD
B. Ventricular septal defect
C. Aortic coarctation
D. PS

1.15. Which of the following describes ventricular septal defect murmur?

A. Holosystolic
B. Ejection systolic
C. Systolico-diastolic
D. None of the above

1.16. Clubbing and cyanosis in lower limbs, but not upper limbs, is indicative of which of the following?

A. PDA with coarctation of aorta
B. PDA with pulmonary hypertension
C. Ventricular septal defect Eisenmenger's
D. ASD Eisenmenger's with coarctation of aorta

1.17. A 46-year-old man presented with progressive fatigue and leg swelling. He had no significant past medical history except a front-on collision in a car he was driving. Examination revealed 2+ edema, raised JVP, and an enlarged liver, which seemed to expand during systole. What is the likely diagnosis?

A. Severe tricuspid stenosis
B. Severe tricuspid regurgitation (TR)
C. Constrictive pericarditis
D. Restrictive cardiomyopathy

1.18. A 23-year-old has a mid-diastolic rumble and sharp early diastolic sound. What is the likely explanation?

A. Mitral stenosis
B. Constriction
C. Restriction
D. Bicuspid aortic valve

1.19. A 28-year-old man has history of progressive fatigue and exertional shortness of breath over the last 6 months. Examination revealed raised JVP that seemed to increase with inspiration and a sharp precordial sound in early diastole. What is the most likely diagnosis?

A. Right ventricular infarct
B. Tricuspid stenosis
C. Constrictive pericarditis
D. Restrictive cardiomyopathy

1.20. A 66-year-old woman with left breast cancer post mastectomy, radiation, and chemotherapy was admitted with shortness of breath, heart rate of 120 bpm, and BP of 90/60 mmHg. On slow cuff deflation during BP measurement, Korotkoff's sounds started at 90 mmHg during expiration only and throughout the respiratory cycle at a cuff pressure of 70 mmHg. An echocardiogram was obtained. What is this likely to show?

A. Akinesis of left anterior descending area
B. Thick pericardium
C. Large pericardial effusion
D. Large, globally hypokinetic left ventricle.

1.21. Features of restrictive cardiomyopathy may include all of the following except which option?

A. Raised JVP
B. Loud S3
C. Kussmaul's sign
D. A diastolic knock in pulmonary area

1.22. Pulsus paradoxus despite tamponade may not be present in which of the following?

A. ASD
B. Aortic stenosis
C. Mitral stenosis
D. Old age

1.23. Pulsus paradoxus may occur in all of the following except which option?

A. Tamponade
B. Status asthmaticus
C. Pulmonary embolism
D. Aortic stenosis

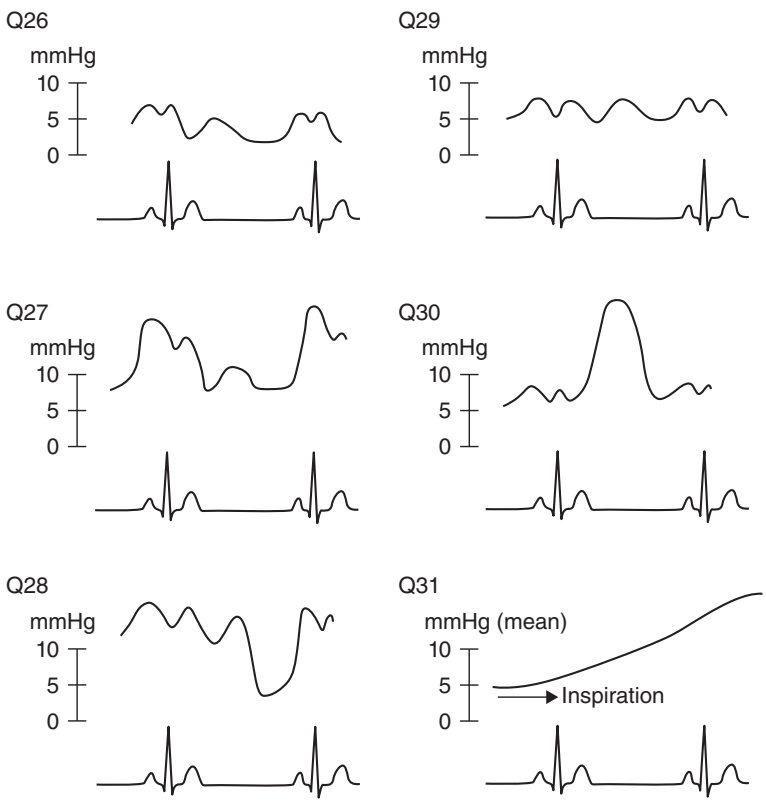
1.24. Square sign during Valsalva maneuver occurs in which of the following?

A. HOCM
B. MVP
C. Aortic stenosis
D. Congestive heart failure

1.25. An abnormal Schamroth's test may be found in all of the following except which option?

A. Tetralogy of Fallot
B. Subacute bacterial endocarditis
C. Left atrial myxoma
D. Aortic stenosis

1.26–1.31. For the jugular vein or RA pressure tracings shown in Figures 1.26–1.31, match with an appropriate clinical scenario from the following choices:

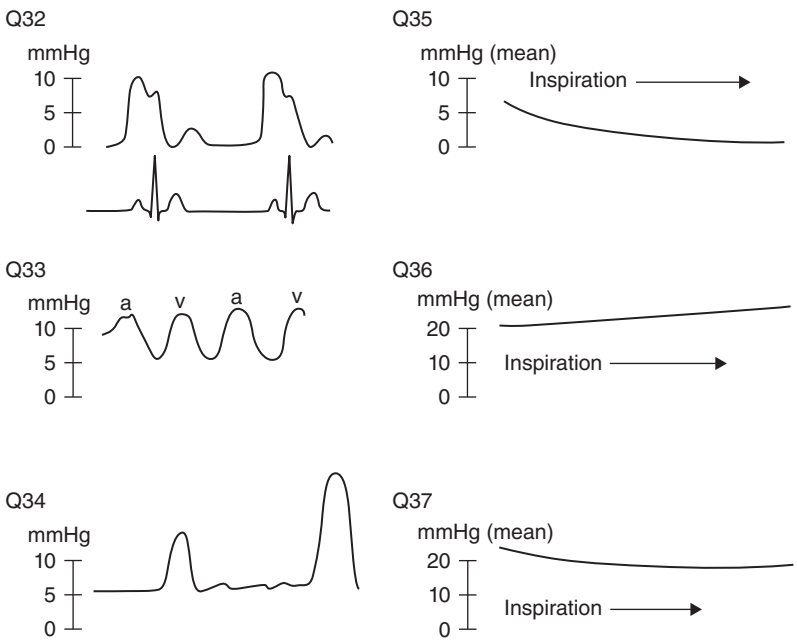


Figures 1.26–1.31

A. Normal
B. Pericardial constriction
C. Restrictive cardiomyopathy
D. ASD
E. Tricuspid stenosis
F. TR
G. Cardiac tamponade
H. Superior vena cava syndrome
I. Heart failure
J. PS

1.32–1.37. For the jugular vein or RA pressure tracings shown in Figures 1.32–1.37, match with an appropriate clinical scenario from the following choices:

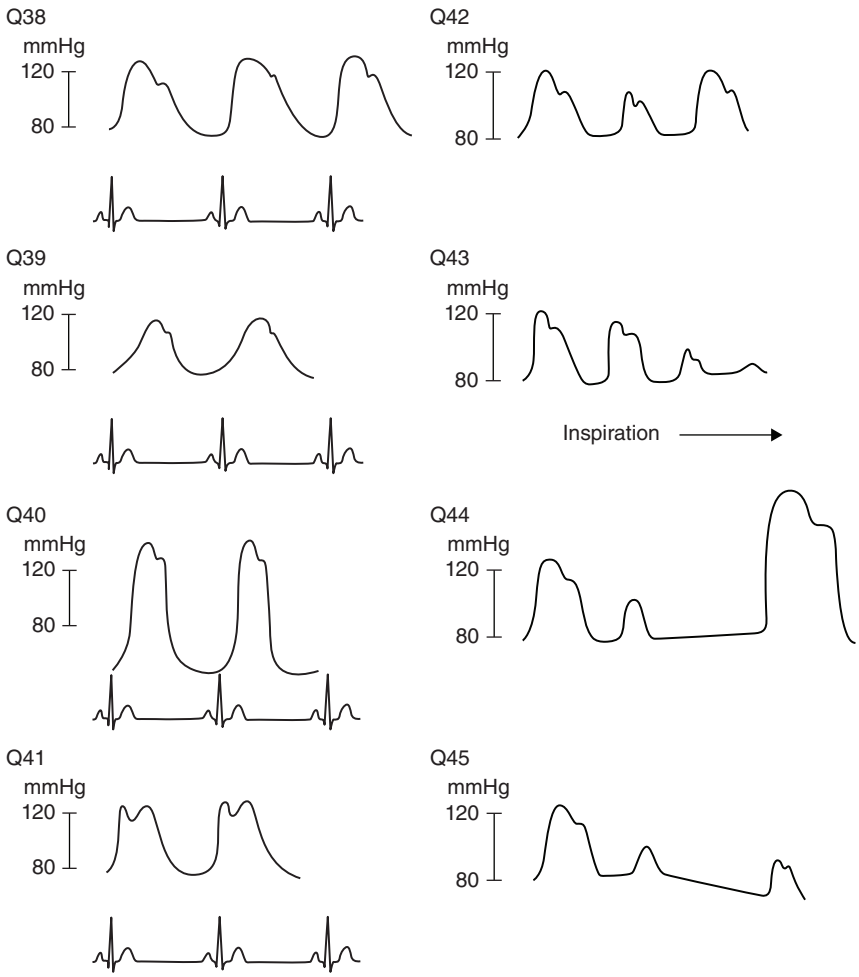
A. Normal
B. Pericardial constriction
C. Restrictive cardiomyopathy
D. ASD
E. Tricuspid stenosis
F. TR
G. Cardiac tamponade
H. Superior vena cava syndrome
I. Heart failure
J. PS
K. Complete heart block



Figures 1.32–1.37

1.38–1.45. For the carotid pulse or arterial pressure tracings shown in Figures 1.38–1.45, match with an appropriate clinical scenario from the following choices:

A. Normal
B. Constriction
C. Aortic stenosis
D. AR
E. Mitral stenosis
F. Mixed aortic stenosis and AR
G. Cardiac tamponade
H. HOCM
I. Heart failure
J. Complete heart block
K. MR
L. Premature ventricular contraction (PVC)



Figures 1.38–1.45

Answers

1.1. A. Physiological or normal.

The murmur is <3/6 in intensity and diminishes with standing, when venous return is less, indicating a flow murmur. S2 split during inspiration only is physiological. During inspiration, increased venous return and pulmonary flow prolongs right ventricular (RV) ejection. This delays P2.

1.2. A. Pulmonary stenosis (PS).

A murmur associated with a thrill indicates that it is pathological and not just due to increased cardiac output. A thrill in the suprasternal notch is pathognomonic of PS. Valvular PS would be associated with an ejection click which diminishes with inspiration. Left parasternal heave would be indicative of RV hypertrophy (RVH).

1.3. A. ASD.

The features are suggestive of Holt–Oram syndrome.

1.4. B. HOCM.

In HOCM, the left ventricular (LV) outflow obstruction is dynamic and is increased by an increase in LV contractility or a reduction in LV size. Standing, Valsalva maneuver, and amyl nitrite reduce venous return, reduce LV filling, and increase systolic anterior motion of the anterior mitral leaflet (SAM), resulting in increased LV outflow tract (LVOT) obstruction. Squatting kinks leg arteries, raising peripheral resistance and hence an increase in LV volume. This reduces SAM and LV outflow obstruction. Valvular aortic stenosis murmur intensity is flow dependent, and hence reduction in venous return with standing or Valsalva maneuver as well as increase in peripheral resistance with squatting would diminish the murmur. In mitral valve prolapse (MVP), an increase in LV volume would reduce prolapse, and a reduction in LV volume would lengthen the murmur by producing earlier prolapse. MVP is generally associated with a mid-systolic click.

1.5. A. Posterior mitral leaflet prolapse.

The systolic click and late systolic murmur indicate MVP. In anterior leaflet prolapse, the mitral regurgitation (MR) jet is directed posteriorly and murmur may be conducted to the axilla. In posterior leaflet prolapse, the jet is anterior wall hugging, along the aortic root, which facilitates its conduction to the aortic area.

1.6. B. Moderate or severe aortic stenosis.

This is a classic aortic stenosis murmur with carotid conduction. Soft A2 (first component of S2 indicates significant aortic stenosis). Features of severe aortic stenosis are late-peaking murmur, absent A2, paradoxic splitting of S2 (i.e. split during expiration instead of inspiration), and slow-rising carotid pulse (pulsus parvus et tardus).

1.7. A. Patent ductus arteriosus (PDA).

Though the other conditions can produce continuous murmurs, they are not associated with a thrill or machinery character.

1.8. D. Pistol shot sounds on femoral arteries.

Pistol shot sounds occur in severe aortic regurgitation (AR). Others are features of aortic coarctation.

1.9. C. Advise termination of pregnancy.

The findings are typical of tetralogy of Fallot, and the murmur is due to PS. Murmur of ASD is due to flow and softer and not associated with clubbing or cyanosis unless associated with Eisenmenger's syndrome. Tetralogy of Fallot is associated with extremely high risk, and pregnancy should be terminated.

1.10. B. Ejection systolic due to increased flow across the pulmonary valve.

Flow across the defect and the lungs does not produce murmurs. It takes a torrential shunt to produce a mid-diastolic flow murmur across the tricuspid valve.

1.11. A. Pulmonary valvular stenosis.

In severe PS, due to low pulmonary artery (PA) pressure, an increase in venous return to right ventricle during inspiration may open the pulmonary valve before systole, eliminating the ejection click.

1.12. A. Pulmonary hypertension.

This is suggested by loud P2. In pulmonary hypertension, P2 moves closer to A2 due to higher pulmonary valve closure pressure, and S2 may be single when PA pressure approaches systemic pressure. Ejection click and soft ejection systolic murmur may occur because of PA dilation. Other features of pulmonary hypertension may include a palpable PA in second left intercostal space, a palpable P2 or diastolic knock, parasternal heave due to RVH and prominent "a" wave in jugular venous pulsation due to RVH resulting in accentuated right atrial (RA) systole. PS results in a louder murmur and diminished P2. ASD results in wide, fixed, splitting of S2.

1.13. E. ASD.

Prominent "a" wave occurs due to forceful RA systole, and this can occur against stenotic tricuspid valve, hypertrophied RV (PS and pulmonary hypertension) or hypertrophied ventricular septum (aortic stenosis, hypertrophic cardiomyopathy, or hypertension). In ASD, defect in the atrial septum would not allow a prominent "a" wave, even in the presence of pulmonary hypertension, as the right atrium would decompress into the left atrium during atrial systole.

1.14. A. ASD.

ASD or common atrium as part of Ellis–van Creveld syndrome or mesoectodermal or chondroectodermal dysplasia is an autosomal recessive inheritance disorder that occurs in old-order Amish population. The *EVC* gene is on chromosome number 4, short arm. It is a form of ciliopathy. Other ciliopathies that result in abnormal organogenesis include Bardet–Biedl syndrome, polycystic kidney and liver disease, Alstrom syndrome, Meckel–Gruber syndrome, and some forms of retinal degeneration, and so on.

1.15. A. Holosystolic.

1.16. B. PDA with pulmonary hypertension.

In PDA Eisenmenger's, the shunt reversal through PDA causes desaturation in lower part of the body only, resulting in central cyanosis and clubbing in lower extremities and not upper extremities.

1.17. B. Severe tricuspid regurgitation (TR).

Liver that is pulsatile (expansile) in systole is indicative of a powerful RA "V" wave, and this suggests severe TR. This can also be seen in the jugular venous pulsation. Sternal compression during the motor vehicle accident likely caused a flail tricuspid valve and severe TR. Liver pulsation in tricuspid stenosis is pre-systolic. Liver pulsations are not seen in constriction or restriction.

1.18. A. Mitral stenosis.

This is typical mitral stenosis with pliable leaflets, which causes opening snap. A2-OS interval is a good measure of mitral stenosis severity. Normally, 70–100 ms (same as isovolumetric relaxation time). Less than 70 ms indicates high left atrial pressure, suggesting severe mitral stenosis.

1.19. C. Constrictive pericarditis.

Rise in JVP is paradoxical (Kussmaul's sign), and sharp protodiastolic sound is pericardial knock – classic features of constriction. Kussmaul's sign occurs because of lack of transmission of negative intrathoracic pressure to the right atrium

through the rigid pericardium. Hence, increased venous return during inspiration causes a rise in RA pressure. In tricuspid stenosis, inspiratory increase in venous return may not readily empty into right ventricle, causing a paradoxical rise in JVP with inspiration. Kussmaul's sign can occur in RV infarct but occurs in the setting of inferior myocardial infarction. Restrictive cardiomyopathy may be associated with S3, which is less sharp (a thud), but no venous paradox.

1.20. C. Large pericardial effusion.

This is typical cardiac tamponade with classic paradoxic pulse, hypotension, and tachycardia. Constriction causes venous paradox.

1.21. C. Kussmaul's sign.

As pericardium is normal, inspiratory negative intrathoracic pressure is transmitted to cardiac chambers, and hence the venous paradox does not occur. Diastolic knock is palpable loud P2, a feature of pulmonary hypertension that is common in restrictive LV physiology.

1.22. A. ASD.

Pulsus paradoxus may not be present when LV filling is not affected by phase of inspiration due to lack of interventricular dependence, as in ASD, or LV filling from other sources, such as severe AR or MR.

1.23. D. Aortic stenosis.

1.24. D. Congestive heart failure.

See explanation in Box 1.1 Clinical Pearls. This is because though a Valsalva maneuver reduces left-sided venous return, it does not affect LV stroke volume as it is already well filled and beyond the peak of Starling's curve. Increase in intrathoracic pressure is transmitted to the aorta, causing an increase in aortic pressure.

1.25. D. Aortic stenosis.

This test is named after South African cardiologist for diagnosis of clubbing. In clubbing, the angle between the nail and nail fold is >165° and when nails of fingers from two sides are apposed, the gap between them disappears. Clubbing is seen in cardiac conditions (in addition to a variety of pulmonary diseases) in subacute bacterial endocarditis, congenital cyanotic heart diseases, and left atrial myxoma.

1.26. A. Normal.

Note the mean RA pressure of <5 mmHg and the "a" wave due to atrial systole is slightly higher than the "V" wave, which occurs because of RA filling on the closed tricuspid valve. A smaller "V" wave indicates a compliant right atrium. The sharp "C" wave that coincides with the QRS complex of the electrocardiogram is due to a combination of tricuspid valve closure and transmitted carotid impulse.

1.27. E. Tricuspid stenosis.

Note the large "a" wave as the RA contracts against a stenosed tricuspid valve; the gradient is reflected as large "a" wave. Note that the mean RA pressure is slightly elevated as well commensurate with transtricuspid gradient. In conditions causing RVH (pulmonary hypertension, PS, aortic stenosis with septal hypertrophy), the "a" wave may be prominent due to noncompliant RV (RV fourth heart sound), but mean RA pressure may not be high unless there is heart failure.

1.28. B. Pericardial constriction.
Note elevated RA pressure with rapid "Y" descent.

1.29. D. ASD.
In ASD, the "a" and "V" waves would be of similar height because the defect leads to equilibration of the LA and RA pressures.

1.30. F. TR.
Large "V" wave is due to TR filling up RA during systole. When the "V" wave pressure is about 25–30 mmHg, it may become palpable to the examining finger and associated with expansile liver.

1.31. B. Pericardial constriction.
The increasing mean RA pressure with inspiration is the venous paradox or Kussmaul's sign. This is because of dissociation between intrathoracic and intrapericardial pressures because of thick pericardium. During inspiration, the intrathoracic pressure drops, increasing venous return to the right atrium, but the intrapericardial and intra-RA pressure does not drop and returning blood increases the pressure further. Kussmaul's sign can occur even in acute pericarditis and RV infarcts, the latter invoking pericardial restraint.

1.32. J. PS.
Note a large "a" wave with near-normal mean RA pressure. Contrast this with tricuspid stenosis.

1.33. G. Cardiac tamponade.
Note the raised RA pressure with prominent "X" and "Y" troughs.

1.34. K. Complete heart block.
The intermittent large waves are "cannon a" waves when atria and ventricles happen to contract simultaneously due to AV dissociation.

1.35. A. Normal.
The RA pressure is <5 mmHg and drops with inspiration.

1.36. H. Superior vena cava syndrome.
Note the high JVP which does not drop on inspiration as superior vena cava is blocked and jugular vein is not in communication with right atrial hemodynamics or pulsatile changes. In contrast to constriction, the JVP in superior vena cava syndrome is nonpulsatile. It would be high in both.

1.37. I. Heart failure.
High JVP that drops with inspiration.

1.38. A. Normal.
This is the typical normal tracing. Note the fairly rapid upstroke, pulse pressure of about 40 mmHg, dicrotic notch and dicrotic wave.

1.39. C. Aortic stenosis.
Note the very slow rise, attributable to high blood flow velocity across the valve which converts pressure to kinetic energy.

1.40. D. AR.
Note rapid upstroke, rapid downstroke (water-hammer pulse), wide pulse pressure, and low diastolic pressure due to peripheral vasodilation. This can also occur in PDA and large AV fistulae.

1.41. F. Mixed aortic stenosis and AR.

This is called pulsus bisferiens or double pulse. Can also occur in HOCM.

1.42. I. Heart failure.

This is pulsus alternans. Alternating strong and weak pulse with regular RR interval due to alternating stronger and weaker myocardial contraction with every other beat attributable to altered calcium handling by contractile proteins. It is a sign of severe systolic dysfunction.

1.43. G. Cardiac tamponade.

BP drop with inspiration is called pulsus paradoxus. An inspiratory drop of >10 mmHg may indicate tamponade.

1.44. L. Premature ventricular contraction (PVC).

With appropriate increase in pulse pressure in the post PVC beat due to a combination of increased preload due to long filling period and increased contractility due to force–frequency relationship.

1.45. H. HOCM.

In this patient, after PVC, instead of an augmented pulse there is a smaller pulse volume. This is due to the fact that increased contractility in the post PVC beat increases dynamic LVOT obstruction and reduces stroke volume. This is called Brockenbrough phenomenon on cardiac catheterization. This contrasts with valvular aortic stenosis, where pulse pressure increases after a PVC.

Box 1.1 Clinical Pearls

- Loud S1 occurs when mitral valve closes forcefully from open position against transmitral gradient or prematurely and occurs in mitral stenosis, short pulmonary regurgitation (PR) interval, and hyperdynamic circulation.
- S1 is soft in MR, long PR interval, and severe AR. In severe AR, mitral valve may move toward closure in presystole.
- P2 can be loud in pulmonary hypertension (higher pulmonary valve closure sound) and dilated PA (better P2 transmission).
- S2 may be paradoxically split when aortic valve closure is delayed and comes after P2 as in left bundle branch block, severe aortic stenosis, severe LV dysfunction, PDA (increased transaortic flow). S2 is split in expiration and not in inspiration when RV filling and ejection time are increased.
- Only right-sided sound/murmur that is attenuated by inspiration is pulmonary ejection click of valvular PS as inspiratory increase in venous return to right ventricle in the presence of RVH may cause an increase on RV end diastolic pressure high enough to open the pulmonary valve as PA pressure is lower.
- Carey Coombs murmur is mid-diastolic mitral murmur due to mitral valvulitis in rheumatic fever.
- Austin Flint murmur is mitral mid-diastolic murmur heard in severe AR. Potential explanations include: AR jet causing anterior mitral leaflet vibration, or mitral/AR jet interaction or AR jet causing partial diastolic closure of anterior mitral leaflet.
- Graham Steel murmur is early diastolic murmur of PR that occurs in severe pulmonary hypertension. Higher PA diastolic pressure causes turbulence of PR jet and the murmur.

- Mid-diastolic murmur of mitral stenosis is best heard with the bell without much pressure as it is a low-frequency murmur and better heard in left lateral position. Presystolic accentuation indicates atrial contraction.
- Tapping apex typically occurs in mitral stenosis and it is palpable S1.
- Maneuvers are helpful in evaluating murmurs. Inspiration increases right-sided venous return and augments right-sided murmurs. Standing reduces venous return and after three or four beats LV filling as well reduces its size. This may augment HOCM murmur and lengthen MR murmur of MVP. Squatting kinks limb arteries and increases afterload. This may reduce murmurs of valvular aortic stenosis through reduced stroke volume and HOCM murmur through an increase in LV volume and shorten murmur of MVP through increasing LV volume and reducing prolapse.
- The Valsalva maneuver involves expiration against a closed glottis, increasing the intrathoracic pressure. There are four phases of heart rate and BP response. Normal response includes the following:
  - Phase 1. Early during the Valsalva maneuver, pressure on the intrathoracic aorta and pulmonary veins emptying into left heart transiently increases filling, stroke volume, and BP with reflex slowing of heart.
  - Phase 2. With a continued Valsalva maneuver, LV filling diminishes and lowers stroke volume and BP, resulting in compensatory tachycardia. Reflex peripheral vasoconstriction slowly increases BP and lowers heart rate.
  - Phase 3. With release of the Valsalva maneuver, pressure on the aorta drops, and BP drops with some increase in heart rate.
  - Phase 4. Left ventricle fills, with increase in stroke volume with continued peripheral vasoconstriction causing BP to overshoot the baseline value. This will reflexly reduce heart rate below baseline.

  Phase 2 is used in dynamic auscultation.
- In HOCM, the Valsalva maneuver results in smaller left ventricle size causing increased LVOT obstruction and an increase in murmur intensity.
- In MVP, reduced LV volume with phase 2 Valsalva results in earlier and greater prolapse and the MR murmur lengthens.
- Heaving apex denotes LV hypertrophy, forceful apical lift signifies LV volume overload, tapping apex loud S1, and bifid apex with presystolic lift LV occurs due to a combination of LVH with a forceful atrial kick causing S4 as it occurs in hypertrophic cardiomyopathy.
- Left parasternal or precordial bulge indicates RVH occurring before the rib cage ossified (young age), and parasternal lift or heave indicates RVH starting after childhood.
- A downward tug on larynx held up with fingers after deglutition indicates aortic arch aneurysm. Also called tracheal tug or Oliver's sign, occurs with every heartbeat.
- A large, sharp systolic wave in jugular venous pulsation during systole is the cannon wave. This occurs when the right atrium contracts over closed tricuspid valve, as in complete heart block (intermittent) or junctional or idioventricular rhythm with retrograde ventriculoatrial conduction.

Electrocardiography 2

ECG diagnostic criteria are listed in Box 2.1.

For the tracings in the questions/figures in this section, please analyze carefully and list the important findings and possible clinical setting. Answers are found at the end of the chapter.

Answers

2.1. Second-degree atrioventricular (AV) block, Mobitz type I (AV Wenckebach). Note increasing PR interval and PR interval being the shortest after a dropped beat. Also, note that the patient has intraventricular conduction delay (IVCD) and lateral T wave inversion. Despite IVCD, it is less likely to be trifascicular block as AV Wenckebach is generally a nodal rather than infra-Hisian phenomenon.

2.2. Right ventricular (RV) hypertrophy (RVH) with strain and biatrial enlargement. R in V1 >5 mm with right axis deviation and ST–T changes in right chest leads support RVH. P wave amplitude >3 mm supports right atrial enlargement and P-terminale in V1 > 1 × 1 box supports left atrial enlargement.

2.3. Sinus rhythm with bifascicular block. Note right bundle branch block (RBBB) and left axis deviation with mean QRS axis less than −30° suggesting left anterior fascicular block (LAHB). Also note that the peak of R wave is earliest in III, followed by II, and then I, indicating late activation of left ventricular (LV) lateral wall supplied by anterior fascicle. Inferior wall is supplied by posterior fascicle and R wave peaks early in these leads.

2.4. Sinus arrhythmia with short PR interval suggesting Lown–Ganong–Levine syndrome. Note that there is no delta wave or QRS prolongation indicating Wolff–Parkinson–White (WPW) syndrome. In Lown–Ganong–Levine syndrome, the accessory pathway is atrio-Hisian, shortening the PR interval. In WPW syndrome, AV preexcitation of a portion of ventricular myocardium results in delta wave and QRS prolongation.

2.5. Atrial fibrillation. Note absence of P wave and irregularly irregular ventricular response. Also note low QRS voltage (<5 mm in limb and <10 mm in chest leads), which should raise the suspicion of chronic obstructive pulmonary disease, pericardial effusion, or diffuse myocardial disease.

2.6. Acute anterior ST elevation myocardial infarction (STEMI). Note hyperacute, tombstone ST elevation in V2 and V3.

2.7. Hyperkalemia. Note peaked, tall T waves in V2 and V3.

2.8. Junctional tachycardia. P waves are inverted in inferior leads with superior axis indicating junctional or low atrial origin.

2.9. RVH. qR in V1 with right axis deviation and strain pattern in right chest leads is suggestive of RVH.

2.10. WPW syndrome (? posteroseptal).

2.11. Seven beats of accelerated idioventricular rhythm, followed by a fusion beat and then accelerated junctional rhythm. This is suggestive of digoxin toxicity.

2.12. Atrial flutter with 2 : 1 conduction. Flutter waves are clearly visible in inferior leads.

2.13. Posterior myocardial infarction. Note tall R waves in V1 and V2 with upright T wave associated with Q waves inferolaterally. In RVH, one would expect to see strain pattern in right chest leads.

2.14. Ventricular tachycardia. Broad complexed tachycardia with RBBB morphology with left rabbit ear, QRS duration of 200 ms and indeterminate axis – all suggestive of ventricular tachycardia (VT) rather that supraventricular tachycardia (SVT) with aberrancy.

2.15. Atypical atrial flutter with 3 : 1 conduction, intermittent RV pacing (third and last three beats) and one fusion complex (fifth beat).

2.16. Acute anterior STEMI. Note Q waves and ST elevation of 3–4 mm in V1 and V2.

2.17. Sinus rhythm with low QRS voltage (<5 mm in limb leads or <10 mm in chest leads). Consider pericardial effusion, emphysema.

2.18. Nonconducted P (second from right) followed by a P associated with a ventricular escape beat showing T wave inversion. Consistent with Mobitz type II AV block. Also note anterior Q wave, RBBB and LAFB – a substrate for trifascicular block.

2.19. Atrial fibrillation with rapid ventricular response. Also note low QRS voltage and diffuse ST elevation, suggesting pericarditis with effusion which may result in atrial fibrillation through atrial irritation.

2.20. Acute pericarditis. Note diffuse concave-up ST elevation and PR segment depression in most of the leads and reciprocal PR segment elevation and ST depression in aVR.

2.21. Episodes of complete heart block. Note >1 nonconducted P in a row. Note old inferior and acute anterior STEMI and mechanism of heart block is likely to be infra-Hisian with high risk of lack of escape rhythm.

2.22. Premature ventricular contractions (PVCs), three-beat VT (beats 2–4), accelerated idiojunctional rhythm (fairly regular narrow complex with no preceding P at a rate of 65 bpm, beats 9–12), Afib (lack of a P wave), short QT interval. These are highly indicative of digoxin toxicity. Digoxin toxicity blocks AV node and promotes subsidiary pacemakers at a faster rate.

2.23. Junctional rhythm with ventricular bigeminy.

2.24. Junctional rhythm with RBBB (beats 1, 4, and 5) with intermittent V-pacing (beats 2, 3, 6, and 7). Note a small pacer spike, changed QRS morphology upright in I, and different T wave morphology with paced beats.

2.25. Dual-chamber pacing.

2.26. Ventricular bigeminy.

2.27. Atrial pacing, ventricular tracking with ventricular pseudofusion. The V-spike before QRS is coincidental and QRS has normal conducted morphology. Lengthening AV delay will conserve the battery.

2.28. Dual-chamber pacing with ventricular couplet (beats 7 and 8).

2.29. Atrial flutter with 2 : 1 conduction and intermittent V-pacing.

2.30. WPW syndrome.

2.31. Dual-chamber pacer with atrial sensing and V-pacing producing slightly fused complex. Only very initial part of QRS is slightly slurred, indicating pacer-induced depolarization and rest of the QRS is normally conducted. Note LAFB as well.

2.32. High-grade AV block. The P waves are numbered. The atrial rate is about 86 bpm, and between 1 and 2 (rate 43) a P wave is dropped, indicating 2 : 1 sino-atrial block (produced by a nonconducted premature atrial contraction (PAC) between 1 and 2 through concealed retrograde conduction. The PAC is deforming the ST segment). Then there is 2 : 1 A : V block till 7 followed by two successive Ps being dropped (complete AV block) with a ventricular escape beat at 9 burying a P wave.

2.33. Narrow complex regular tachycardia at a rate of 150 .bpm without a discernible P wave. Likely paroxysmal SVT and possible atrioventricular nodal reentry tachycardia.

2.34. Broad complex tachycardia at a rate of 140 bpm, suggestive of VT. Note negative concordance in chest leads, superior axis, QRS duration of >200 ms, and slow upstroke of QRS complex – all suggestive of VT.

2.35. Atrial flutter with 2 : 1 conduction. Note clear flutter waves in lead II. There is a single PVC.

2.36. Atrial paced rhythm with normal AV conduction and normal QRS.

2.37. Atrial sensed and ventricular paced rhythm. Note that QRS is upright in V1, suggesting probable LV rather than RV pacing. Patient has a biventricular (BiV) pacer.

2.38. WPW syndrome. Note the delta waves in V4 and V5.

2.39. Dual-chamber pacer with atrial tracking and V-pacing producing fusion QRS complexes with initial portion due to pacing and remainder being conducted.

2.40. VOO pacing with pacer competing with junctional rhythm producing fully paced beat (1), fusion complex (2), pseudofusion (3), and lack of sensing (5–9). Also note QT prolongation. T wave inversion can occur because of repolarization memory secondary to V-pacing.

2.41. Dual-chamber pacing.

2.42. WPW syndrome, probably posteroseptal pathway because of inferior Q waves, positive delta waves in anterolateral leads, and rapid transition from V1 to V2.

2.43. BiV pacer with atrial and LV pacing. Note that QRS is negative in lateral leads and positive in V1, indicating LV pacing.

2.44. Broad complex tachycardia at a rate of 140 bpm with QRS duration of 160 ms, RBBB pattern with right rabbit ear and right axis deviation and rapid upstroke of initial part of QRS (in V5/V6) with broadening of latter part suggesting SVT with aberrancy. Note that the PVC did not reset the rhythm.

2.45. Broad complex tachycardia with monophasic RBBB pattern in V1, right axis deviation, and QRS duration of 160 ms. No P waves seen. Note rapid rise of QRS voltage in V5 and V6. The patient had SVT with aberrancy.

2.46. Atrial fibrillation for the first five beats, then V-pacing for a beat followed by sinus rhythm with first-degree AV block and lack of V-sensing in last three beats. Also note acute anterior STEMI.

2.47. BiV pacer. Patient is paced in atrium and left ventricle, producing RBBB QRS morphology.

2.48. Blocked PACs. The pauses are due to nonconducted PACs which occurred on the T wave and during refractory period of AV node. This does not signify AV nodal disease. When there are pauses, always look for nonconducted PACs. Also note QT prolongation.

2.49. Acute inferolateral STEMI. Note reciprocal ST depression in aVR; in pericarditis, there is reciprocal ST and PR segment elevation in aVR.

2.50. BiV hypertrophy. R in V1 is >5 mm and R/S in V1 is 1, suggesting RVH. R in V5 plus S in V2 is 35 mm, and ST depression in V5 and V6 suggests LV hypertrophy (LVH).

2.51. Normal electrocardiogram.

2.52. Acute inferior STEMI with near-complete ST segment resolution and inferior Q waves.

2.53. Acute inferolateral STEMI.

2.54. Multifocal atrial tachycardia. Note three different P wave morphologies and average rate >100 bpm.

2.55. Sinus tachycardia.

2.56. Intermittent dropped QRSs without progressive PR prologation suggesting second-degree Mobitz type II AV block. Also note that patient has left bundle branch block (LBBB), further supporting that the mechanism of AV block is likely infra-Hisian rather than intranodal. High risk of complete heart block.

2.57. Bifascicular block. Patient has RBBB and right axis deviation, suggesting left posterior fascicular block. Note the peaks of R wave in leads II and III follow lead I, suggesting activation spreading from lateral to inferior wall, the region of posterior fascicle.

2.58. Dual-chamber pacing, but QRS is native rather than paced. The V-spike comes before QRS, but QRS is narrow and has near-normal morphology.

2.59. Inferior myocardial infarction, age undetermined, possibly recent (slight ST elevation in leads III and aVF.

2.60. Bifascicular block with RBBB and LAFB. Also note absence of r in leads V1 to V4, indicating anterior myocardial infarction. Hence, the likely mechanism is diffuse conduction system disease through ischemia and signifies high risk because of infra-Hisian mechanism and extent of myocardial involvement.

2.61. Severe hyperkalemia with near sine wave appearance: Note peaked T waves, QRS prolongation, and absent P waves.

2.62. Atrial flutter with 2 : 1 conduction. The atrial rate is 240 bpm and ventricular rate is 120 bpm.

2.63. Marked respiratory sinus arrhythmia. Note that the P wave morphology is constant and cyclical changes in P–P intervals are consistent with frequency of respiration. It is a marker of vagotonia and seems to be more marked in the young and at slow heart rates.

2.64. Atrial tachycardia with variable block.

2.65. Paroxysmal atrial fibrillation with rapid ventricular response.

2.66. Atypical atrial flutter with variable block and IVCD of LBBB morphology.

2.67. Atrial tachycardia with 3 : 1 conduction. Atrial rate is about 225 bpm, and this could also be slow flutter because of antiarrhythmic therapy.

Box 2.1 ECG Diagnostic Criteria

Normal sinus P wave

- P wave duration <120 ms
- Amplitude ≤2.5 mm
- P wave axis between 45° and 75° in frontal plane

Criteria for left atrial enlargement

- P wave duration >120 ms in lead II
- Notched P wave in lead II with inter-notch distance >40 ms (P-mitrale)

- P-terminale in V1 >0.04 mm
- P wave axis between +45° and −30° in frontal plane (left axis deviation)

Criteria for right atrial enlargement

- P wave amplitude >2.5 mm in lead II (P-pulmonale)
- Area under initial positive part of P wave in V1 >0.06 mm
- P wave axis >75° in frontal plane (right axis deviation)

Criteria for LVH

- Sokolov criteria: S in V1 plus R in V5 or V6 >35 mm; R in aVL >11 mm
- Cornell criteria: S in V3 plus S in V1 ≥28 mm for men and ≥20 mm for women
- Romhilt–Estes criteria (LVH if 5 points): R wave in any limb lead ≥20 mm, or S in V1 or V2 ≥30 mm, or R in V5 or V6 ≥30 mm (3 points); left atrial abnormality (3 points); ST–T changes without digoxin (3 points) or with digoxin (1 point); QRS axis <−30° (2 points); QRS duration >90 ms (1 point); intrinsicoid deflection in V5 or V6 >50 ms (1 point)

Criteria for RVH

- R in V1 ≥7 mm
- QR in V1
- R/S in V1 >1 with R at least 5 mm
- R/S in V5 or V6 <1
- $S_1Q_3T_3$ pattern (pulmonary embolism)
- $S_1S_2S_3$ pattern

Criteria for BiV hypertrophy

- Tall R in both left and right chest leads
- LVH with right axis deviation
- LVH with deep S in V5 or V6
- LVH with shift of precordial transition (R/S = 1) to the left of V4

Criteria for LAFB

- QRS axis <−45° with rS in inferior leads (i.e., no inferior Q waves) and qR in high lateral leads plus QRSd <120 ms

Criteria for left posterior fascicular block

- QRS axis >120° with RS in high lateral leads and qR in inferior leads plus QRSd <120 ms

Criteria for LBBB

- Broad notched R wave in lateral leads, absent q in left-sided leads (septal activation will be right to left), QRSd ≥120 ms

Criteria for RBBB

- Broad notched R wave in V1 and V2 with right rabbit ear, deep slurred S in left-sided leads (reciprocal of R′), QRSd ≥120 ms

Causes of tall R wave in V1

- RVH (generally with right axis deviation and secondary ST–T changes or right atrial enlargement)
- True posterior infarct (generally with upright T, inferior or lateral Q)
- Hypertrophic obstructive cardiomyopathy (due to septal depolarization)
- Duchenne muscular dystrophy
- RBBB
- WPW syndrome with posterior or lateral pathways
- Heart shifted to right

Causes of Q waves

- Normal in V1/V2 and III (in lead III will disappear with deep breath which makes heart vertical)
- Myocardial infarction
- Myocardial infiltration (sarcoid, amyloid)
- Myocarditis
- WPW syndrome
- LBBB results in Q in V1/V2
- Hypertrophic obstructive cardiomyopathy (septal hypertrophy causing Q in lateral leads)

Causes of ST elevation

- Normal variant (early repolarization, generally V1–V4)
- Myocardial injury (convex up)
- LV aneurysm (persistent beyond 6 months)
- Pericarditis (concave up, diffuse, ST and PR elevation in aVR, PR depression)
- Brugada syndrome
- Hyperkalemia ("dialyzable current of injury")
- Type IC antiarrhythmic agents
- LVH and LBBB (in right chest leads as reciprocal of ST depression on left chest leads)

Hyperkalemia

- Peaked T wave (early sign)
- Increased QRS duration
- Absent P wave
- Sine wave morphology in late stage

Hypercalcemia

- Shortened QT interval

Hypocalcemia

- QT lengthening (especially ST segment lengthening)

Chest X-Ray in Cardiology

3

3.1. A 52-year-old African American male was admitted with complaints of shortness of breath and edema. He has a history of methamphetamine use. A chest X-ray (Figure 3.1a) was performed in the emergency room (ER). What does the chest X-ray show?

A. Cardiomegaly
B. Cardiomegaly, automatic implantable cardioverter-defibrillator (AICD) lead
C. Normal findings
D. Cardiomegaly, AICD lead, left pleural effusion

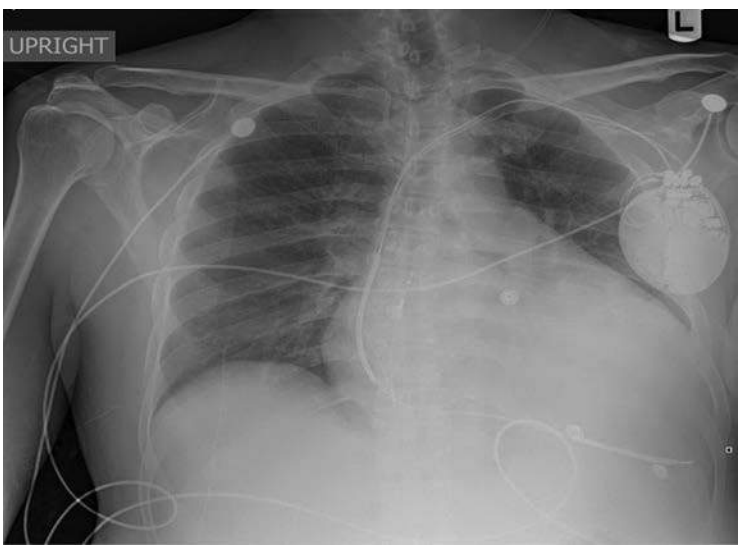

Figure 3.1a

3.2. An 84-year-old male was admitted with shortness of breath. He was diagnosed with left pleural effusion. He underwent thoracentesis. A few hours later he developed increasing oxygen requirements. A chest X-ray was done (see Figure 3.2a). What does it show?

A. Pulmonary edema
B. Right apical pneumothorax
C. Left apical pneumothorax
D. Right-sided pneumonia

Cardiology Board Review, First Edition. Ramdas G. Pai, Padmini Varadarajan and Sudha M. Pai.

Figure 3.2a

3.3. A 59-year-old male was admitted with a history of subarachnoid hemorrhage. A PA chest X-ray (Figure 3.3a) was performed in the ER. What does the chest X-ray show?

A. Normal chest X-ray

B. Prosthetic valve in the mitral position

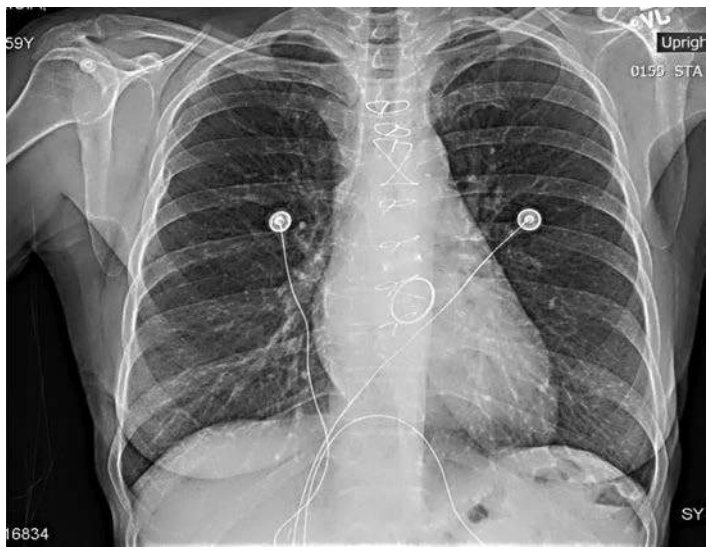

Figure 3.3a

C. Prosthetic valve in the aortic position
D. Prosthetic valves in the aortic and mitral positions

3.4. A 75-year-old male presented to the ER with complaints of shortness of breath. A chest X-ray (Figure 3.4a) was performed in the ER. What does the X-ray show?
A. Left pleural effusion
B. Right pleural effusion
C. Consolidation
D. Pulmonary edema

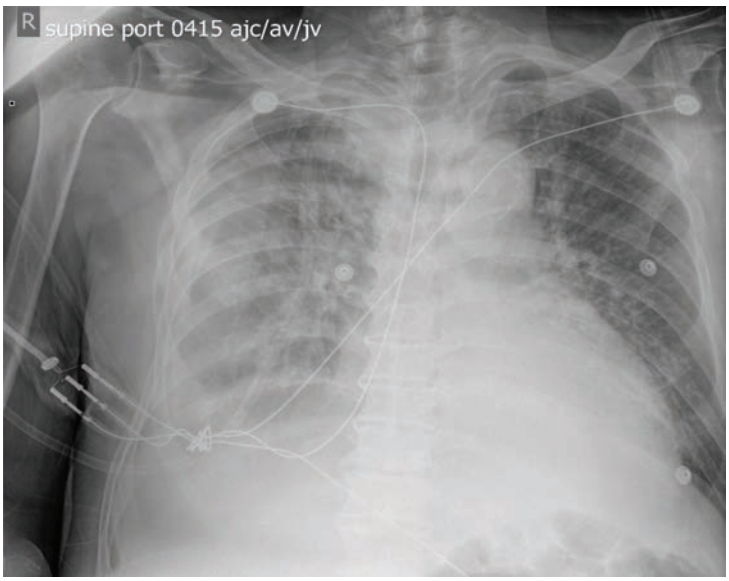

Figure 3.4a

3.5. A 59-year-old Pakistani male presented to the ER with complaints of headache. He had a computed tomography (CT) scan of his head, which showed evidence of subdural hemorrhage. He also had a chest X-ray (Figure 3.5a) in the ER. What does the X-ray show?
A. Bioprosthetic valve in the aortic position
B. Bileaflet mechanical prosthesis in the mitral position
C. Bioprosthetic valve in the mitral position
D. No prosthetic valve is seen

3.6. A 56-year-old male presented to the ER with complaints of shortness of breath on exertion, cough with whitish expectoration, and pedal edema. In the ER he had a chest X-ray (see Figure 3.6a). What is the most important finding on the X-ray?
A. Pneumothorax
B. Right pleural effusion only
C. Left pleural effusion
D. Bilateral pleural effusion
E. No abnormality seen

Figure 3.5a

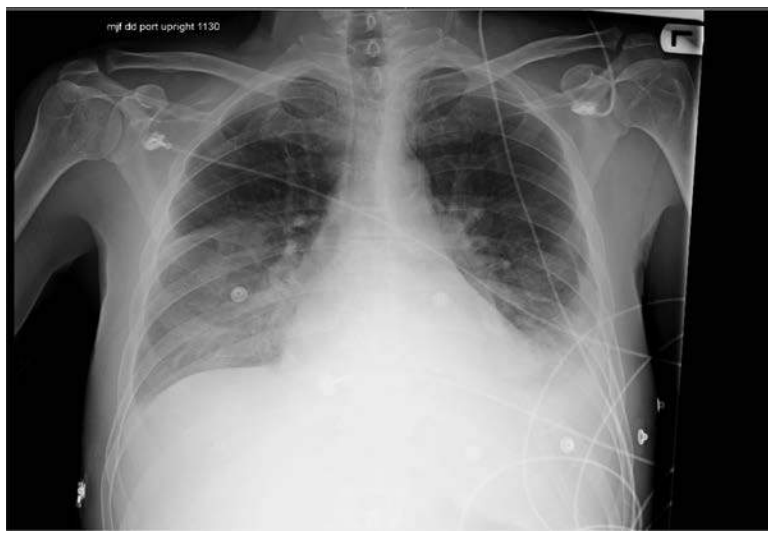

Figure 3.6a

3.7. A 39-year-old male presented to the hospital after a cardiac arrest at home. He was brought to the hospital and had a chest X-ray (Figure 3.7). What does the chest X-ray show?

A. Normal heart size
B. Cardiomegaly
C. Left pneumothorax
D. Right pneumothorax

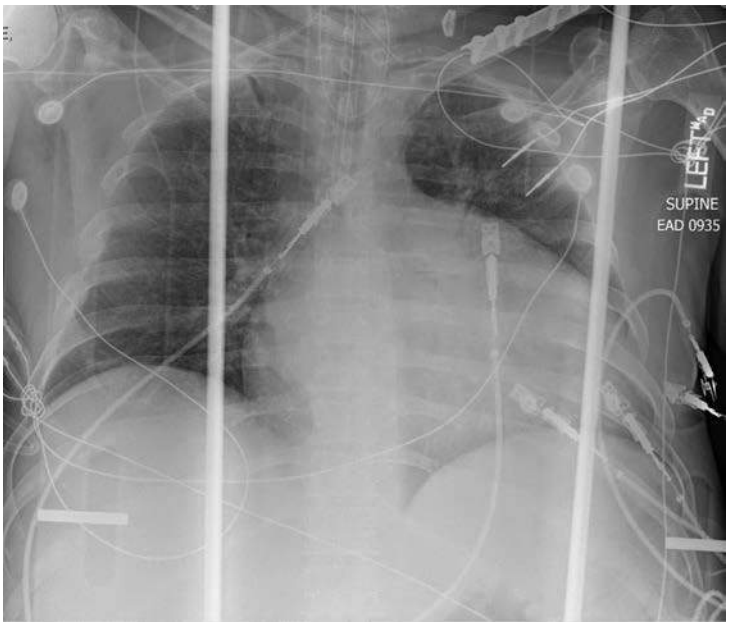

Figure 3.7

3.8. A 51-year-old male came to the hospital with complaints of fatigue, cough. He had a chest X-ray (see Figure 3.8a) in the ER. What does his chest X-ray show?

A. Normal aortic size
B. Prominent aortic knob
C. Prominent main pulmonary artery
D. Prominent left bronchus

3.9. The patient in Question 3.8 then had an echocardiogram. He had mild tricuspid regurgitation, velocity of 4.7 m/s, elevated right atrial pressure of 20 mmHg, and estimated pulmonary artery systolic pressure of 110 mmHg. What are these findings suggestive of?

A. Primary pulmonary hypertension
B. Pulmonary vascular congestion
C. Right to left shunt
D. None of the above

3.10. A 69-year-old male was admitted to the hospital complaining of shortness of breath. His initial chest X-ray showed pulmonary edema and he was started on intravenous diuretics. Two days later he complained of feeling feverish,

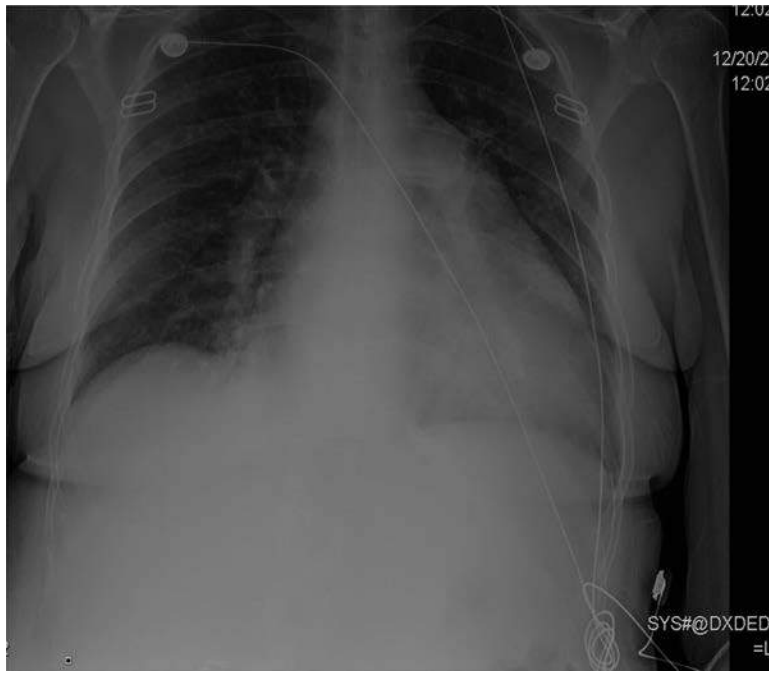

Figure 3.8a

temperature was 101°F, with chills and greenish expectoration. What does the repeat chest X-ray (Figure 3.10a) show?

A. Pulmonary edema
B. Right hilar consolidation with superimposed pulmonary vascular congestion
C. Left hilar consolidation
D. Right hilar consolidation

3.11. A 62-year-old male was admitted with complaints of shortness of breath. What does the chest X-ray in Figure 3.11a show?

A. Left atrial enlargement
B. Right ventricular enlargement
C. Left ventricular enlargement
D. Right atrial and right ventricular enlargement

3.12. An 80-year-old female patient has a history of long-standing systolic murmur at the base. She had a chest X-ray (Figure 3.12a). What is the most important finding?

A. Marked enlargement of main pulmonary artery
B. Marked enlargement of the aorta
C. Marked enlargement of the right pulmonary artery
D. Marked enlargement of the main pulmonary artery and left pulmonary artery

3.13. What does the blue arrow point to on the chest X-ray in Figure 3.13?

A. Enlarged left atrium
B. Aortic knob
C. Enlarged pulmonary artery
D. None of the above

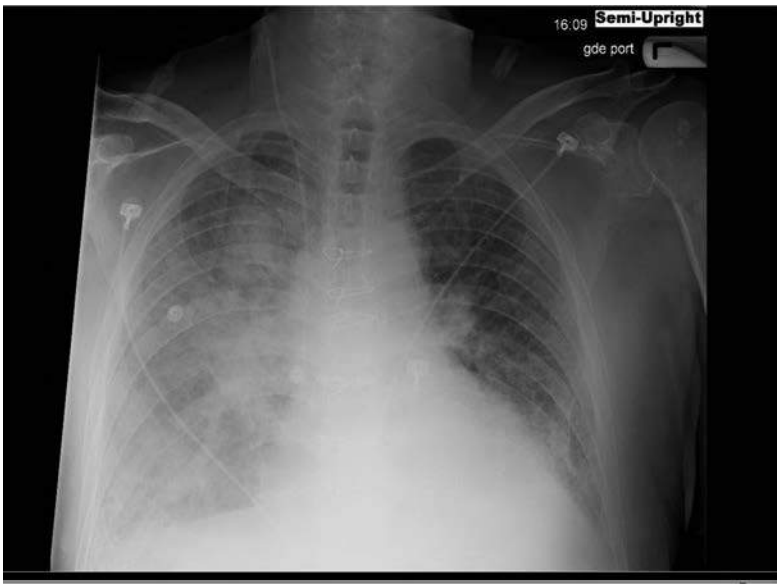

Figure 3.10a

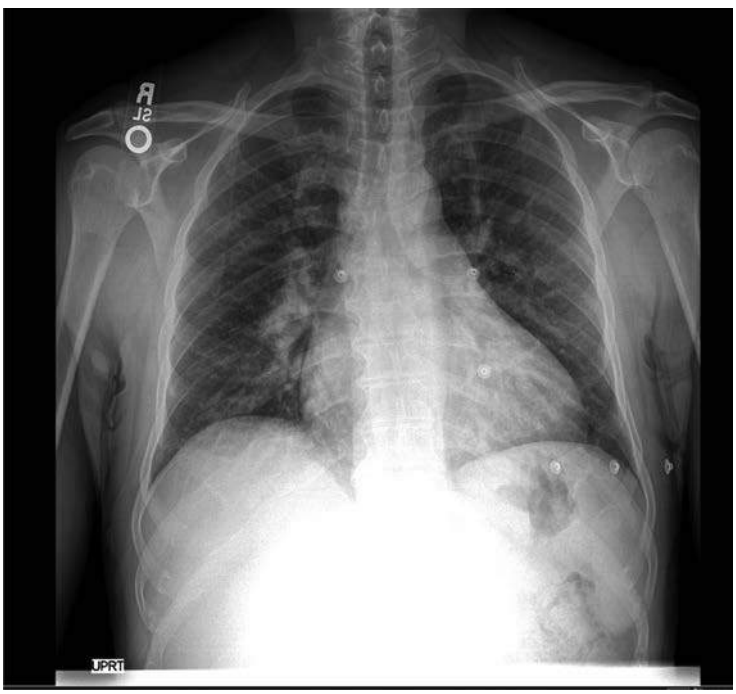

Figure 3.11a

Figure 3.12a

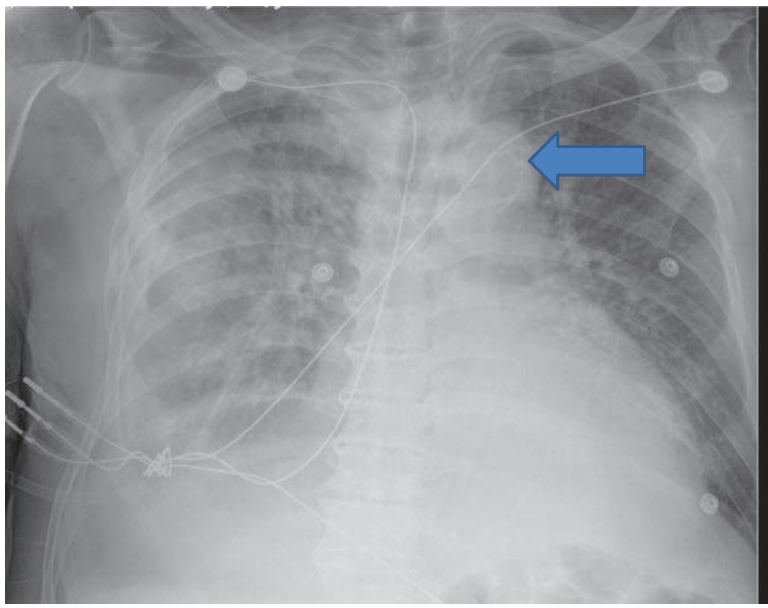

Figure 3.13

3.14. What structure indicated by the blue arrow in Figure 3.14 forms the cardiac boundary:

A. Ascending aorta
B. Arch of the aorta
C. Right pulmonary artery
D. Superior vena cava

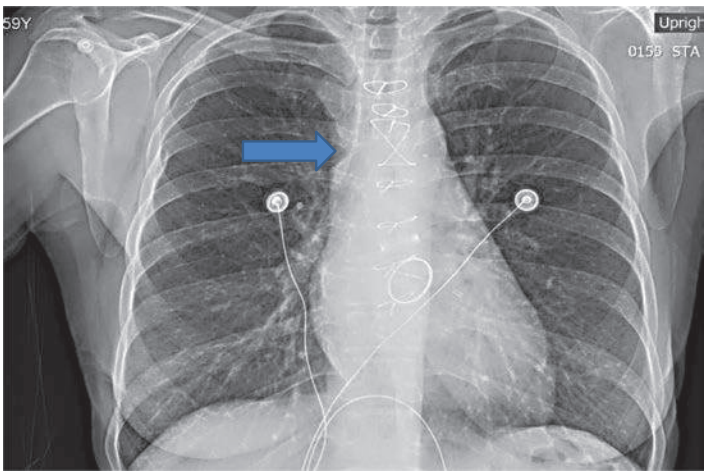

Figure 3.14

3.15. Figure 3.15a shows a 93-year-old female patient with a history of shortness of breath who has undergone what procedure?

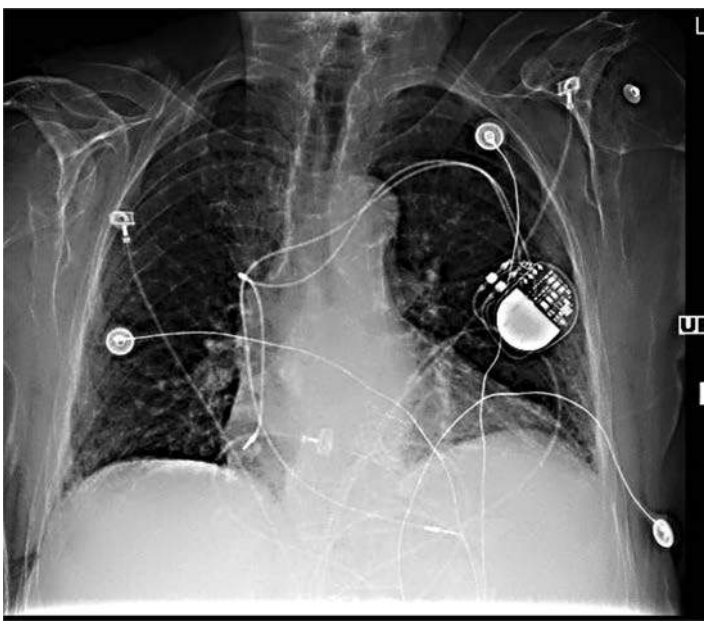

Figure 3.15a

A. Surgical replacement of mitral valve
B. Surgical replacement of aortic valve
C. Transaortic valve replacement (TAVR)
D. None of the above

3.16. The patient in Question 3.15 has also undergone another procedure. What is this other procedure?
A. Permanent single-chamber pacemaker
B. Dual-chamber pacemaker
C. Dual-chamber AICD
D. None of the above

3.17. What does the blue arrow in Figure 3.17 point to?
A. Right atrial pacer lead
B. Right ventricular pacer lead
C. Right ventricular implantable cardioverter-defibrillator (ICD) lead
D. Coronary sinus lead

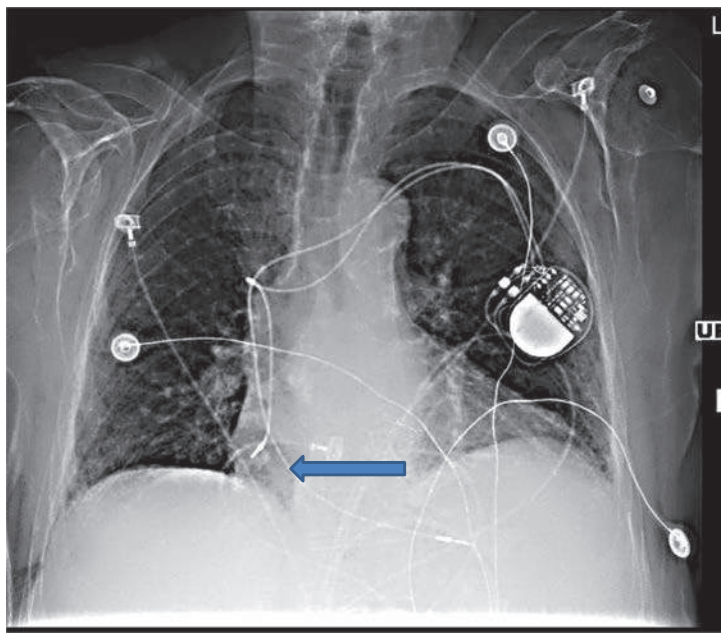

Figure 3.17

3.18. What does the blue arrow in Figure 3.18 point to?
A. Right atrial pacer lead
B. Right ventricular ICD lead
C. Right atrial ICD lead
D. Coronary sinus lead

3.19. What does the blue arrow in Figure 3.19a point to?
A. Right atrial pacer lead
B. Right ventricular ICD lead
C. Right atrial ICD lead
D. Coronary sinus lead

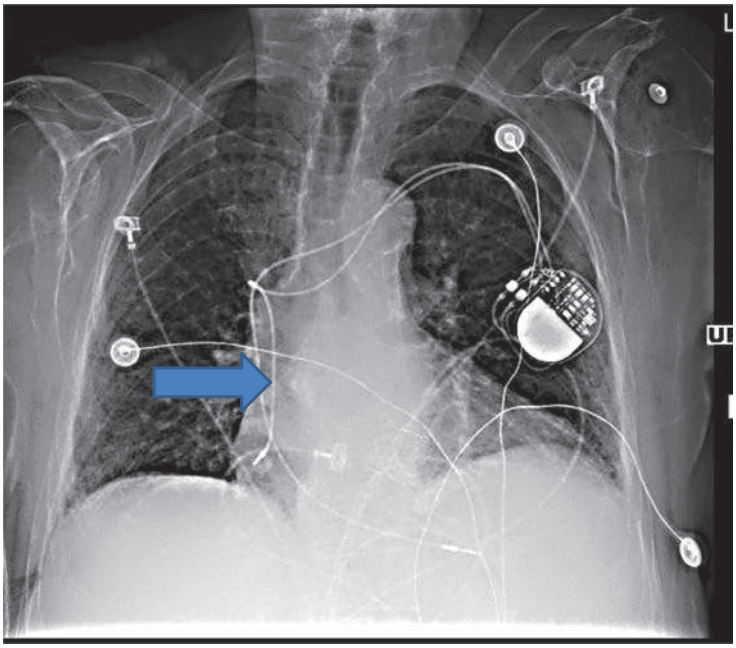

Figure 3.18

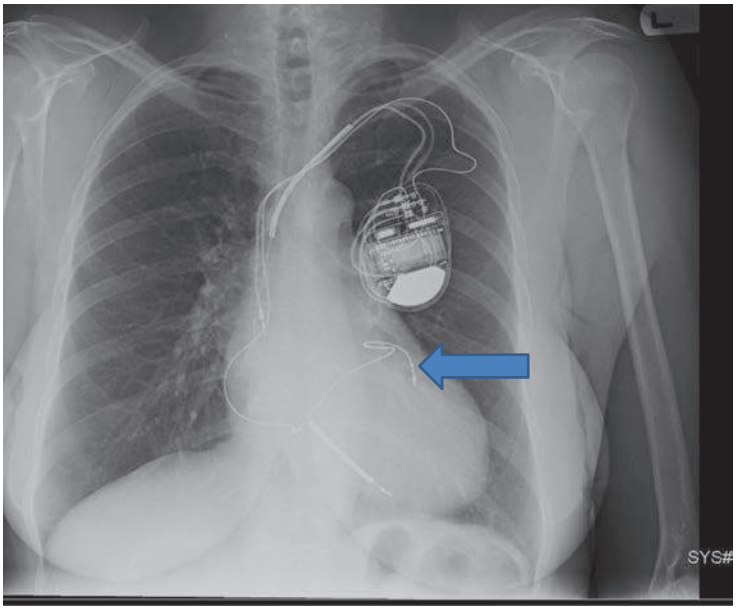

Figure 3.19a

3.20. What does the blue arrow in Figure 3.20 point to?

A. A pacer lead
B. Catheter placed through left subclavian vein
C. Arterial line
D. None of the above

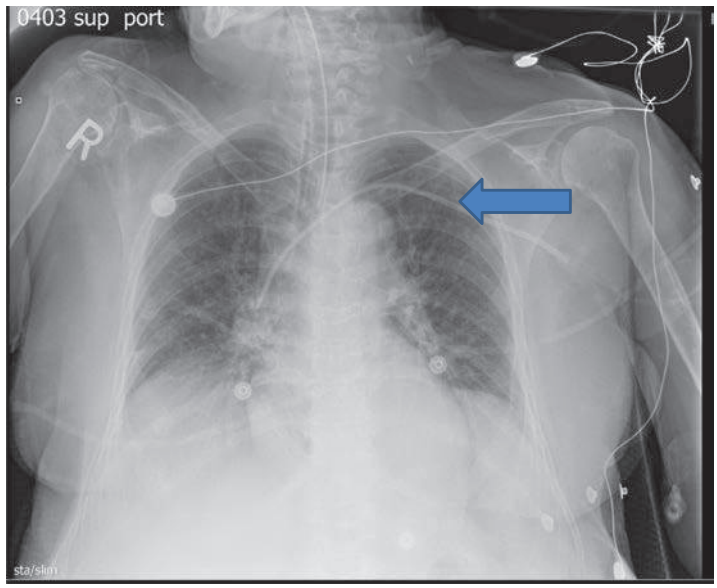

Figure 3.20

3.21. What does the blue arrow in Figure 3.21 point to?

A. Catheter placed through right internal jugular vein
B. Catheter through right subclavian vein
C. Pacer lead
D. None of the above

3.22. An 86-year-old male with history of chronic obstructive pulmonary disease is admitted to the hospital. After a day he was noted to be hypoxic. He also complained of feeling feverish and increasingly short of breath. Referring to Figure 3.22a, what procedure did he undergo?

A. Placement of central line
B. Placement of a pacer
C. Endotracheal intubation
D. Thoracentesis

3.23. The arrow in Figure 3.23 points to which landmark on the chest X-ray from the patient in Question 3.22?

A. Carina
B. Main pulmonary artery
C. Esophagus
D. Aorta

3.24. The arrow in Figure 3.24 points to what structure on the chest X-ray?

A. Nasogastric tube
B. Percutaneous endoscopic gastrostomy tube
C. Central venous catheter
D. None of the above

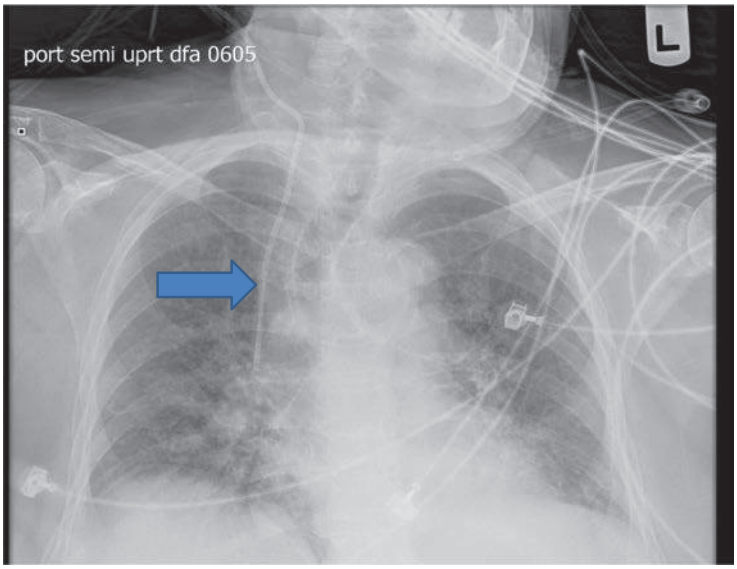

Figure 3.21

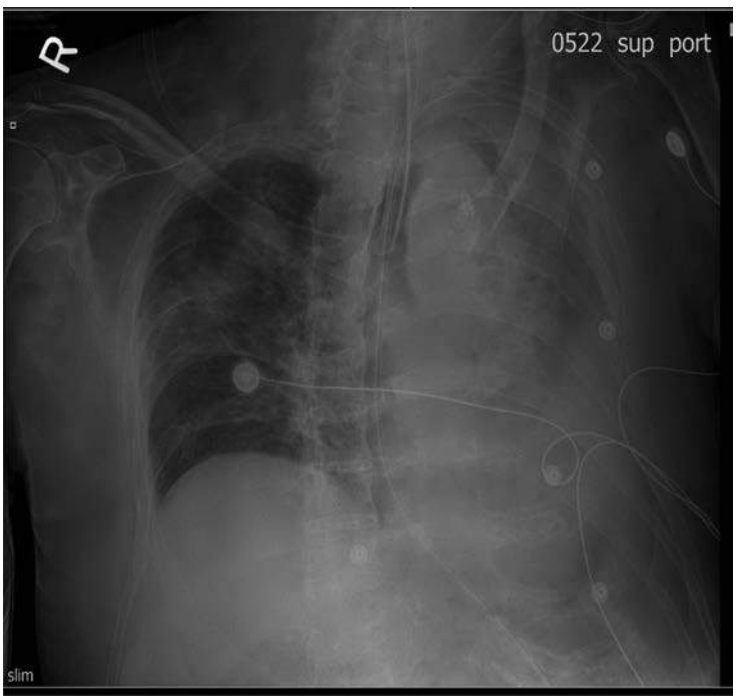

Figure 3.22a

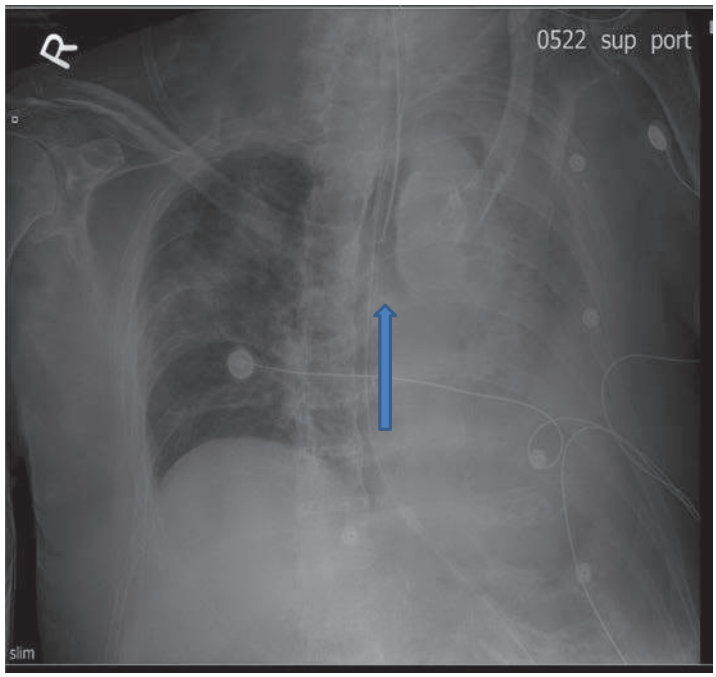

Figure 3.23

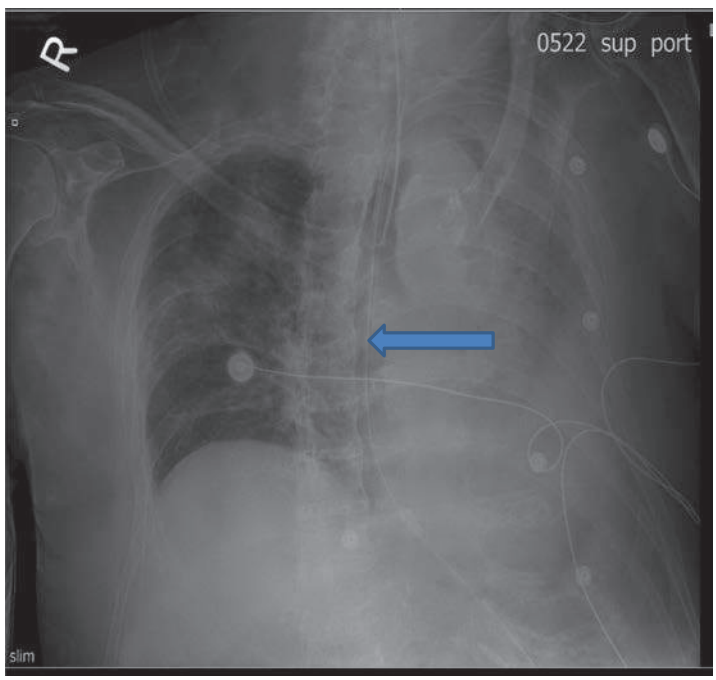

Figure 3.24

3.25. A 59-year-old Hispanic female patient was admitted to the hospital with complaints of fever and shortness of breath. A chest X-ray was performed (see Figure 3.25a) and she had which of the following procedures performed?

A. Pericardiocentesis
B. Placement of a catheter in the right pleural space
C. Placement of a catheter in the left pleural space
D. Right paracentesis

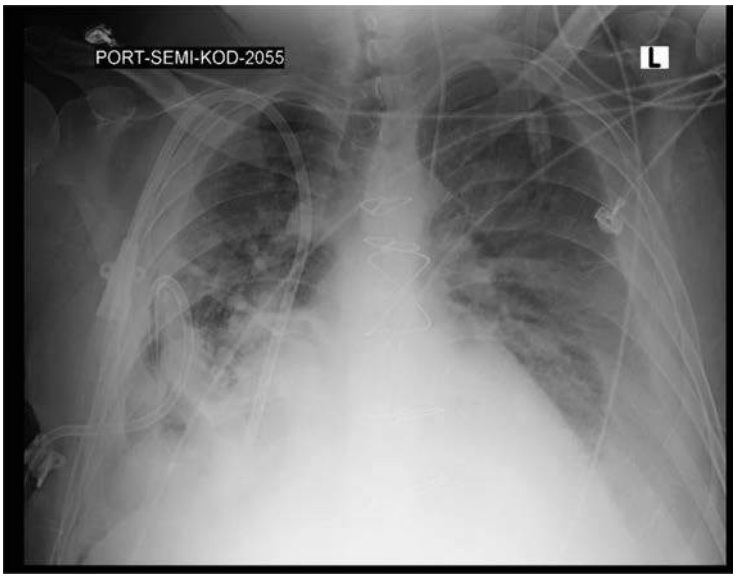

Figure 3.25a

3.26. The chest X-ray in Figure 3.26a shows which of the following:

A. Dextroposition
B. Dextrocardia
C. Levocardia
D. Mesocardia

3.27. A 69-year-old male with a history of heart transplant 10 years ago is complaining of low-grade fever, fatigue, and loss of appetite. He had a chest X-ray (see Figure 3.27a) as part of his work up. What does this chest X-ray show?

A. Normal chest X-ray
B. A rounded opacity in the right lower lobe
C. Patchy consolidation in the left lower lobe
D. Multiple lung nodules

3.28. Plethoric lung fields on chest X-ray are seen in all of the following except:

A. ASD
B. Ventricular septal defect (VSD)
C. Patient ductus arteriosus (PDA)
D. Mitral stenosis

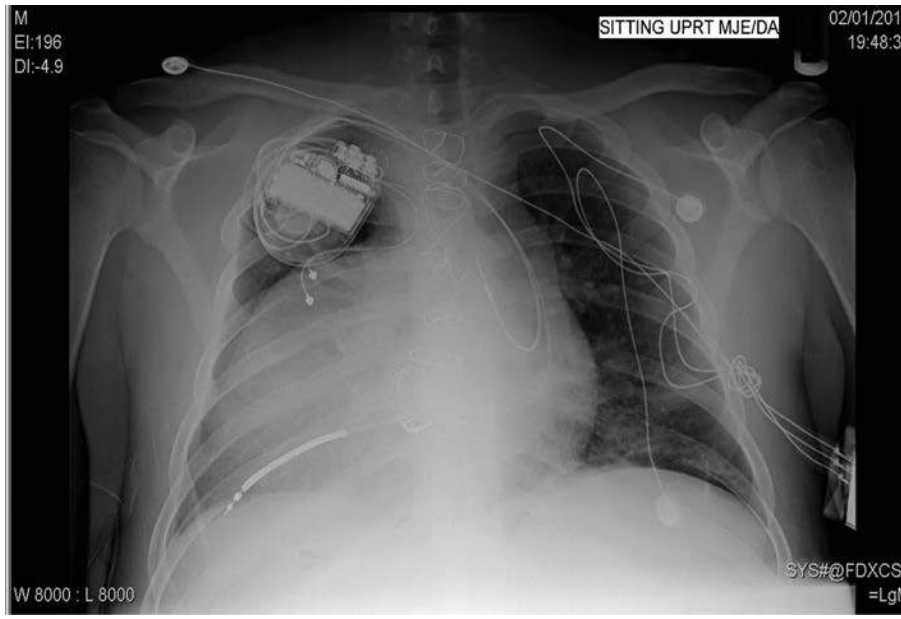

Figure 3.26a

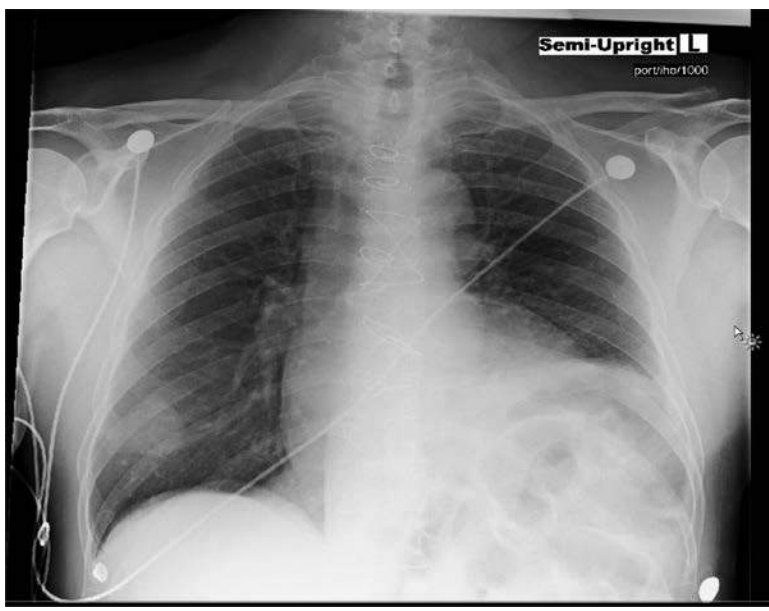

Figure 3.27a

3.29. What is peripheral pulmonary artery pruning a feature of?
- **A.** Pulmonary hypertension
- **B.** Pulmonary stenosis
- **C.** Acute pulmonary embolism
- **D.** Pulmonary regurgitation

3.30. Dilated main pulmonary artery (jug handle appearance) in a patient with Eisenmenger's syndrome is indicative of:
- **A.** ASD Eisenmenger's
- **B.** VSD Eisenmenger's
- **C.** PDA Eisenmenger's

3.31. Straightened left heart border is classically seen in which of the following:
- **A.** Mitral stenosis
- **B.** Aortic stenosis
- **C.** ASD
- **D.** PDA

3.32. Coeur en Sabot is a feature of which of the following:
- **A.** Tetralogy of Fallot
- **B.** Aortic coarctation
- **C.** Dilated cardiomyopathy
- **D.** Hypertrophic cardiomyopathy

3.33. Snowman appearance is a classic description of which of the following:
- **A.** Partial anomalous pulmonary venous drainage
- **B.** Total anomalous pulmonary venous drainage
- **C.** Ebstein's anomaly
- **D.** ASD

3.34. Scimitar sign is seen in which of the following:
- **A.** Partial anomalous pulmonary venous drainage
- **B.** Total anomalous pulmonary venous drainage
- **C.** Ebstein's anomaly
- **D.** ASD

3.35. An increase in subcarinal angle due to lifting of left bronchus is a feature of which of the following:
- **A.** Left ventricular hypertrophy
- **B.** Left atrial dilation
- **C.** Right atrial dilation
- **D.** Pulmonary ectasia

Answers

3.1. D. Cardiomegaly, AICD lead, left pleural effusion.

The cardiomediastinal ratio is increased, which is indicative of cardiomegaly (red arrow in Figure 3.1b). There is also an AICD lead in the right ventricle (blue arrow in Figure 3.1b). The left costophrenic angle is blunted, which is suggestive of presence of pleural effusion.

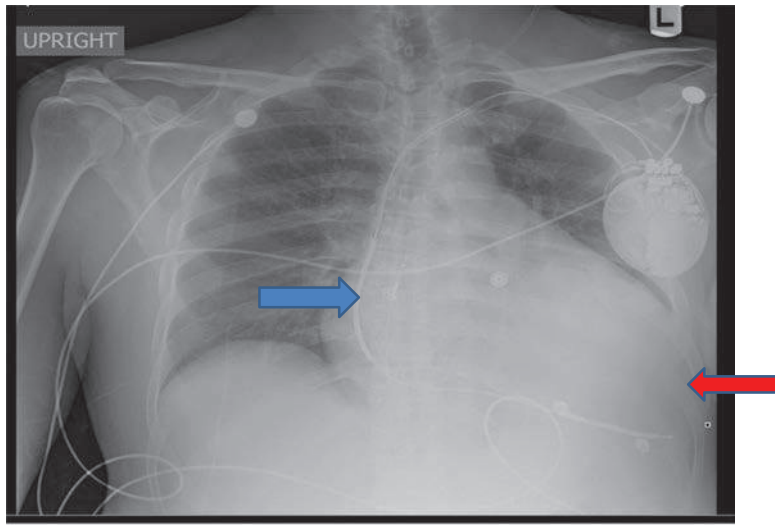

Figure 3.1b

3.2. C. Left apical pneumothorax.

The patient had thoracentesis, which then caused left apical pneumothorax: blue arrow in lateral view (Figure 3.2b); multiple arrows in posteroanterior (PA) view (Figure 3.2c). The pneumothorax was drained with a chest tube.

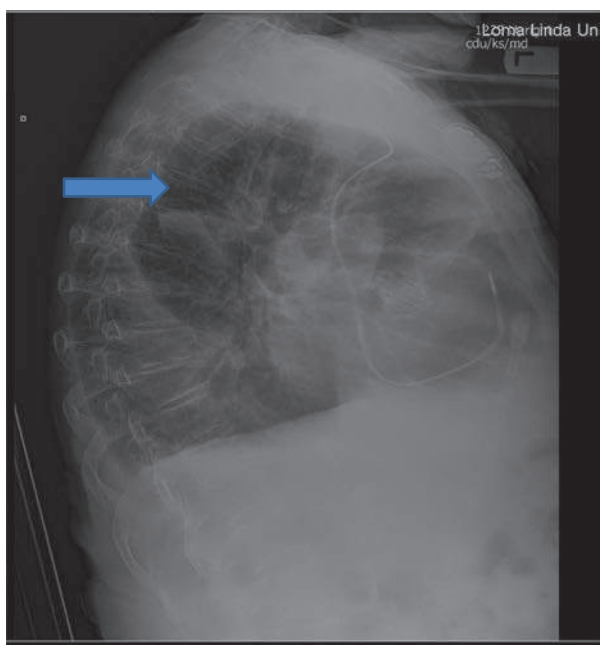

Figure 3.2b

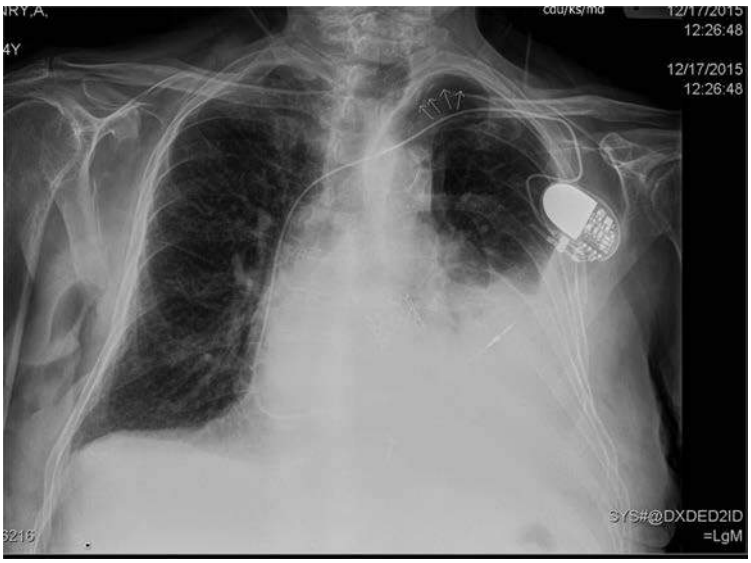

Figure 3.2c

3.3. D. Prosthetic valves in the aortic and mitral positions

The chest X-rays (Figures 3.3b and 3.3c) show two mechanical valve prosthetic rings: one in the aortic (red arrow) and another in the mitral position (blue arrow). Mitral is to the left of the midline, caudal and posterior.

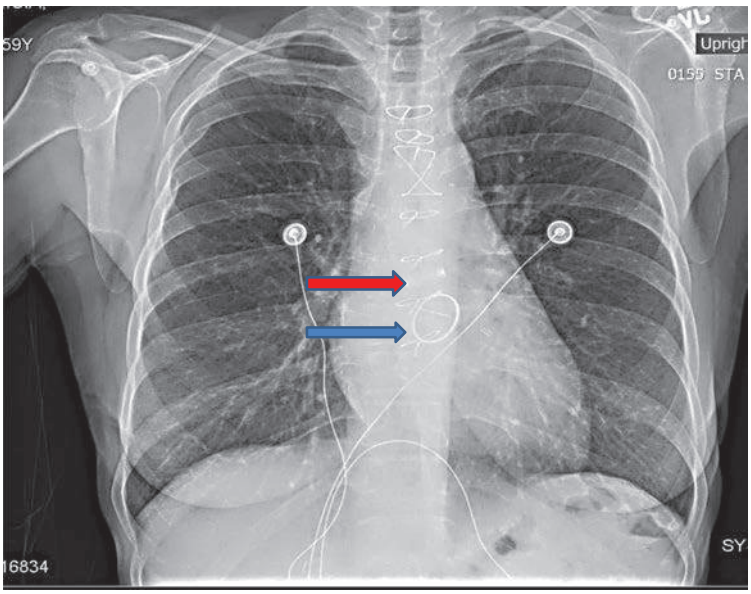

Figure 3.3b

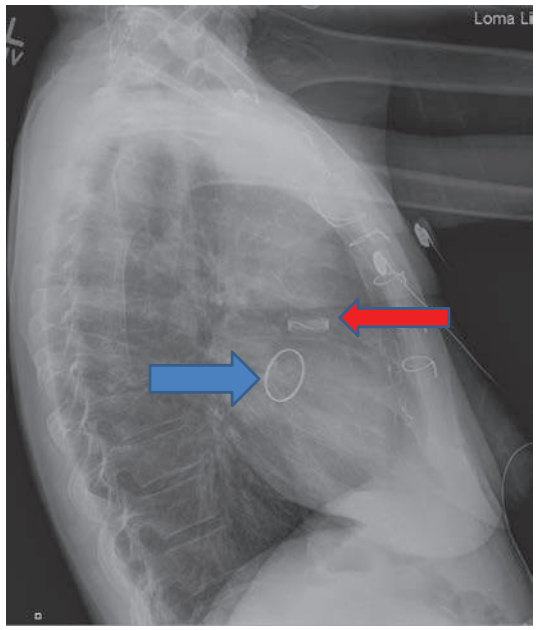

Figure 3.3c

3.4. B. Right pleural effusion.

The right costophrenic angle is blunted. The lower to middle lung zones are indistinct and markings are obscured. The chest X-ray shows the presence of right pleural effusion, shown by the blue arrow in Figure 3.4b.

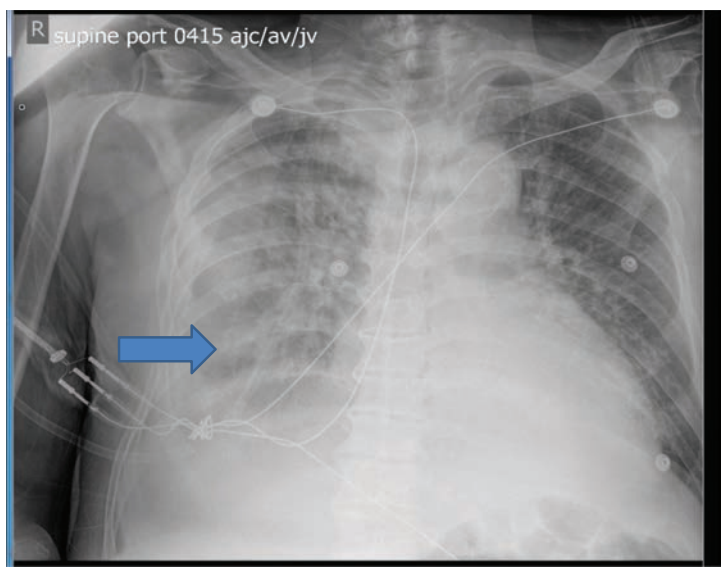

Figure 3.4b

3.5. B. Bileaflet mechanical prosthesis in the mitral position.

The chest X-ray shows sternal wires indicative of previous surgery (red arrow in Figure 3.5b). There is a bileaflet mechanical prosthesis in the mitral position (blue arrow in Figure 3.5b). The patient's international normalized ratio was 13 and probably caused the subdural hemorrhage.

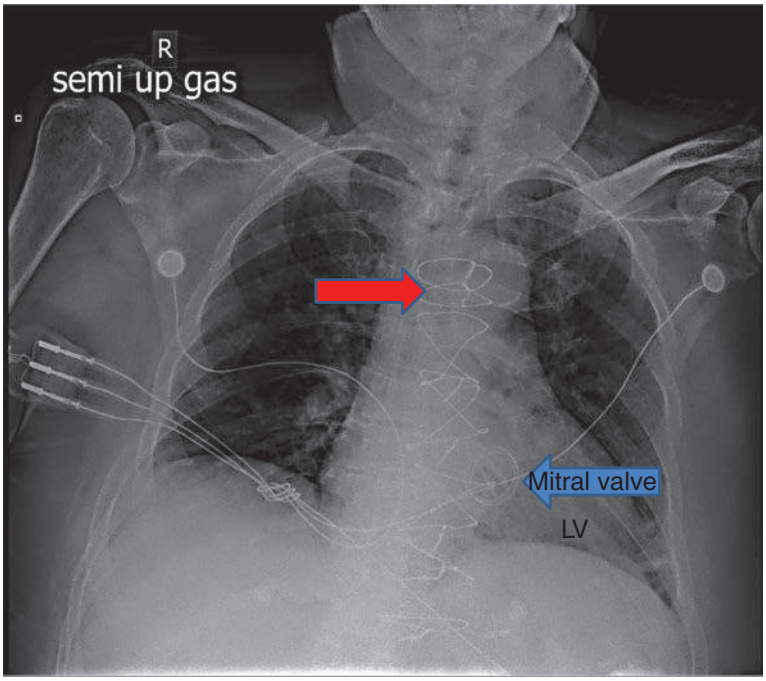

Figure 3.5b

3.6. D. Bilateral pleural effusion.

The chest X-ray shows blunting of both costophrenic angles, which is indicative of bilateral pleural effusion (blue arrows in Figure 3.6b).

3.7. B. Cardiomegaly.

The patient's chest X-ray shows increased cardiomediastinal ratio, which is suggestive of cardiomegaly.

3.8. C. Prominent main pulmonary artery.

The main pulmonary artery is enlarged and is prominent (blue arrow in Figure 3.8b). The red arrow points to the left pulmonary artery, which has a pruned appearance in the peripheral lung zones.

3.9. A. Primary pulmonary hypertension.

The patient is young, and has a prominent main pulmonary artery on the chest X-ray. His echocardiogram reveals pulmonary hypertension. The lungs fields are not plethoric. Given the findings on chest X-ray and echocardiogram, he has primary pulmonary hypertension.

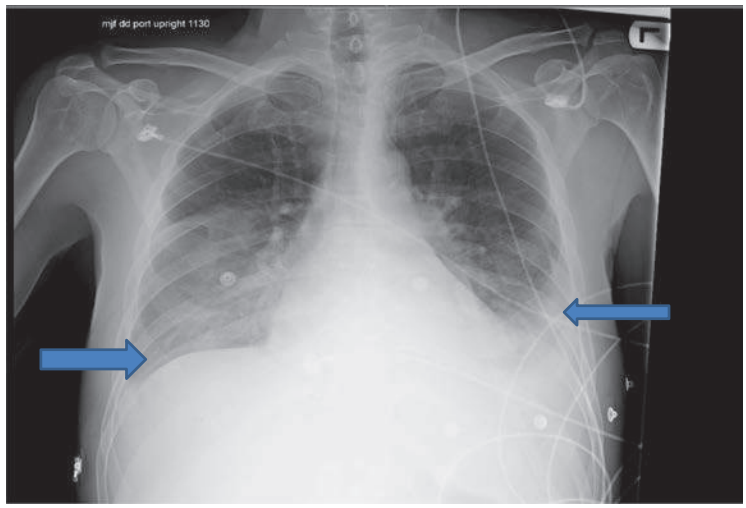

Figure 3.6b

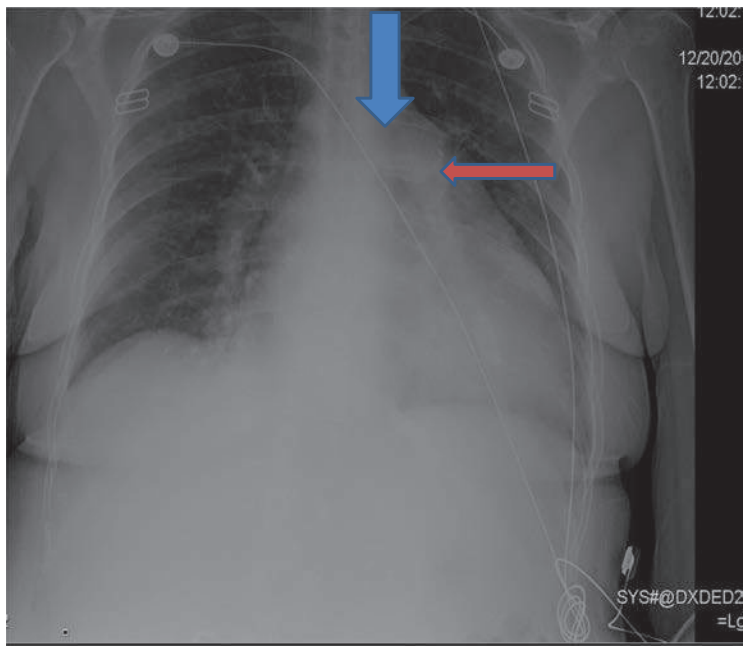

Figure 3.8b

3.10. B. Right hilar consolidation with superimposed pulmonary vascular congestion.

The chest X-ray shows increased pulmonary vascular congestion. But the more striking finding is the presence of right hilar consolidation (blue arrow in Figure 3.10b) suggestive of pneumonia. The less likely differential diagnosis is unilateral right pulmonary edema.

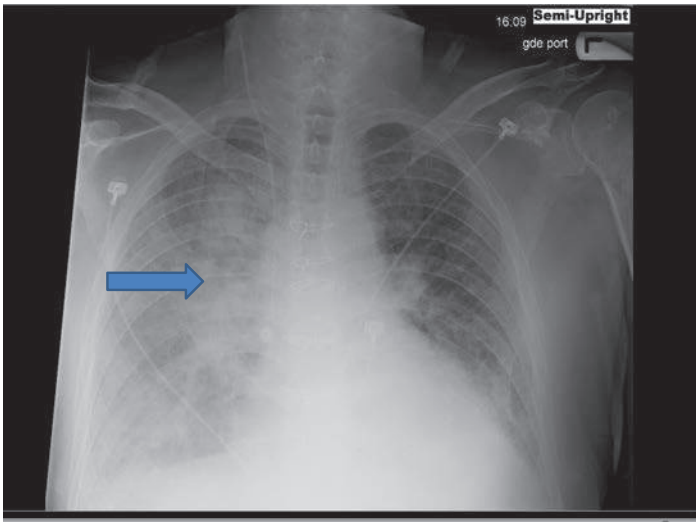

Figure 3.10b

3.11. D. Right atrial and right ventricular enlargement.

This patient's chest X-ray shows enlargement of both right atrium (blue arrow in Figure 3.11b) and right ventricle, as evidenced by lifted apex (red arrow). Enlargement of the right ventricle usually causes the apex to be rounded and uplifted,

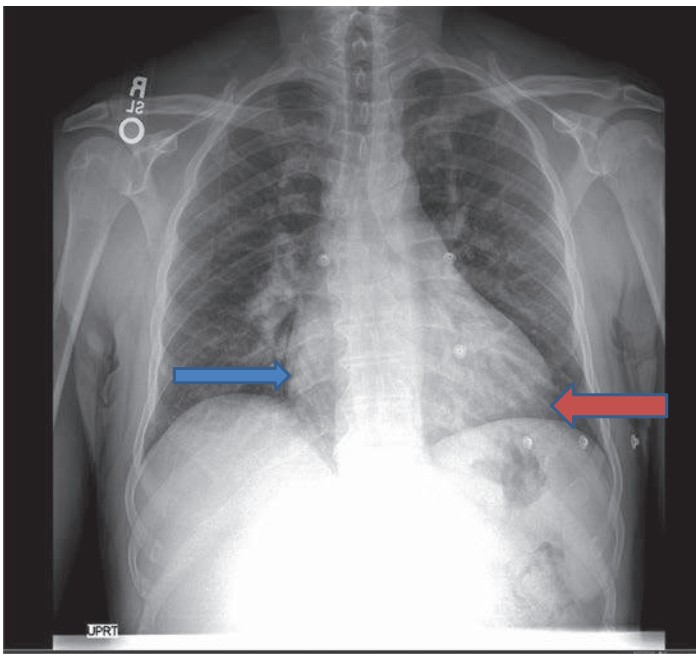

Figure 3.11b

as shown by the red arrow. This patient had an echocardiogram which showed enlargement of the right-sided chambers without any signs of a shunt. He then underwent a transesophageal echocardiogram, which revealed a sinus venosus atrial septal defect (ASD).

3.12. D. Marked enlargement of the main and left pulmonary artery.

In Figure 3.12b, the red arrow points to the enlarged main pulmonary artery and the blue arrow points to the enlarged left pulmonary artery. This is suggestive of pulmonary valve stenosis.

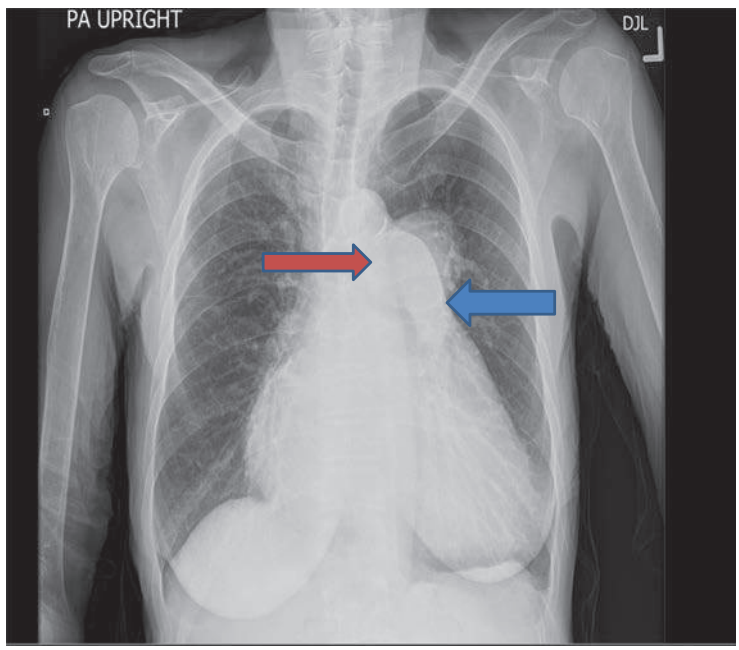

Figure 3.12b

3.13. B. Aortic knob.

3.14. D. Superior vena cava.

3.15. C. Transaortic valve replacement.

This patient with complaints of shortness of breath had severe aortic stenosis. She then underwent a transaortic valve replacement. The bioprosthetic valve is shown by the blue arrow in Figure 3.15b. This is an Edwards valve and has a titanium mesh to hold the leaflets and not just the sewing ring. Also note that there are no sternotomy wires.

3.16. B. Dual-chamber pacemaker.

3.17. B. Right ventricular pacer lead.

3.18. A. Right atrial pacer lead.

This patient has a dual-chamber pacemaker with leads in the right atrium and right ventricle.

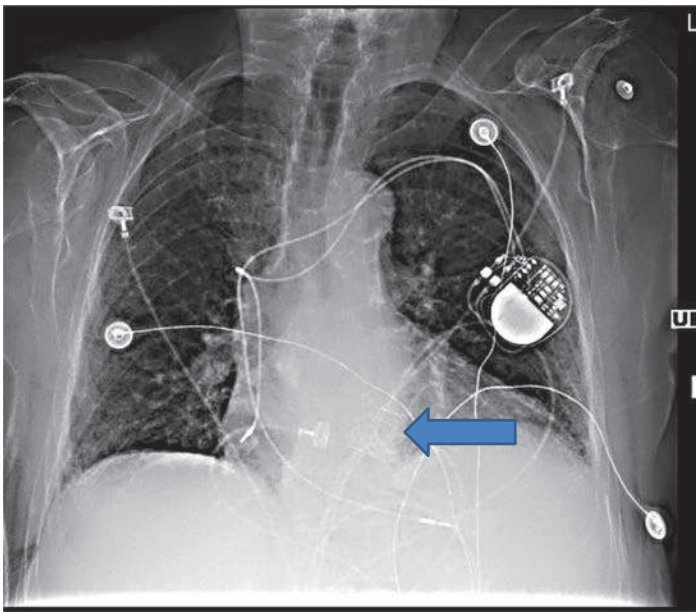

Figure 3.15b

3.19. D. Coronary sinus lead.

In this patient's chest X-ray three leads are visible. In Figure 3.19b, the blue arrow points to the coronary sinus lead. The lead in the right ventricle is thicker than a regular pacing lead and is indicative of an ICD lead (red arrow). The third lead is the right atrial lead (yellow arrow).

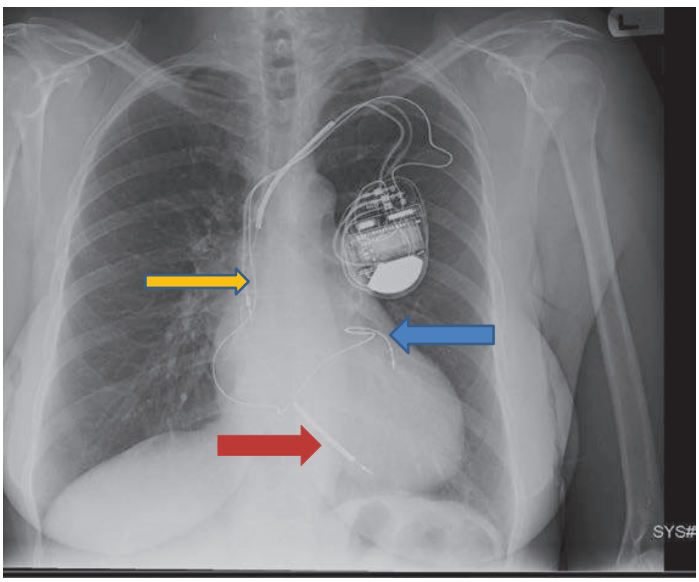

Figure 3.19b

3.20. B. Catheter placed through left subclavian vein.

There is a catheter that has been placed through a left subclavian approach and is terminating at the lower level of the superior vena cava.

3.21. A. Catheter placed through right internal jugular vein.

3.22. C. Endotracheal intubation.

The patient was tachypneic and hypoxic. He had emergent endotracheal intubation and was started on mechanical ventilation. The blue arrow in Figure 3.22b points to the endotracheal tube.

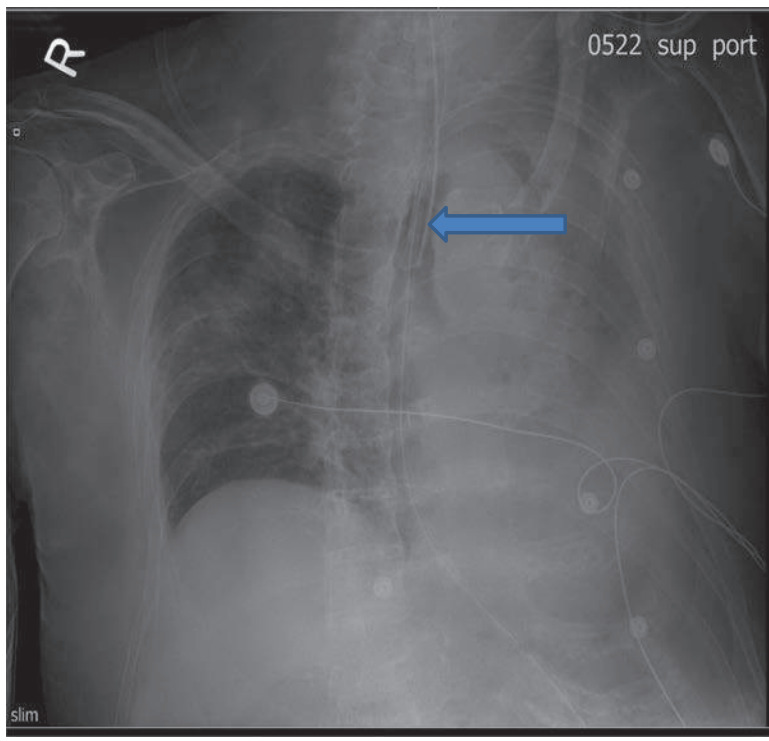

Figure 3.22b

3.23. A. Carina.

The endotracheal tube can be seen terminating about 1 cm above the carina.

3.24. A. Nasogastric tube.

The arrow points to the nasogastric tube, which is terminating below the diaphragm.

3.25. B. Placement of a catheter in the right pleural space.

The arrow in Figure 3.25b points to the catheter in the right pleural space. The right costophrenic angle is still obscured. She probably had right pleural effusion that was drained by placement of a right pleural catheter.

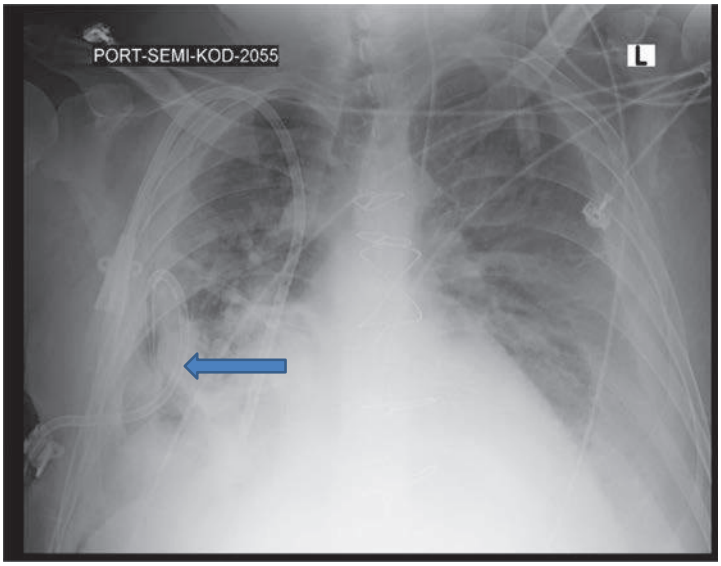

Figure 3.25b

3.26. B. Dextrocardia.

This is a portable chest X-ray. The most striking feature is that the apex of the heart is pointing to the right. This is called dextrocardia. In dextroposition, the apex still points to the left but the heart itself is shifted to the right. The arrow in Figure 3.26b points to the apex of the heart, which is pointing to the right.

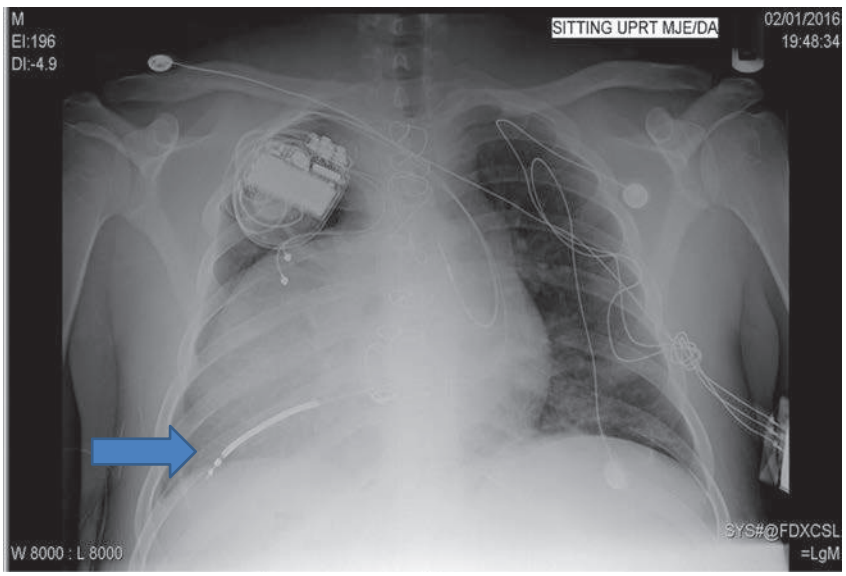

Figure 3.26b

3.27. B. A rounded opacity in the right lower lobe.

The rounded opacity in the right lower lobe is shown by the arrow in Figure 3.27b. Since this patient is status post heart transplant, he is prone to opportunistic infections such as aspergillosis, norcardiosis, and coccidiomycosis. He underwent a CT scan of the lung which again demonstrated the rounded opacity in the right lower lobe. He underwent CT-guided biopsy and pathology was positive for *Norcardia*. Also note the elevated left hemidiaphragm, which may suggest left phrenic nerve palsy.

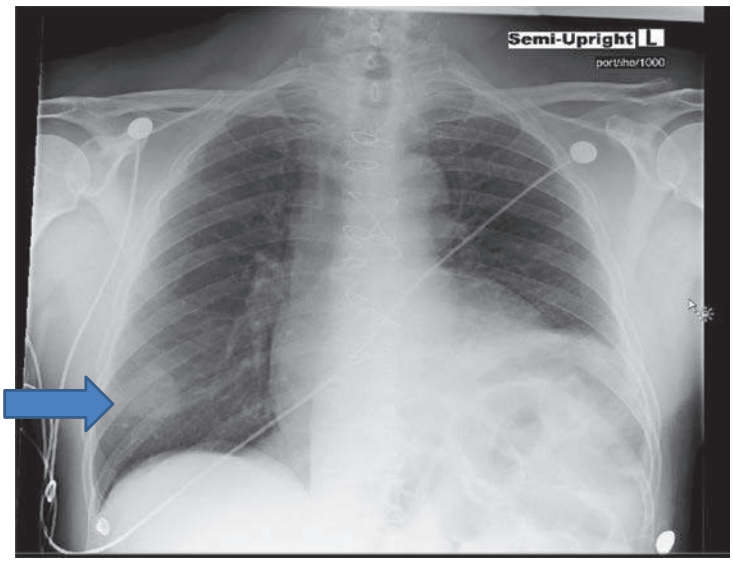

Figure 3.27b

3.28. D. Mitral stenosis.

Plethoric lung fields are indicative of increased pulmonary blood flow and are seen in left-to-right shunts such as ASD, VSD, and PDA. The pulmonary artery branches are prominently seen up to peripheral lung fields and flow is significantly increased.

3.29. A. Pulmonary hypertension.

Peripheral vasoconstriction, along with dilated central pulmonary arteries, results in this appearance in pulmonary hypertension. In pulmonary stenosis, lung fields are oligemic.

3.30. A. ASD Eisenmenger's.

Severely dilated main pulmonary artery is a feature of large ASD. In large VSDs, as pulmonary artery pressure does not regress during childhood, pulmonary artery tends to have thicker walls and hence does not dilate as much.

3.31. A. Mitral stenosis.

Filling of the bay between main pulmonary artery and left ventricle by the dilated left atrial appendage in mitral stenosis causes straightening of left heart border.

3.32. A. Tetralogy of Fallot.

This is due to right ventricular hypertrophy, which lifts the apex up mimicking the wooden boots of Danish farmers.

3.33. B. Total anomalous pulmonary venous drainage.

3.34. A. Partial anomalous pulmonary venous drainage.

Partial anomalous pulmonary venous drainage from right upper pulmonary vein to inferior vena cava results in a scimitar-shaped shadow along right heart border. Diagnosis is confirmed by transesophageal echocardiography.

3.35. B. Left atrial dilation.

This is typically seen in mitral stenosis due to severe left atrial enlargement. Dilated left atrium may also show as a double atrial shadow near right atrial border with acute angulation with right hemidiaphragm, pressure on left recurrent laryngeal nerve causing hoarseness of voice (Ortner's syndrome), and dysphagia due to pressure on esophagus. Pressure on esophagus is best appreciated by performing a barium swallow.

Stress Testing and Risk Stratification of Asymptomatic Subjects

4

4.1. A 45-year-old male comes to your office for evaluation of chest pain. He reports substernal chest pressure, lasts a few minutes, does not radiate to his shoulder or jaw, occurs with exertion sometimes, and is relieved on its own in a few minutes. His risk factors include hypertension controlled on hydrachlorothiazide and amlodipine. He also was a 20 pack a year smoker, but quit a month ago. His electrocardiogram (ECG) shows no abnormalities. To evaluate his chest pain, what should the next step be?

A. Coronary angiography
B. Exercise stress echocardiogram
C. Exercise stress test
D. No testing needed at this time

4.2. The patient walked for 5 min on the treadmill (Bruce protocol) and had to stop the test due to substernal chest pressure. His peak stress blood pressure (BP) dropped to 90 mmHg from a resting pressure of 130 mmHg. His stress ECG shows 4 mm downsloping ST depressions in the anterior chest leads that last 5 min into recovery. He is nauseous and diaphoretic. What is the next step in his evaluation?

A. Nothing at present
B. Adenosine myocardial perfusion imaging (MPI)
C. Coronary angiogram to evaluate for obstructive CAD
D. Modify medical therapy

4.3. A 55-year-old male comes to your office for evaluation of chest pain. He reports no cardiac risk factors other than hypercholesterolemia. He describes his chest pain as a discomfort, in the central chest, occurs at rest, lasts a few minutes, and is relieved with aspirin. A resting ECG done in the office reveals preexcitation. What does the next step in his evaluation include?

A. Exercise stress test
B. Coronary angiogram
C. Referral to an electrophysiologist
D. Exercise myocardial perfusion

4.4. In the evaluation of a patient with chest pain and right bundle branch (RBBB) on ECG, which of the following is true regarding exercise stress testing?

A. Stress test is not useful in patients with RBBB
B. Stress testing should always be combined with imaging
C. Stress testing can be undertaken without affecting the predictive value of stress ECG
D. None of the above

Cardiology Board Review, First Edition. Ramdas G. Pai, Padmini Varadarajan and Sudha M. Pai.
© 2018 John Wiley & Sons, Ltd. Published 2018 by John Wiley & Sons, Ltd.

4.5. A 50-year-old women presents to the emergency room (ER) with complaints of chest pain. Her chest pain started 3 days prior to presentation and radiates to her jaw, occurs with exertion, and is relieved with rest. Her risk factors include hypertension and hypercholesterolemia. Her ECG at presentation is normal. Three sets of cardiac biomarkers drawn at presentation and then 8 h apart are negative. What is the best next recommended step?

- **A.** She is at low risk for ischemia; hence, discharge her home with advice regarding risk factor modification
- **B.** Refer her for coronary angiography
- **C.** Order a pharmacological stress nuclear study
- **D.** Order an exercise stress test

4.6. Which of the following is not a contraindication to exercise ECG stress testing?

- **A.** 75-year-old male with complaints of chest pain and one episode of frank syncope. On examination, he has slow rising carotid pulse and a harsh 3/6 ejection systolic murmur with radiation to both carotids.
- **B.** A 35-year-old female with complaints of shortness of breath. On examination, jugular venous pressure is elevated, 15 cmH_2O, S3 gallop, and 2+ pedal edema. She has recently delivered her second baby.
- **C.** A 68-year-old male with complaints of chest pain. He describes it as a sharp substernal chest pain, worse on deep inspiration. He gives a history of hip replacement 2 weeks ago.
- **D.** A 44-year-old male with complaints of chest pain brought on by exertion, started a month ago. Physical examination is unremarkable except for an elevated BP of 140/78 mmHg. His ECG shows first-degree atrioventricular block and incomplete RBBB.
- **E.** A 65-year-old male presents to the ER with exertional chest pain. Pain started 24 h prior to presentation. He is currently chest-pain free. His ECG showed sinus bradycardia with Q waves in anterior chest leads V1–V4. An ECG done 1 month ago at his doctor's office was completely normal.

4.7. Which is an indication to stop an exercise treadmill test?

- **A.** Drop of >10 mmHg from baseline BP despite an increase in workload with associated features of ischemia
- **B.** Sustained ventricular tachycardia
- **C.** Moderate to severe angina
- **D.** Signs of cyanosis or pallor
- **E.** All of the above

4.8. Which of the following is a class III indication for exercise stress testing without imaging (echo or nuclear perfusion)?

- **A.** Patients with a high pretest probability of having CAD
- **B.** Preexcitation on baseline ECG
- **C.** Left ventricular hypertrophy with <1 mm ST depression on baseline ECG
- **D.** Patient with vasospastic angina

4.9. A 45-year-old male is being evaluated by his primary care physician as part of his executive health checkup. He reports no risk factors and is asymptomatic. His baseline ECG shows no resting abnormalities. He is able to walk for 14 min (13.5 METS on a Bruce protocol). He reaches an exercise heart rate of 185 bpm, has

no angina, and has no ST segment changes on his ECG. What would his Duke treadmill score be?

A. 9
B. 14
C. 2
D. 3.4

4.10. Based on the test results in Question 4.9, what is the next most appropriate step?

A. Stress imaging study
B. Computed tomography (CT) angiography
C. Coronary angiography
D. No further testing
E. Repeat testing in 1 year

4.11. Which one of the following is a class I recommendation in assessing asymptomatic adults with no known CAD?

A. Genomic testing
B. Obtain global risk score (Framingham)
C. Assessment of lipoprotein and apolipoprotein
D. Measurements of natriuretic peptides

4.12. Which one of the following is a class I recommendation in assessing asymptomatic adults with no known CAD?

A. Genomic testing
B. Obtain family history
C. Assessment of lipoprotein and apolipoprotein
D. Coronary CT angiogram

4.13. Measurement of C-reactive protein (CRP) is not recommended in which of the following?

A. In men over 50 years with a low-density lipoprotein (LDL) of <130 mg/dL
B. In women over 60 years with an LDL <130 mg/dL not on hormone replacement therapy, and without diabetes or chronic kidney disease
C. In asymptomatic high-risk adults
D. In asymptomatic intermediate-risk men 50 years and younger or women 60 years and younger

4.14. With one exception, the following are class III recommendations in assessing low-risk asymptomatic adults with no known history of CAD. Which is the exception?

A. Coronary CT angiogram
B. Magnetic resonance imaging (MRI) for plaque detection
C. Measurement of coronary calcium score
D. Resting ECG

4.15. In patients with diabetes mellitus, which of the following is *not* recommended?

A. Stress echocardiogram
B. Stress MPI
C. Coronary calcium score measurement
D. Measurement of hemoglobin A1C

4.16. In asymptomatic women, all of the following except one are *not* recommended. Which is the exception?

A. Obtaining global risk score
B. Obtaining natriuretic peptides
C. MRI for plaque detection
D. Measurement of lipoprotein

4.17. Stress MPI is recommended in which of the following situations?
A. In the assessment of a low-risk individual
B. In the assessment of an intermediate-risk individual
C. In an asymptomatic adult with diabetes mellitus
D. None of the above

4.18. Which of the following is not true?
A. Echocardiography is recommended to detect left ventricular hypertrophy in patients with hypertension
B. Echocardiography is recommended in risk assessment of asymptomatic adults without hypertension
C. A resting ECG is reasonable in asymptomatic adults with hypertension
D. All of the above

4.19. Which of the following is a class III indication in the assessment of asymptomatic adults?
A. Measurement of arterial stiffness
B. Obtaining a resting ECG
C. Obtaining an echocardiogram in a patient with hypertension
D. Stress MPI in an individual with diabetes mellitus

4.20. Which of the following is not indicated regarding assessment of an asymptomatic adult with diabetes mellitus
A. Measurement of hemoglobin A1C
B. Stress MPI
C. Testing for microalbuminuria
D. Coronary CT angiogram

4.21. The thallium scan in Figure 4.21 (study 2 is a 4 h redistribution) is from a 47-year-old man presenting with chest pain and ejection fraction (EF) of 35%. The coronary angiogram showed origin occlusion of LAD with collaterals from the right. Rest of the vessels were normal. What would you do?
A. Refer for single-vessel coronary artery bypass grafting with possible left internal mammary artery to left anterior descending (LAD) artery
B. Perform a positron emission tomography scan for viability
C. Refer for implantable cardioverter-defibrillator
D. None of the above

4.22. A 55-year-old man with diabetes and prior myocardial infarction with a right coronary artery (RCA) stent presented with chest pain. His cardiac markers were normal and EF on echo was 45% with inferior wall hypokinesis. The results of a stress Sestamibi scan are shown in Figure 4.22. What would you recommend?
A. Coronary angiography
B. Do stress echo
C. Perform stress perfusion scan in 6 months
D. Medical management only at this point

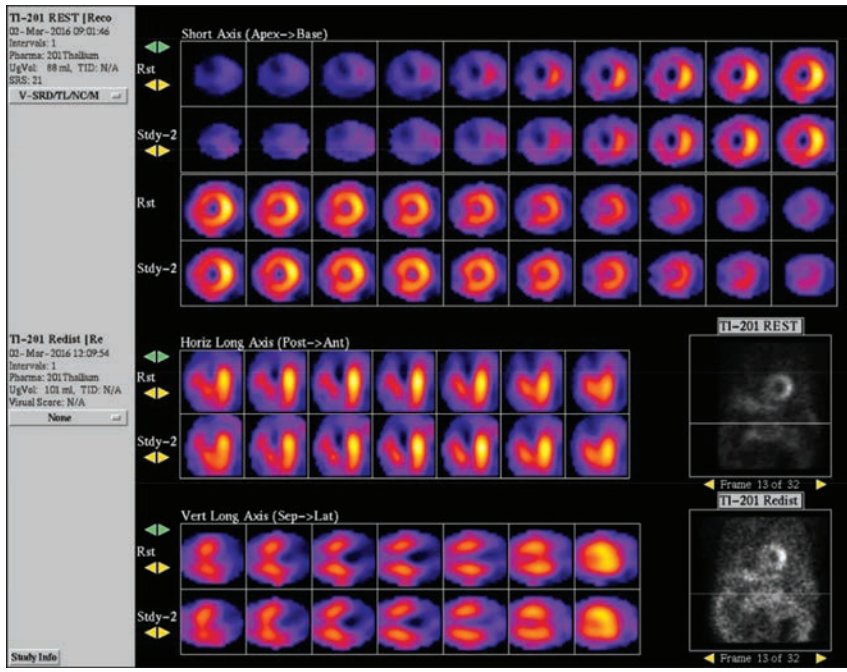

Figure 4.21

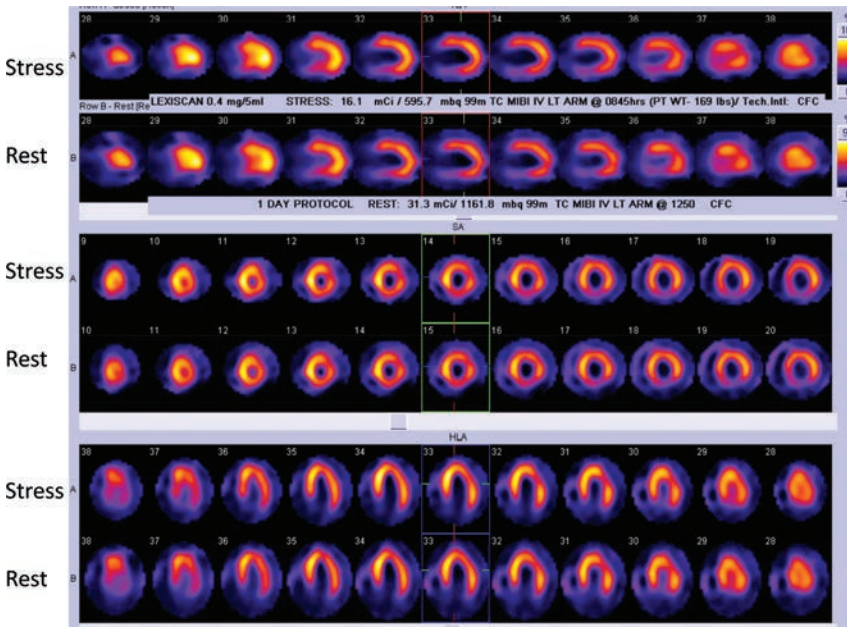

Figure 4.22

4.23. A 67-year-old man with hypertension and diabetes presented with central chest pain lasting 30 min. There were no ECG changes, and cardiac markers were negative. The results of a stress perfusion study are shown in Figure 4.23. What will you recommend?

A. Coronary angiography
B. Medical management only
C. Perform stress echo
D. None of the above

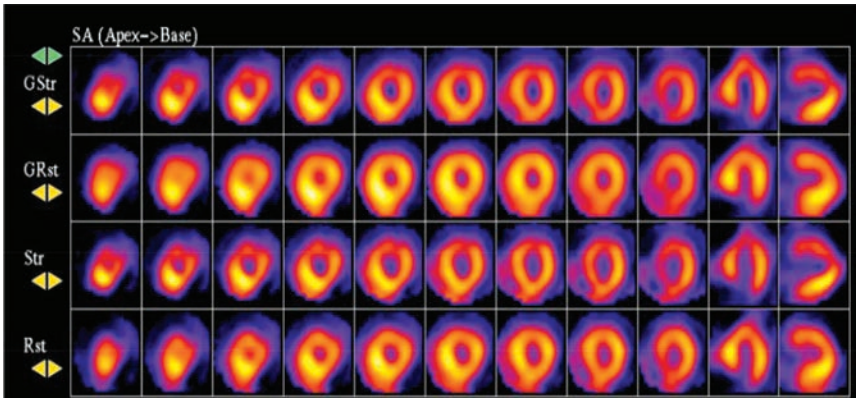

Figure 4.23

4.24. What is the stress perfusion image shown in Figure 4.24 suggestive of?

A. Reversible ischemia of large LAD area
B. Infarct of LAD area
C. Ischemia of RCA area
D. Ischemia of circumflex area

4.25. What does the stress perfusion image in Figure 4.25 show?

A. Reversible apical perfusion defect
B. Reversible defect of entire LAD area
C. Inferior wall ischemia
D. Apical infarct

4.26. What is the stress perfusion scan in Figure 4.26 suggestive of?

A. Perfusion defect in LAD area
B. Ischemia of inferior wall
C. Apical infarct
D. Normal rest and stress perfusion

4.27. The results of stress perfusion only are shown in Figure 4.27 (no rest perfusion shown). What are the results indicative of?

A. Normal stress perfusion and normal left ventricular wall motion
B. Normal perfusion with inferior hypokinesis
C. Anterior perfusion defect with normal wall motion
D. Inferior perfusion defect with inferior hypokinesis

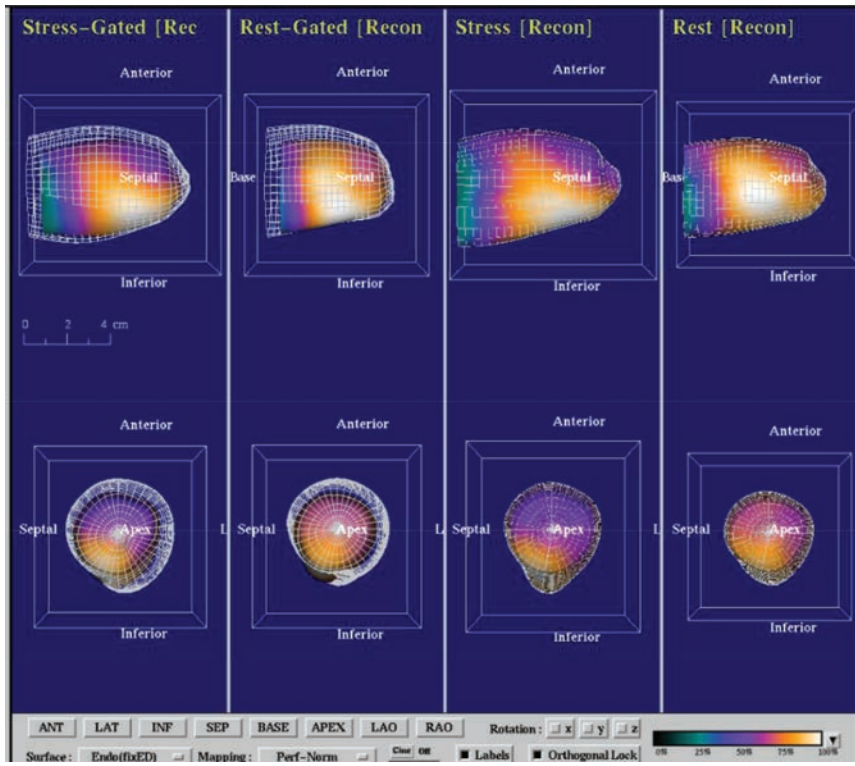

Figure 4.24

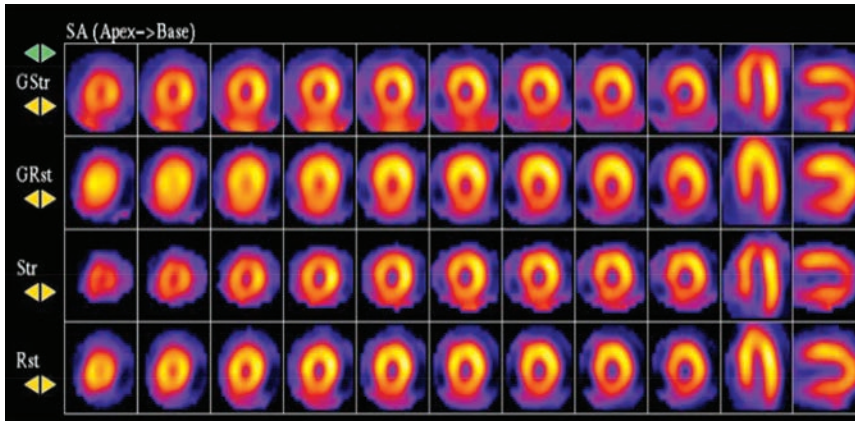

Figure 4.25

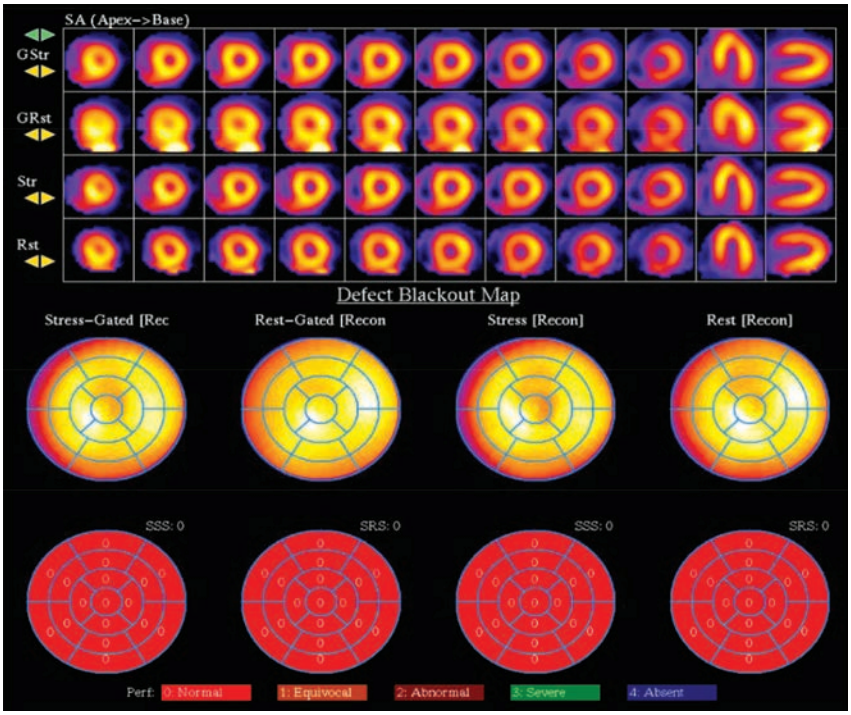

Figure 4.26

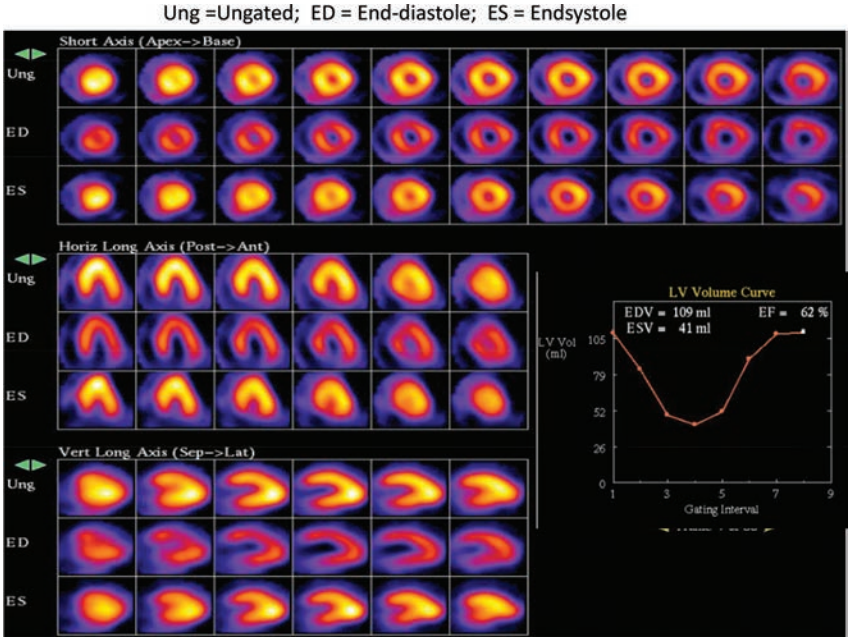

Figure 4.27

4.28. What is the rest/stress perfusion study shown in Figure 4.28 indicative of?

- **A.** Inferior wall infarction
- **B.** Inferior wall ischemia
- **C.** Inferior and anterior ischemia
- **D.** Anterior wall infarct with minor reversibility

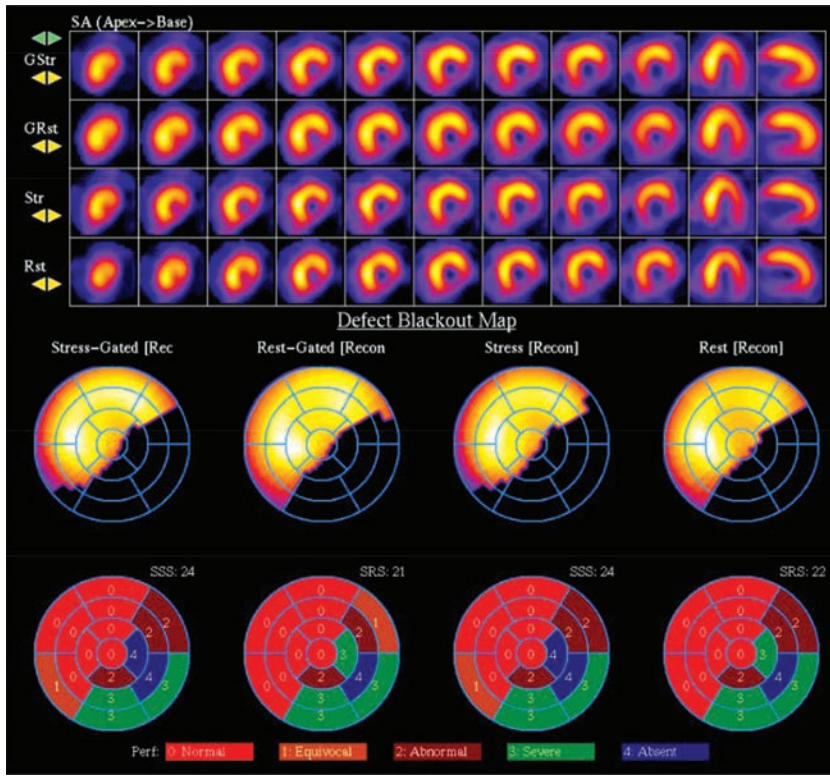

Figure 4.28

4.29. What is the patient whose rest/stress perfusion test results are shown in Figure 4.29 likely to have?

- **A.** Severe LAD artery lesion
- **B.** Left main lesion
- **C.** Circumflex lesion
- **D.** RCA lesion

4.30. A 66-year-old diabetic presented to the ER with chest pain. The resting ECG showed nonspecific ST–T changes, and cardiac markers were negative. The patient was on metformin, aspirin, atorvastatin, and lisinopril, with heart rate of 68 bpm and BP of 123/78 mmHg. Cardiac examination was normal. The patient's nuclear stress test is shown in Figure 4.30. What will be a next logical step?

- **A.** Admit for further observation
- **B.** Refer for coronary angiography
- **C.** Discharge home and continue medical management
- **D.** Perform an echocardiogram

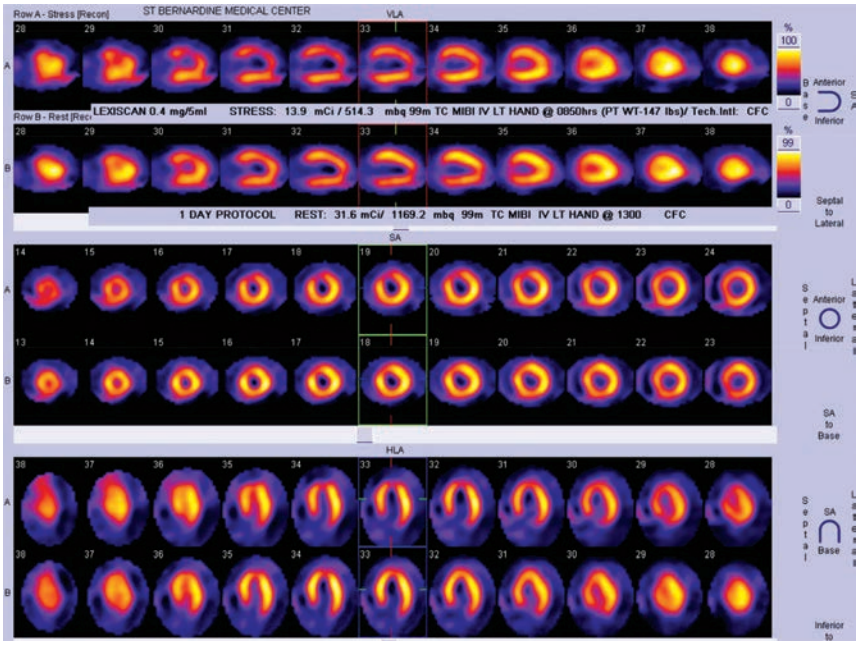

Figure 4.29

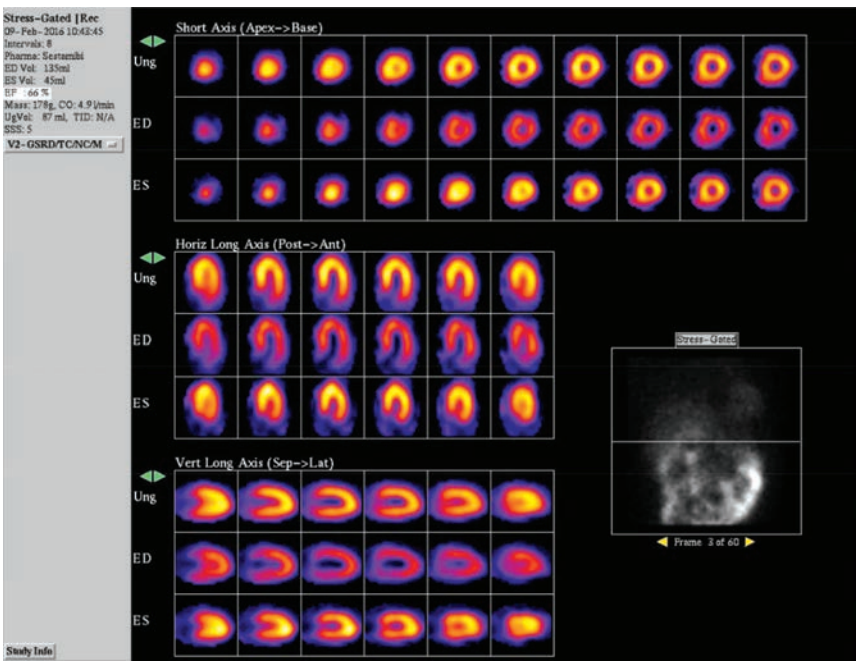

Figure 4.30

4.31. The vasodilator stress study shown in Figure 4.31 is indicative of what?

- **A.** Normal perfusion
- **B.** Ischemia in LAD area
- **C.** Ischemia in RCA area
- **D.** Ischemia in circumflex area

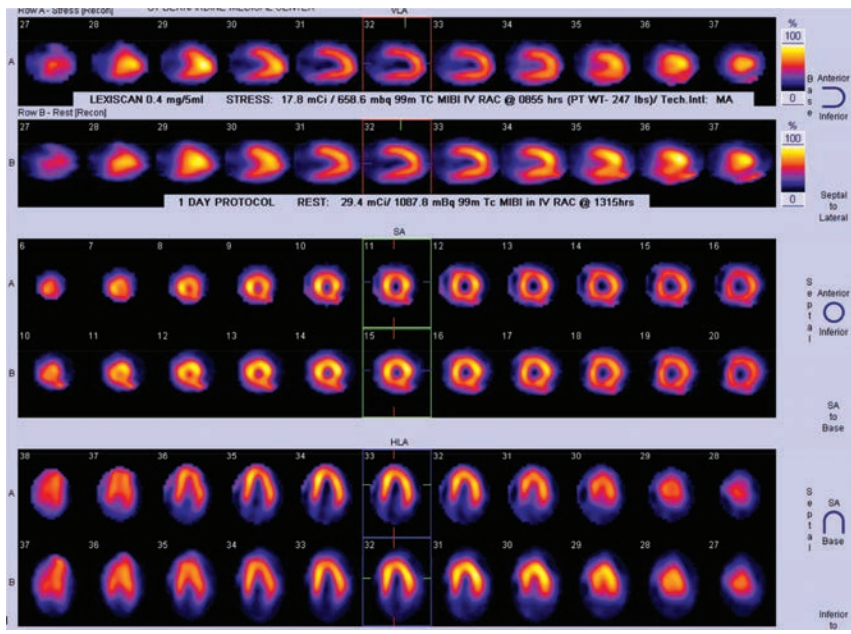

Figure 4.31

Answers

4.1. C. Exercise stress test.

This patient has atypical chest pain. He has risk factors that warrant further testing. His ECG shows no resting abnormalities. If the patient is able to exercise, first step in his evaluation should be exercise stress testing. According to the American College of Cardiology (ACC)/American Heart Association (AHA) 2002 guidelines (Gibbons *et al.*, 2002), if a patient has stable chest pain, has- low to intermediate-risk unstable angina, has symptoms that warrant a diagnosis of coronary artery disease (CAD), is able to exercise, and has an interpretable ECG, then exercise stress testing is the first step.

4.2. C. Coronary angiogram to evaluate for obstructive CAD.

This patient has several high-risk features on his stress test. He walked only 5 min on a Bruce protocol, having to stop due to chest pain. He had significant ST depression at low level of stress that was accompanied by a drop in his systolic BP. These features point to significant CAD. He should be referred for a coronary angiogram.

4.3. D. Exercise myocardial perfusion.

This patient's resting ECG shows preexcitation. According to the ACC/AHA guidelines (Gibbons *et al.*, 2002), class III indications for exercise stress test alone without imaging include preexcitation (Wolff–Parkinson–White) syndrome, electronically paced ventricular rhythm, greater than 1 mm resting ST depression, and complete left bundle branch block.

4.4. C. Stress testing can be undertaken without affecting the predictive value of stress ECG.

With exercise, ST depression usually occurs with RBBB in leads V1–V3. But in leads V4–V6 or the inferior leads, ST changes with stress are similar to those of a normal resting ECG (without RBBB). Hence, the presence of RBBB on resting ECG does not reduce the sensitivity, specificity, or predictive value of the stress ECG in the diagnosis of ischemia.

4.5. D. Order an exercise stress test.

This patient has intermediate probability for CAD based on age, gender, and symptoms. Women have a lower prevalence of obstructive CAD; exercise stress test, which is used to detect focal stenosis, is less sensitive and specific in women. Women tend to have resting ST and T wave changes which can get more pronounced with stress, causing decreased accuracy when used to detect focal disease. Despite the lower accuracy of exercise stress ECG testing, the 2005 ACC/AHA guidelines on the Role of Noninvasive Testing in the Clinical Evaluation of Women Suspected with Coronary Artery Disease recommends exercise ECG as the first test of choice in women with intermediate risk and normal baseline ECG. In women, other parameters, such as poor exercise capacity, low heart rate recovery, and failure to reach target heart rate, are more predictive of outcome than ST changes with stress.

4.6. D. A 44-year-old male with complaints of chest pain brought on by exertion, started a month ago. Physical examination is unremarkable except for an elevated BP of 140/78 mmHg. His ECG shows first-degree atrioventricular block and incomplete RBBB.

The patient in D can safely undergo stress testing. Contraindications to exercise stress ECG testing include severe symptomatic aortic stenosis (scenario A), decompensated heart failure (scenario B), acute pulmonary embolism (scenario C), and within 2 days of an acute myocardial infarction (scenario E).

4.7. E. All of the above.

The scenarios listed are all absolute indications to stop the treadmill test. In addition, ST elevation >1 mm in leads without Q waves, the patient's desire to stop, and technical difficulties in monitoring ECG or BP are all absolute indications to stop the exercise treadmill test.

4.8. B. Preexcitation on the baseline ECG.

It is a class III indication to use an exercise stress test in patients with preexcitation, paced ventricular rhythm, greater than 1 mm resting ST depression, and complete left bundle branch block. It is a class IIa indication to perform an exercise stress test in patients with vasospastic angina and class IIb to perform treadmill stress test in patients with high pretest probability for CAD according to ACC/AHA guidelines (Gibbons *et al.*, 2002).

4.9. B. 14.

Duke treadmill score is calculated as

$$\text{Exercise time (min)} - (5 \times \text{Amount of ST deviation (mm)}) - (4 \times \text{Exercise angina index})$$

(0: none; 1: if exercise angina occurred; 2: if angina was the reason to stop the test). Here, it would be $14 - (5 \times 0) - (4 \times 0) = 14$. Exercise time is based on a standard Bruce protocol.

4.10. D. No further testing.

A Duke treadmill score of >5.5 is suggestive of low risk of death (<1% per year) and hence no further testing is needed. Patients with intermediate score (−10 to +4) have a mortality risk of 1–3% per year and in those with a high risk score (<−10) have a mortality risk of >3% per year.

4.11. B. Obtain global risk score (Framingham).

Obtaining a global risk score in asymptomatic adults without a clinical history of CAD is a class I indication. These scores are helpful in combining individual risk factor measurements into a single quantitative estimate of risk that can be use in prevention strategies. It is not recommended to perform genomic testing or measure lipoprotein or natriuretic peptides in this population; these are considered to be a class III indication (Greenland *et al.*, 2010).

4.12. B. Obtain family history.

Obtaining a family history of atherothrombotic coronary vascular disease is recommended in the assessment of asymptomatic adults (Greenland *et al.*, 2010).

4.13. C. In asymptomatic high-risk adults.

Measurement of CRP is not recommended in asymptomatic high-risk adults (class III). In men 50 years and older or women 60 years and older with an LDL of <130 mg/dL and not on lipid-lowering therapy, hormone replacement therapy, or immunosuppressive therapy, without clinical CAD, diabetes mellitus, chronic kidney disease, severe inflammatory conditions, or contraindications to statin therapy, CRP can be used to select patients for statin therapy (class IIa). It is also deemed reasonable to measure CRP in asymptomatic intermediate-risk men younger than 50 or women younger than 60, for assessment of CAD risk (class IIb) (Greenland *et al.*, 2010).

4.14. D. Resting ECG.

A resting ECG may be reasonable in the assessment of asymptomatic adults with no history of hypertension or diabetes mellitus (class IIb). It is a class III indication to obtain coronary CT angiogram, coronary calcium score, or MRI for plaque detection in low-risk asymptomatic individuals (Greenland *et al.*, 2010).

4.15. A. Stress echocardiogram.

In asymptomatic adults with diabetes mellitus it is reasonable to measure coronary calcium score (class IIa). It is also reasonable to measure hemoglobin A1C and stress MPI (class IIb). Stress MPI may be considered for patients with diabetes or when prior risk assessment suggests high risk, such coronary artery calcium of over 400 (Greenland *et al.*, 2010).

4.16. A. Obtaining global risk score.

It is a class I indication to obtain a global risk score in all asymptomatic women.

4.17. C. In an asymptomatic adult with diabetes mellitus.

Stress MPI may be considered for advanced cardiovascular risk assessment in asymptomatic individuals with diabetes mellitus or in adults with a strong family history of CAD, or when prior risk assessment such as a coronary artery calcium score of over 400. Stress MPI is not recommended for assessment of low- or intermediate-risk asymptomatic individuals (class III) (Greenland *et al.*, 2010).

4.18. B. Echocardiography is recommended in risk assessment of asymptomatic adults without hypertension.

It is a class III indication to perform echocardiography in asymptomatic adults without hypertension. A resting ECG can be obtained in patients with hypertension or diabetes (class IIa) or an echocardiogram obtained in patients with hypertension to detect left ventricular hypertrophy (class IIb) (Greenland *et al.*, 2010).

4.19. A. Measurement of arterial stiffness.

Measurement of arterial stiffness is a class III indication at the present time (Greenland *et al.*, 2010).

4.20. D. Coronary CT angiogram.

It is a class III indication to obtain a coronary CT angiogram in an asymptomatic adult with diabetes (Greenland *et al.*, 2010).

4.21. A. Refer for single-vessel coronary artery bypass grafting with possible left internal mammary artery to left anterior descending (LAD) artery.

Though there is no redistribution, the resting scan shows significant thallium uptake in the anterior wall and septum, indicating viability and revascularization is appropriate. There is good probability that EF will improve, obviating the need for a primary prevention implantable cardioverter-defibrillator.

4.22. D. Medical management only at this point.

There is only a fixed inferior wall defect attributable to an old myocardial infarction. There are no reversible defects.

4.23. A. Coronary angiography.

Note the fully reversible perfusion defect in the anterior wall and septum suggesting proximal LAD artery lesion. The reversible defect is >30% of the myocardium, indicating high risk.

4.24. A. Reversible ischemia of large LAD area.

4.25. A. Reversible apical perfusion defect.

4.26. D. Normal rest and stress perfusion.

4.27. A. Normal stress perfusion and normal left ventricular wall motion.

4.28. A. Inferior wall infarction.

Inferior wall infarction is indicated by the fixed perfusion deficit.

4.29. A. Severe LAD artery lesion.

4.30. C. Discharge home and continue medical management.

The patient has normal perfusion without any ischemia, normal left ventricular wall motion, and normal EF. This indicates a low risk profile.

4.31. B. Ischemia in LAD area.

Echocardiography

5

5.1. Which of the following manipulations will increase the echocardiographic frame rate (see Box 5.1)?
- **A.** Increase depth
- **B.** Increase transmit frequency
- **C.** Decrease sector angle
- **D.** Increase transmit power

5.2. The lateral resolution increases with:
- **A.** Decreasing transducer diameter
- **B.** Reducing power
- **C.** Beam focusing
- **D.** Reducing transmit frequency

5.3. Axial resolution can be improved by which of the following manipulations?
- **A.** Reducing beam diameter
- **B.** Beam focusing
- **C.** Reducing gain
- **D.** Increasing transmit frequency

5.4. Which of the following is associated with continuous-wave Doppler compared with pulsed-wave Doppler?
- **A.** Aliasing
- **B.** Range specificity
- **C.** Ability to record higher velocities
- **D.** All of the above

5.5. An intraoperative transesophageal echocardiogram (TEE) revealed mitral regurgitation (MR) with the following measurements: regurgitant jet area 4 cm^2, proximal isovelocity surface area (PISA) radius 0.8 cm at a Nyquist limit of 50 cm/s at a heart rate of 82 bpm and arterial blood pressure 80/40 mmHg (see Box 5.2). What does this represent?
- **A.** Mild MR
- **B.** Moderate MR
- **C.** Severe MR

5.6. With one exception, for a given regurgitant volume all of the following result in a reduction in the jet size. Which is the exception?
- **A.** Fast heart rate
- **B.** Doubling the sector angle
- **C.** Increasing the imaging depth
- **D.** Increasing the blood pressure

5.7. A patient has an LV outflow tract (LVOT) velocity of 1 m/s, time velocity integral (TVI) of 25 cm, LVOT diameter of 2 cm, aortic transvalvular velocity of 1.5 m/s, and heart rate 70 bpm. What is the cardiac output of this patient?

A. 5.5 L/min
B. 4.5 L/min
C. 6.3 L/min
D. Cannot be determined based on the data given

5.8. A patient with aortic stenosis (AS) has an LVOT diameter of 2 cm, LVOT velocity (V1) of 2.5 m/s, and transaortic valve velocity (V2) of 5 m/s; two-dimensional examination showed moderate systolic anterior motion (SAM) of the mitral leaflet. How would you describe the valvular AS in this patient?

A. Mild
B. Moderate
C. Severe
D. Cannot be calculated based on data given

5.9. In a patient with isolated aortic regurgitation (AR), the following measurements were obtained: transmitral flow 80 cm^3/beat, flow across aortic valve 140 cm^3/beat, TVI of AR signal 100 cm. How would you describe the AR in this patient?

A. Mild
B. Moderate
C. Severe
D. Cannot be determined

5.10. The presence of severe AR in a patient with mitral stenosis (MS) is likely to do which of the following to the calculated mitral valve area by the pressure half-time method?

A. Overestimate the valve area
B. Underestimate the valve area
C. Have no effect

5.11. What is this patient in Figure 5.11 likely to have?

A. Severe AS
B. Severe MR
C. Severe pulmonary hypertension
D. Mild AS

5.12. For the patient in question above, the LVOT diameter was 2 cm and the LVOT velocity by pulse Doppler was 1 m/s. What is the aortic valve area by the continuity equation?

A. 0.2 cm^2
B. 0.3 cm^2
C. 0.5 cm^2
D. 0.8 cm^2

5.13. Figure 5.13 is the continuous wave signal obtained from the pulmonary valve at the mid to proximal esophageal location. What is this patient likely to have?

A. Wide-open pulmonary regurgitation (PR)
B. Mild PR
C. Severe valvular pulmonary stenosis (PS)
D. Severe subvalvular PS

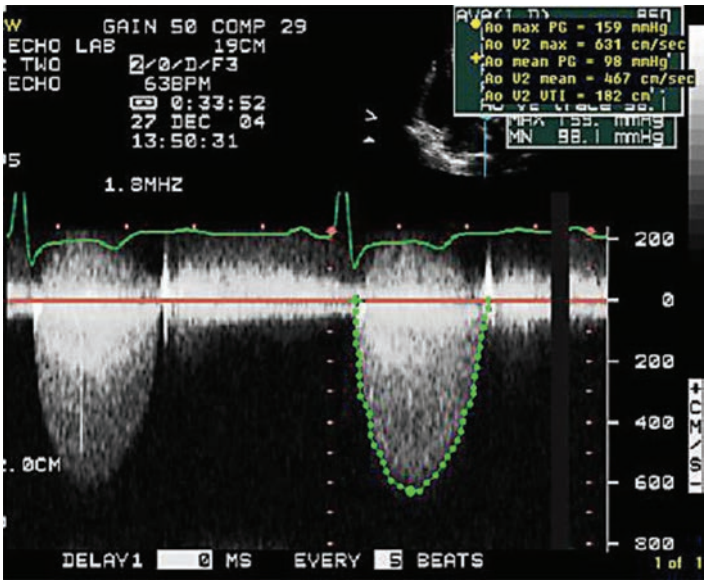

Figure 5.11

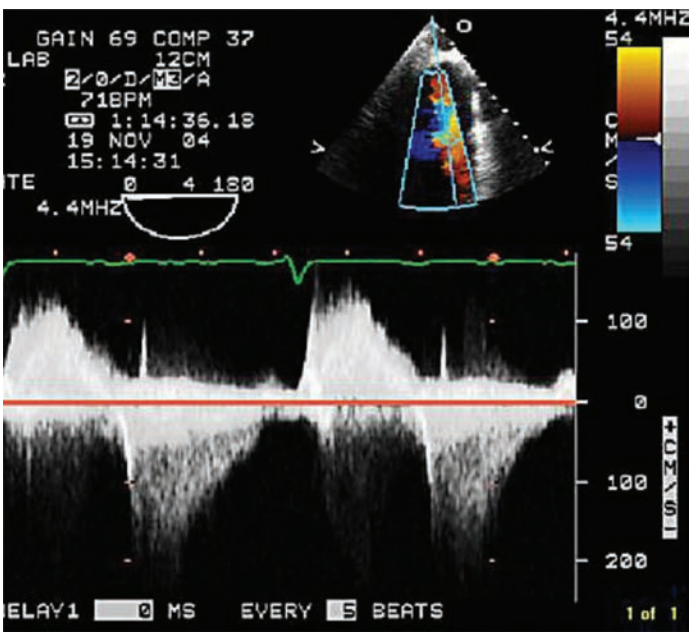

Figure 5.13

5.14. The pulmonary vein flow shown in Figure 5.14 is indicative of what?

A. Elevated LA pressure with normal end diastolic pressure (EDP)
B. Elevated LA pressure with elevated EDP
C. Abnormal LV relaxation with normal EDP
D. Elevated LV EDP with normal LA pressure

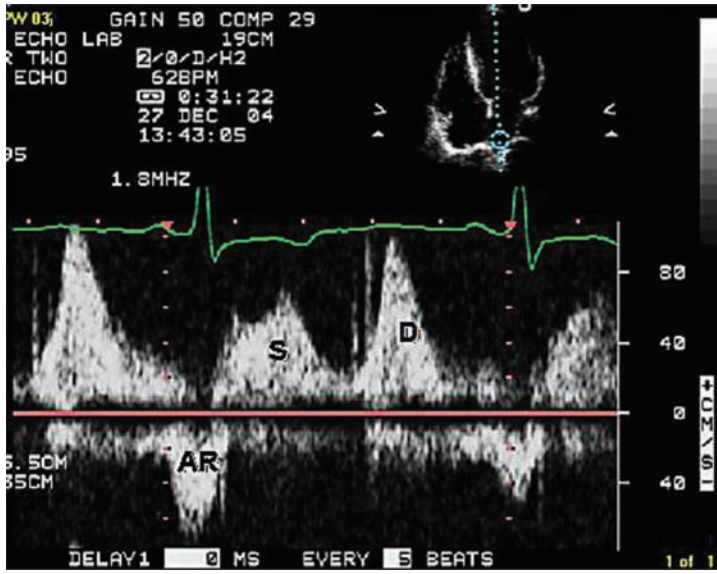

Figure 5.14

5.15. The mitral flow pattern shown in Figure 5.15 is suggestive of what?

A. Normal LA pressure
B. High LA pressure
C. Atrial mechanical failure
D. Abnormal LV relaxation with normal LA pressure

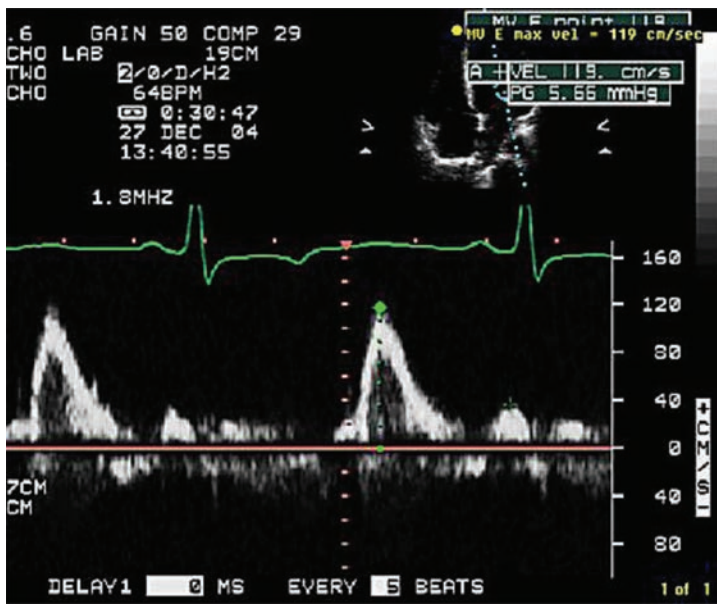

Figure 5.15

5.16. What condition does the patient in Figure 5.16 have?

- **A.** Mitral atresia
- **B.** Tricuspid atresia
- **C.** Transposition of great vessels with atrial baffle
- **D.** Epstein's anomaly

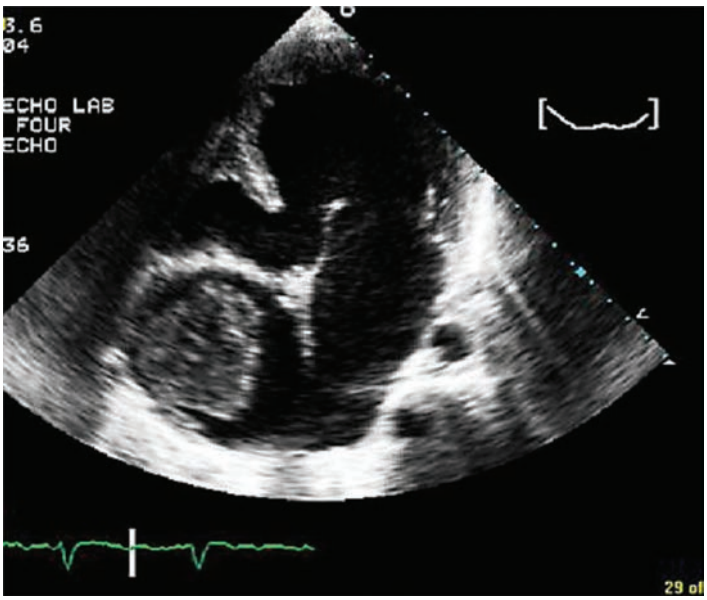

Figure 5.16

5.17. Which of the following does the patient in Figure 5.17 have?

- **A.** Prominent Eustachian valve
- **B.** Ostium secundum ASD
- **C.** Ostium primum ASD
- **D.** Sinus venosus ASD

5.18. What type of flow was recorded from the mid-esophageal position in Figure 5.18?

- **A.** Mitral flow
- **B.** Pulmonary vein flow
- **C.** Superior vena cava flow
- **D.** Flow across ASD

5.19. The patient in Question 5.17 with secundum ASD has ASD dimensions of the defect 3 cm × 2 cm, TVI of flow across the defect is 39 cm, and heart rate of 70/s. What is the approximate shunt flow across the ASD?

- **A.** 12.8 L/min
- **B.** 3 L/min
- **C.** 7 L/min
- **D.** Cannot be calculated

5.20. What is the cause of the patient's mitral valve problem shown in Figure 5.20?

- **A.** Rheumatic heart disease
- **B.** Degenerative valve disease
- **C.** Fen–phen valvulopathy
- **D.** Ischemic heart disease

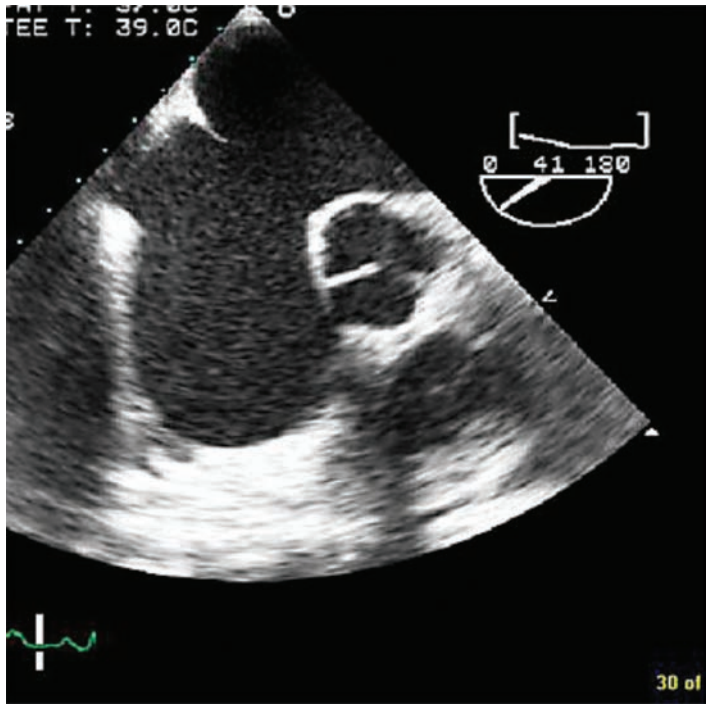

Figure 5.17

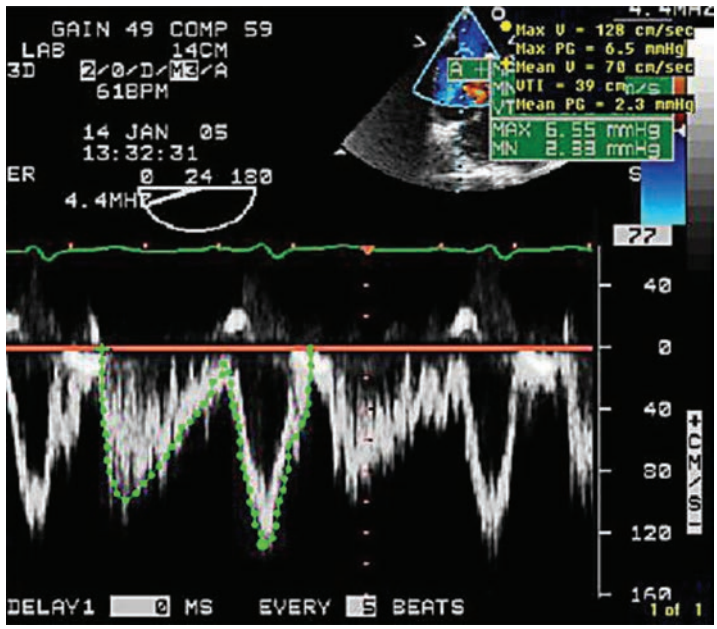

Figure 5.18

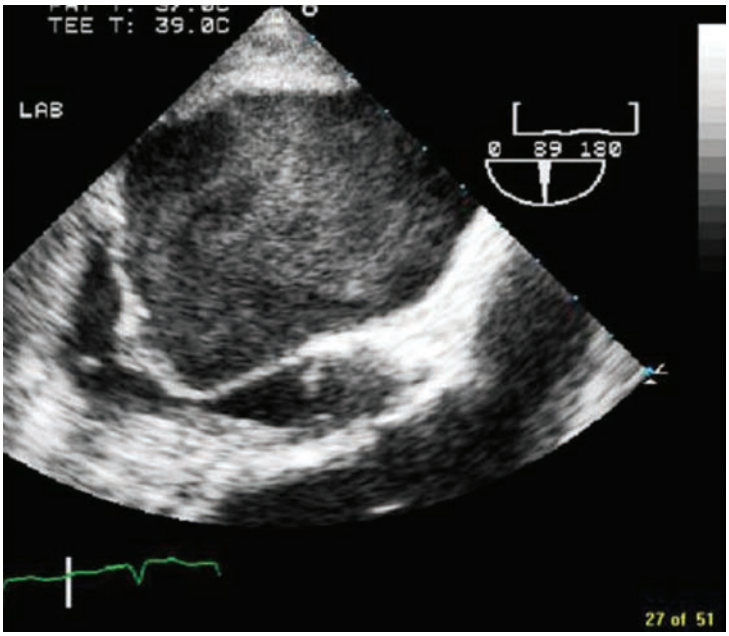

Figure 5.20

5.21. Figure 5.21 shows a patient that may have all of the following except what?
- **A.** Atrial septal defect
- **B.** Wolf–Parkinson–White syndrome
- **C.** TR
- **D.** Bicuspid aortic valve

5.22. The M-mode echocardiogram in Figure 5.22 is suggestive of what?
- **A.** Normal mitral valve motion
- **B.** MS
- **C.** Severe AR
- **D.** High LA pressure

5.23. What is the image shown in Figure 5.23 suggestive of?
- **A.** Mitral annuloplasty
- **B.** Catheter in the coronary artery
- **C.** Biventricular pacemaker or implantable cardioverter-defibrillator (ICD)
- **D.** An artifact

5.24. What is the structure denoted by the arrow in Figure 5.24?
- **A.** LA appendage
- **B.** Left lower pulmonary vein
- **C.** Left upper pulmonary vein
- **D.** Right lower pulmonary vein

5.25. The patient shown in Figure 5.25 has what condition?
- **A.** Valvular AS
- **B.** Subvalvular AS
- **C.** Endocarditis
- **D.** Hypertrophic obstructive cardiomyopathy (HOCM)

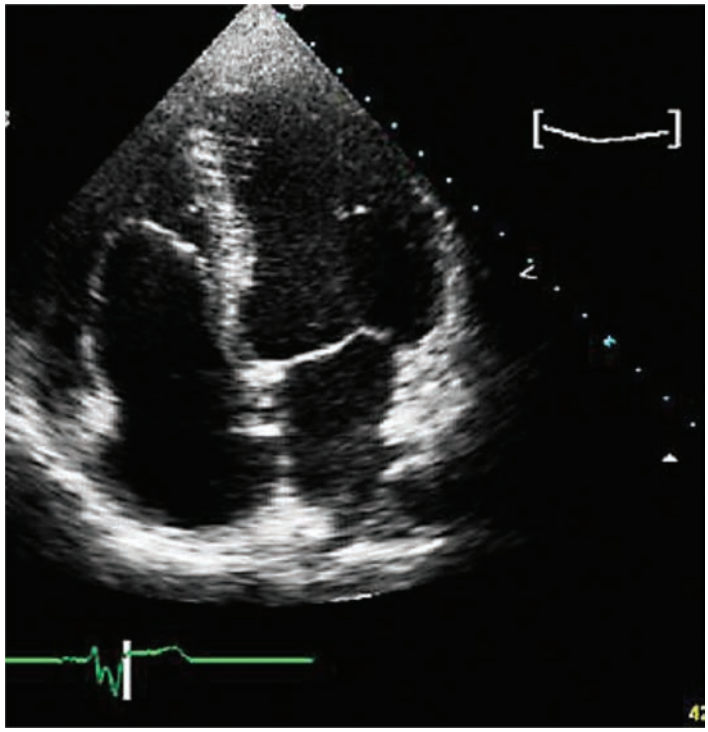

Figure 5.21

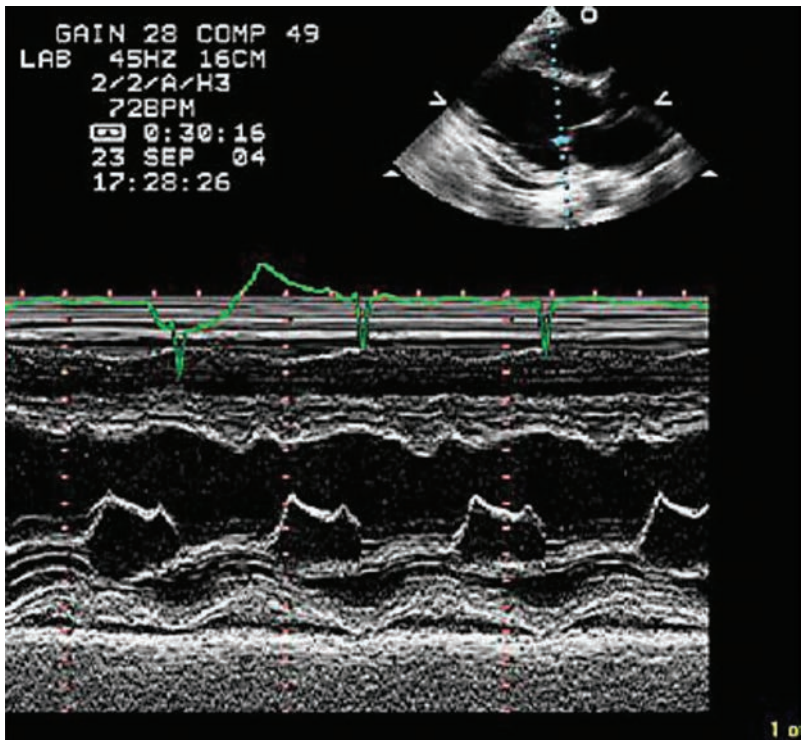

Figure 5.22

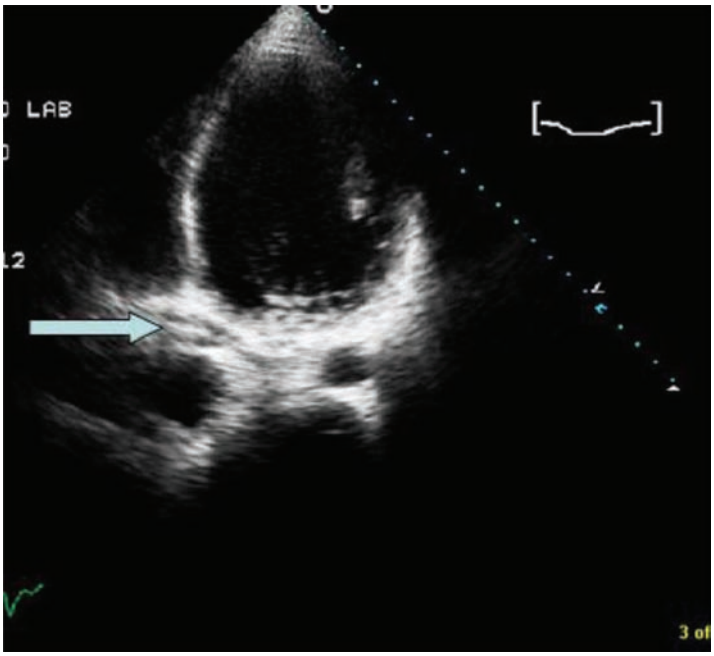

Figure 5.23

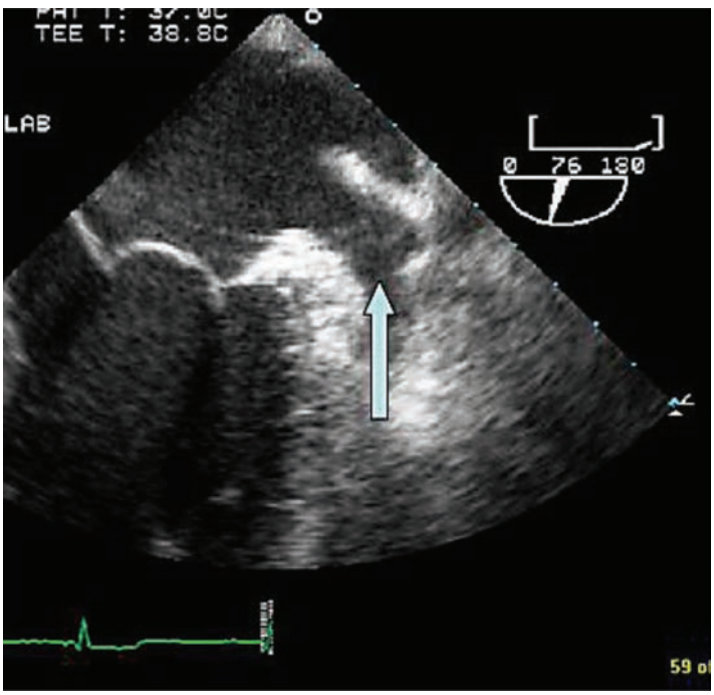

Figure 5.24

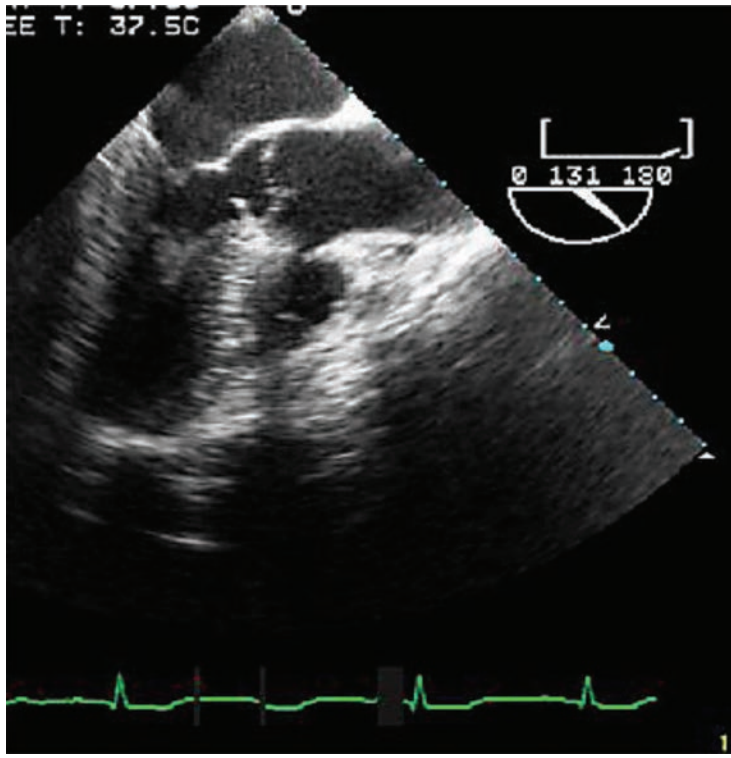

Figure 5.25

5.26. The cause of dyspnea in the patient in Figure 5.26 is likely to be due to what?

- **A.** Left heart failure
- **B.** Primary pulmonary hypertension
- **C.** Chronic obstructive pulmonary disorder
- **D.** None of the above

5.27. Figure 5.27 shows an end systolic frame in a patient with shortness of breath. What is the most likely diagnosis?

- **A.** Ebstein's anomaly
- **B.** Hypertrophic cardiomyopathy
- **C.** ASD
- **D.** Dilated cardiomyopathy

5.28. What is the most likely mechanism of MR in the patient in Figure 5.28?

- **A.** P2 tethering
- **B.** P2 prolapse
- **C.** Bileaflet mitral valve prolapse
- **D.** None of the above

5.29. A 19-year-old patient was stabbed in the precordial area. Examination revealed a loud systolic murmur (Figure 5.29). What is the most likely cause of this murmur?

- **A.** Penetrating injury to the interventricular septum
- **B.** Mitral valve prolapse
- **C.** HOCM
- **D.** None of the above

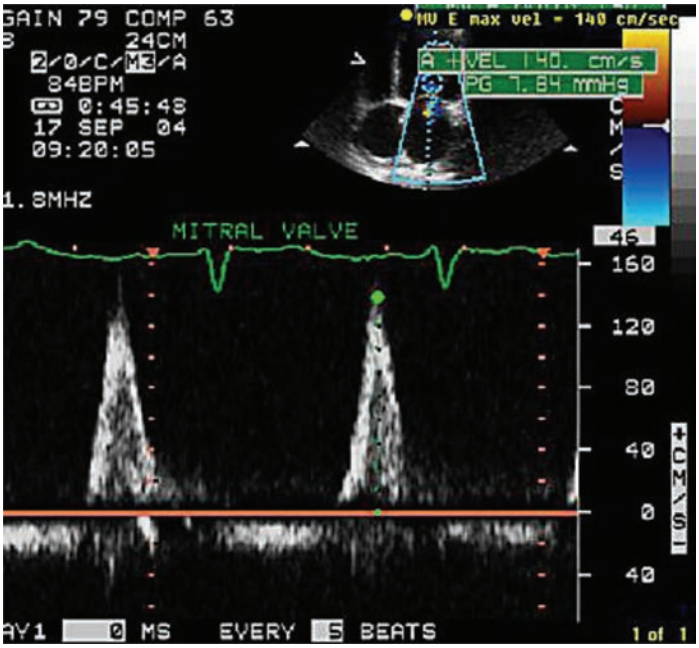

Figure 5.26

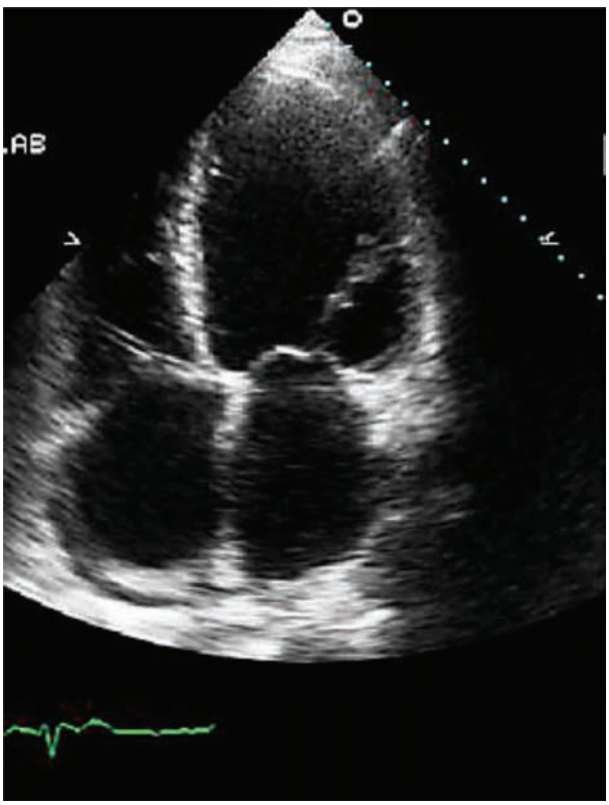

Figure 5.27

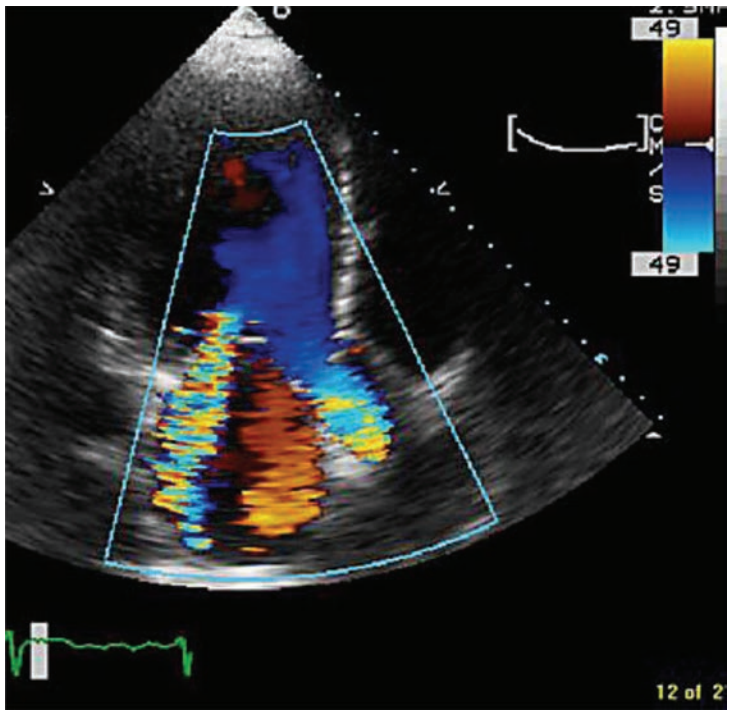

Figure 5.28

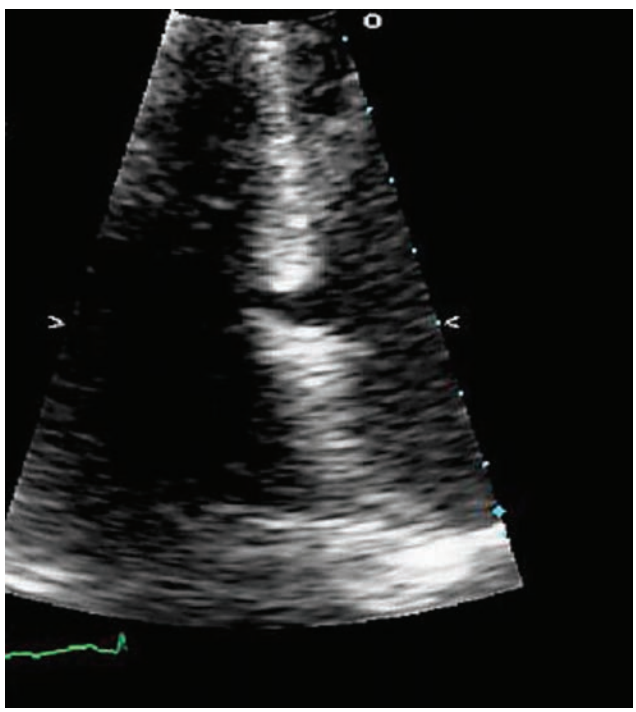

Figure 5.29

5.30. What is the continuous-wave Doppler signal in Figure 5.30 suggestive of?

A. AS and AR
B. MS and MR
C. VSD flow
D. Aortic flow in a patient with coarctation

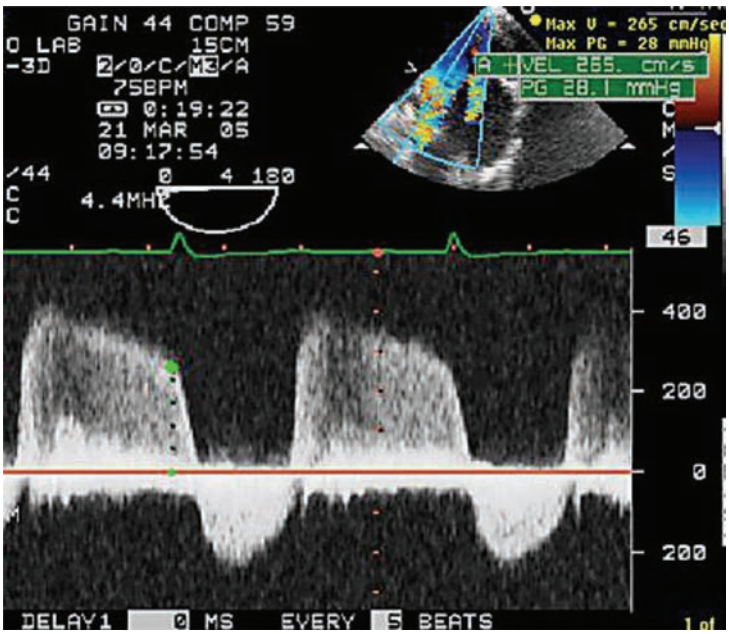

Figure 5.30

5.31. The continuous wave signal in Figure 5.31 was obtained from the mid-transesophageal location. What is it indicative of?

A. AS and AR
B. MS and MR
C. VSD flow
D. None of the above

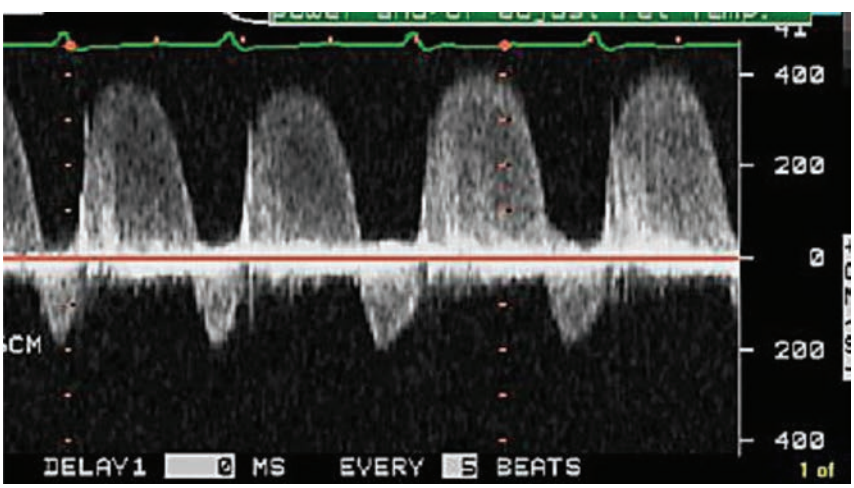

Figure 5.31

5.32. Figure 5.32 shows a TEE image from the mid-esophagus of a late diastolic frame of the aortic valve. What is this patient most likely to have?

A. Severe AR
B. Severe AS
C. HOCM
D. Ascending aortic dissection

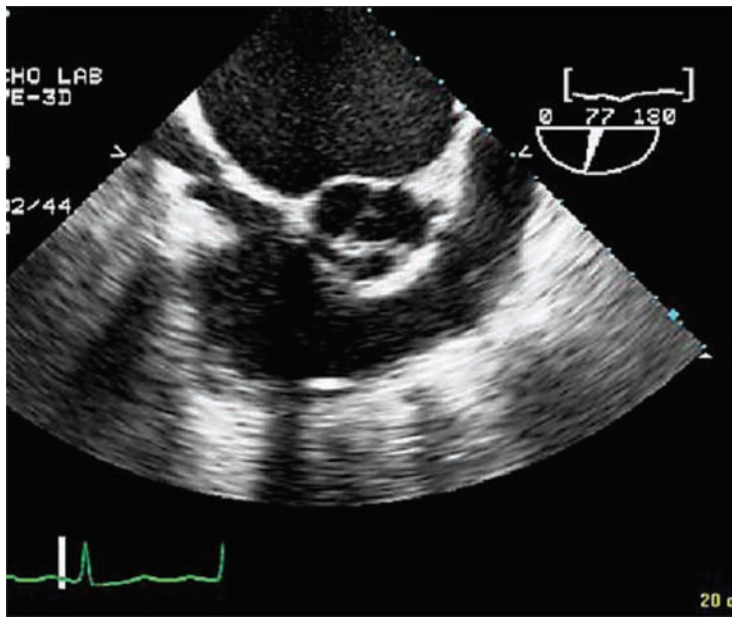

Figure 5.32

5.33. What is the patient in Figure 5.33 most likely to have?

A. Acute severe MR
B. Chronic severe MR
C. Severe MS and mild MR
D. None of the above

5.34. The patient in Figure 5.34 had *Staphylococcus aureus* endocarditis of the aortic valve. What is the most likely cause?

A. Central venous catheter-associated infection
B. Dental work
C. Immunosuppressed state
D. Intravenous drug use

5.35. What is the image of the aortic valve in Figure 5.35 suggestive of?

A. Aortic valve vegetation
B. Node of Arantius
C. Lambl's excrescences
D. Ascending aortic dissection causing prolapse of the noncoronary cusp

5.36. What is the most likely cause of the signal shown in Figure 5.36?

A. HOCM
B. Critical valvular AS
C. Acute MR
D. None of the above

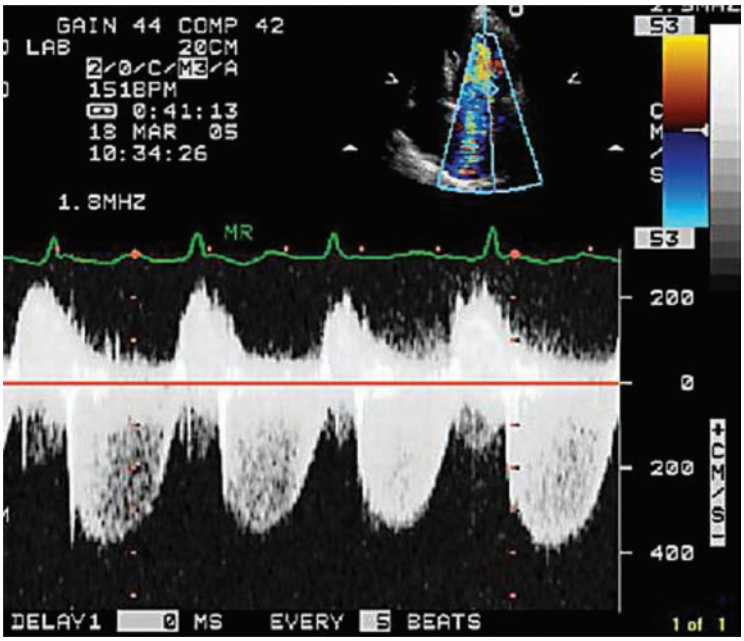

Figure 5.33

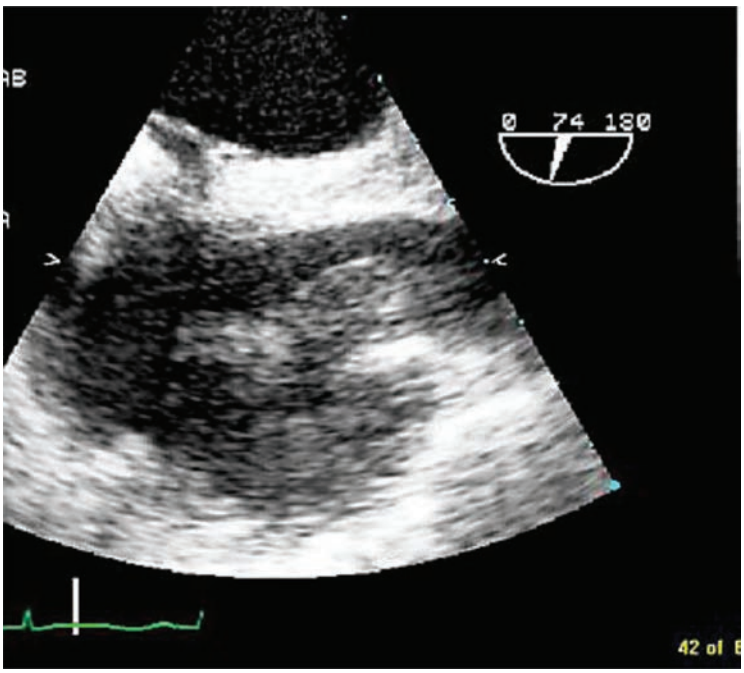

Figure 5.34

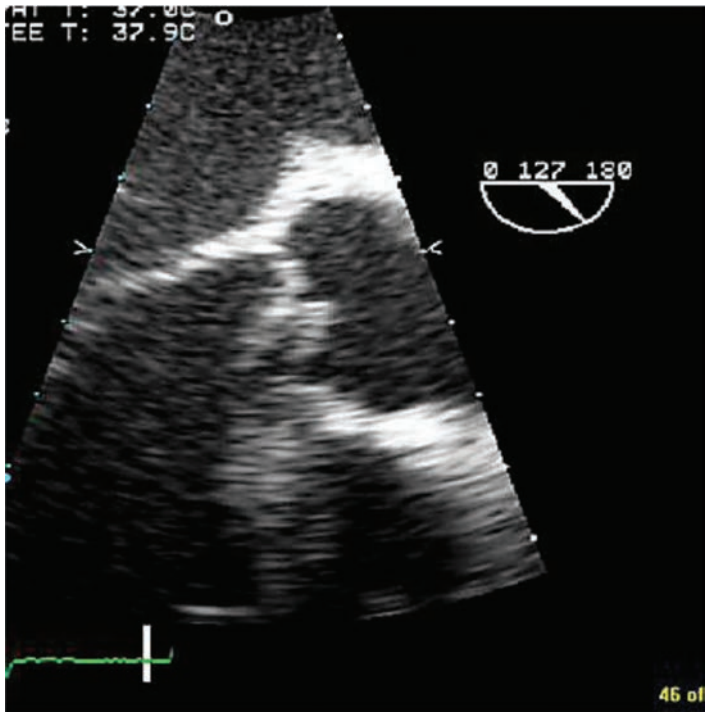

Figure 5.35

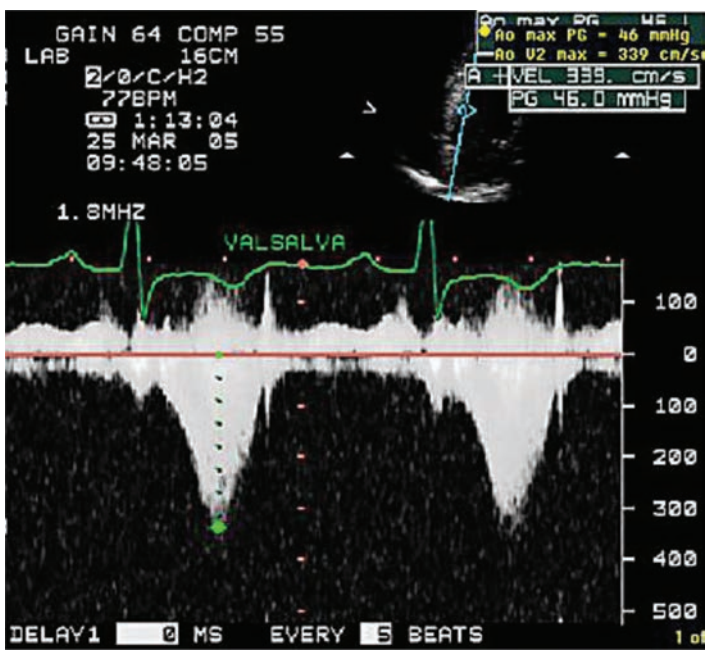

Figure 5.36

5.37. What is the image shown in Figure 5.37 suggestive of?

A. Bioprosthetic tricuspid valve
B. Carcinoid valvulopathy of tricuspid valve
C. Tricuspid annuloplasty ring
D. Large tricuspid vegetation

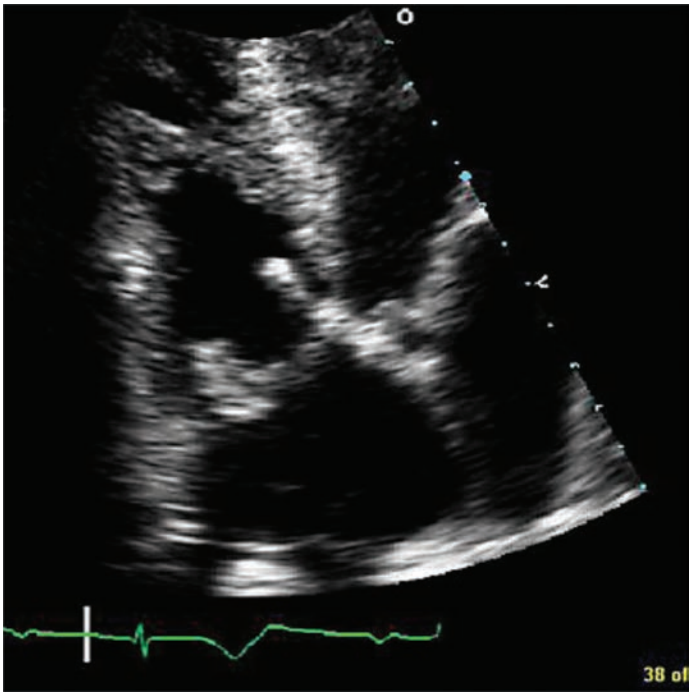

Figure 5.37

5.38. What is the 65-year-old patient with MR in Figure 5.38 likely to have?

A. An opening snap
B. Third heart sound
C. Fourth heart sound
D. Summation gallop

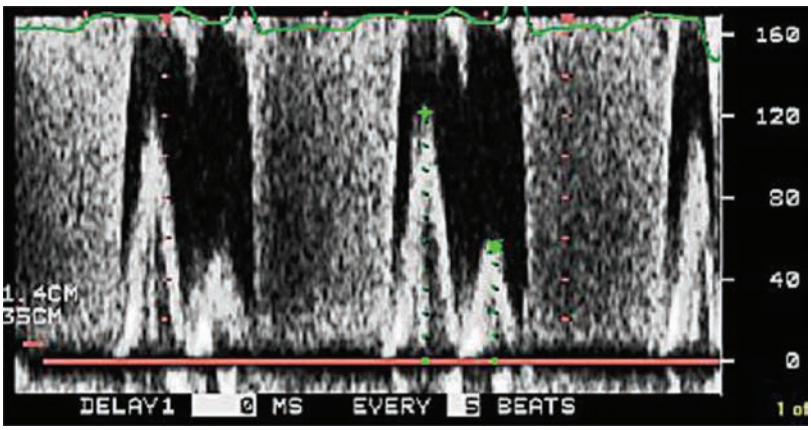

Figure 5.38

5.39. What is the continuous-wave Doppler signal in Figure 5.39 consistent with?

A. Critical AS
B. Severe MR
C. Maladie de Roger
D. None of the above

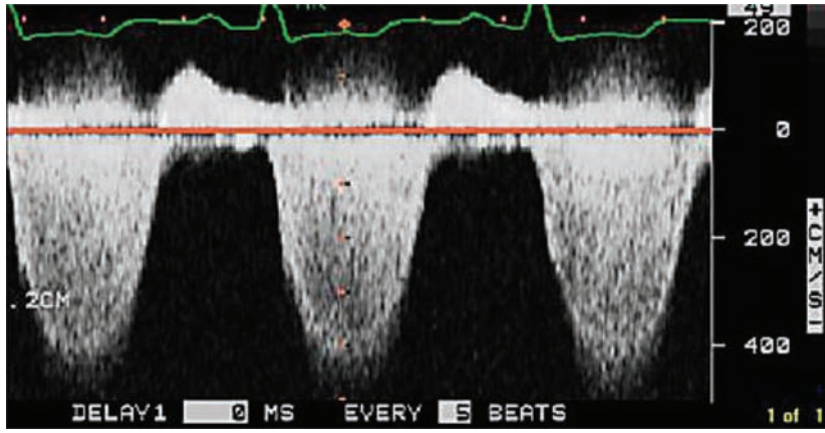

Figure 5.39

5.40. The TR signal in Figure 5.40 was obtained from TEE. The clinically estimated right atrial (RA) pressure in this patient was 20 mmHg and there is no PS. What would the PA systolic pressure in this patient be?

A. 30 mmHg
B. 50 mmHg
C. 80 mmHg
D. Cannot be calculated

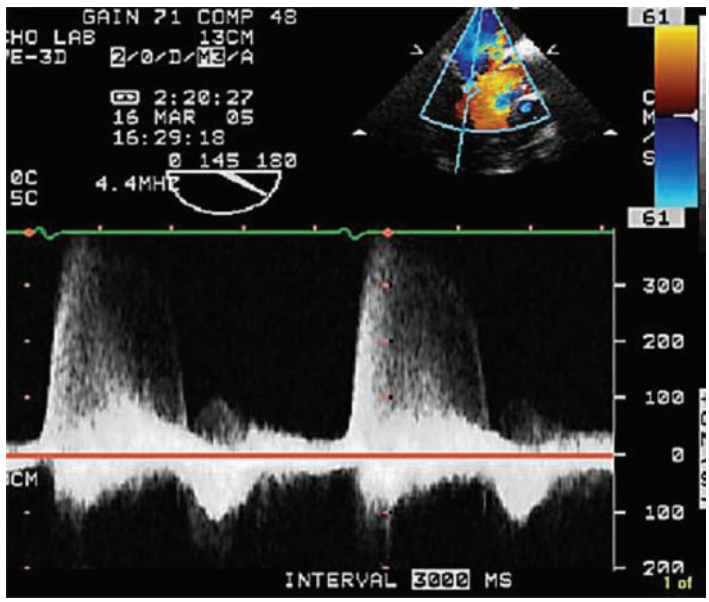

Figure 5.40

5.41. What condition is the patient in Figure 5.41 likely to have?

A. Acute severe AR
B. Mild AR
C. MS
D. None of the above

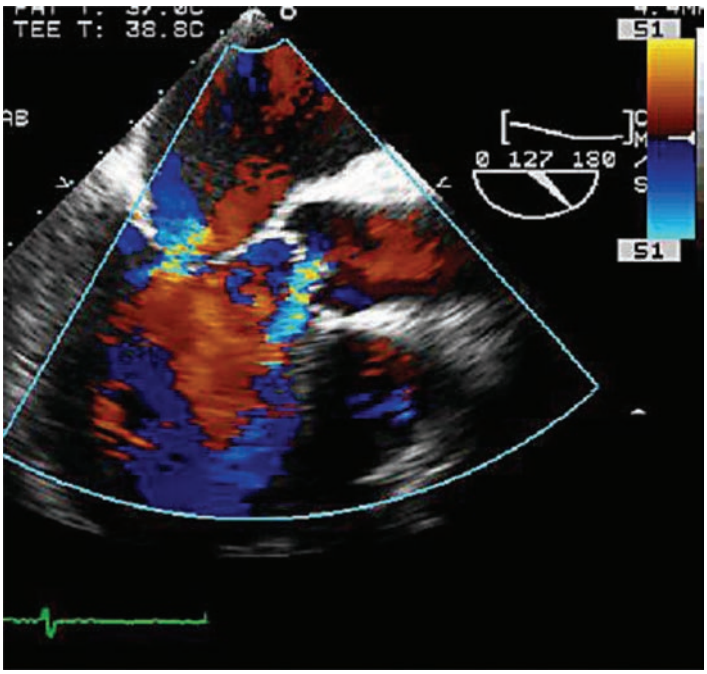

Figure 5.41

5.42. The transmitral flow in Figure 5.42 is obtained from the esophageal transducer location from a patient with *Staphylococcus aureus* bacteremia and acute hemodynamic decompensation. The patient is in sinus rhythm. What is the most likely cause of his decompensation?

A. Acute MR
B. Acute AR
C. Rupture of the ventricular septum
D. None of the above

5.43. The pulse-wave Doppler flow signal in the descending thoracic aorta on a TEE shown in Figure 5.43 is indicative of what?

A. Coarctation of the aorta
B. Middle aortic syndrome
C. Severe AR
D. HOCM

5.44. What is the likely cause of heart failure in the 30-year-old man shown in Figure 5.44?

A. Noncompaction of the left ventricle
B. Hemochromatosis
C. Cardiac amyloid
D. Hypertrophic cardiomyopathy

5.45. What is the structure indicated by the arrow in Figure 5.45?

A. IVC–RA junction
B. Superior vena cava
C. Anomalously draining right upper pulmonary vein
D. ASD

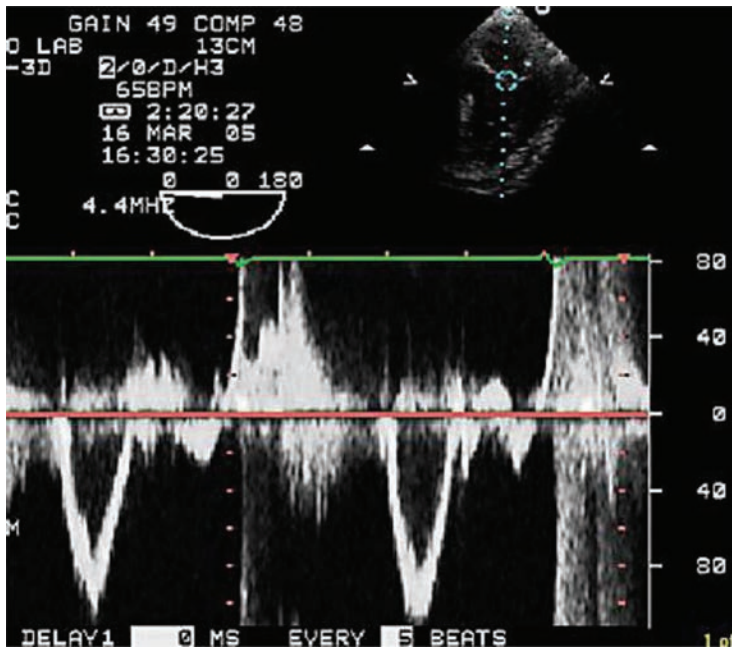

Figure 5.42

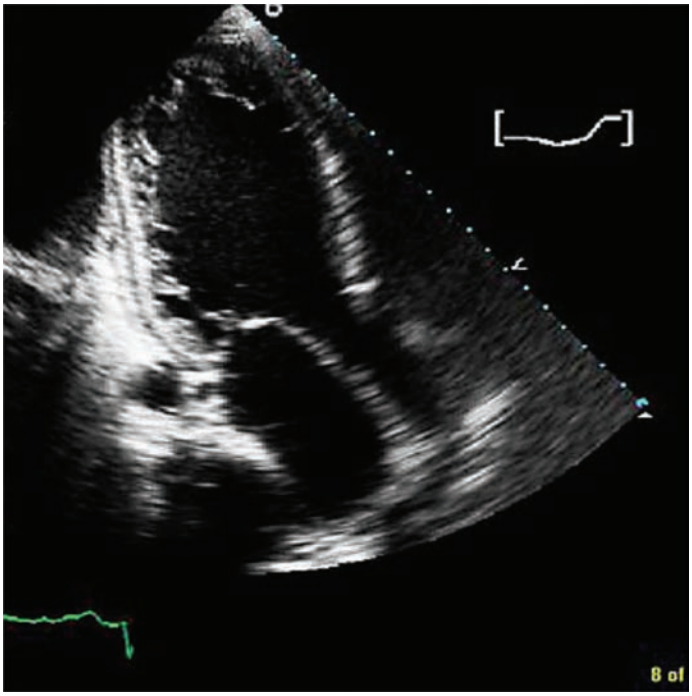

Figure 5.44

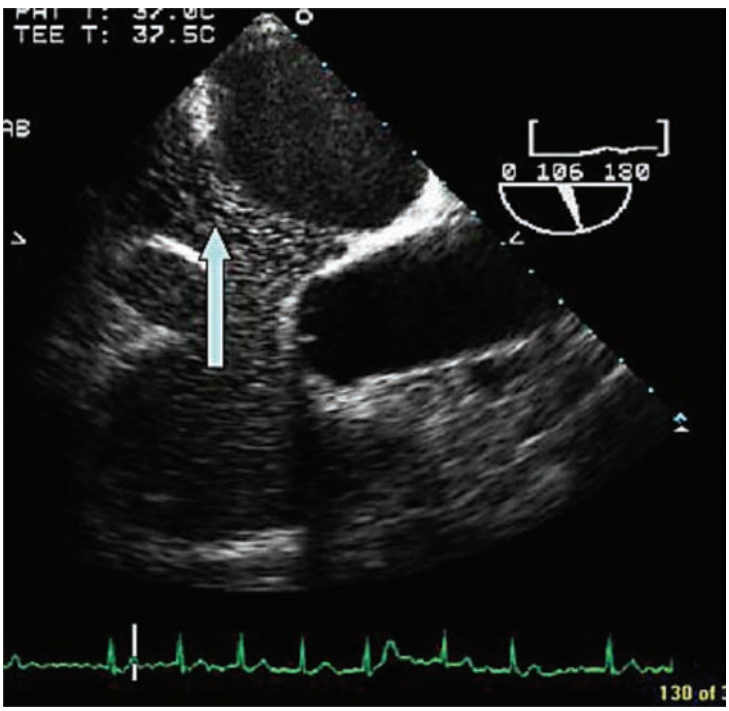

Figure 5.45

5.46. What is the approximate MR flow rate of the patient in Figure 5.46 (PISA radius of 0.9 cm, aliasing velocity of 38 cm/s)?

A. ~200 cm^3/s
B. ~200 cm^3/min
C. ~100 cm^3/min
D. ~100 cm^3/s

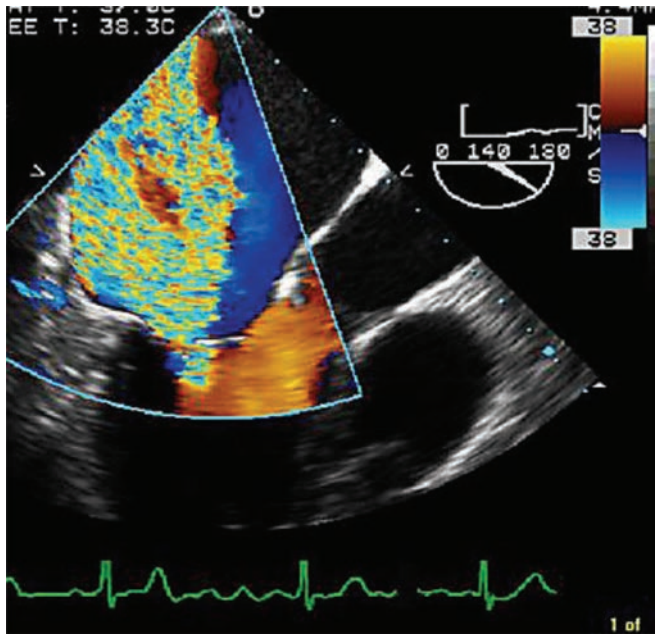

Figure 5.46

5.47. What is the likely diagnosis of the patient in Figure 5.47?

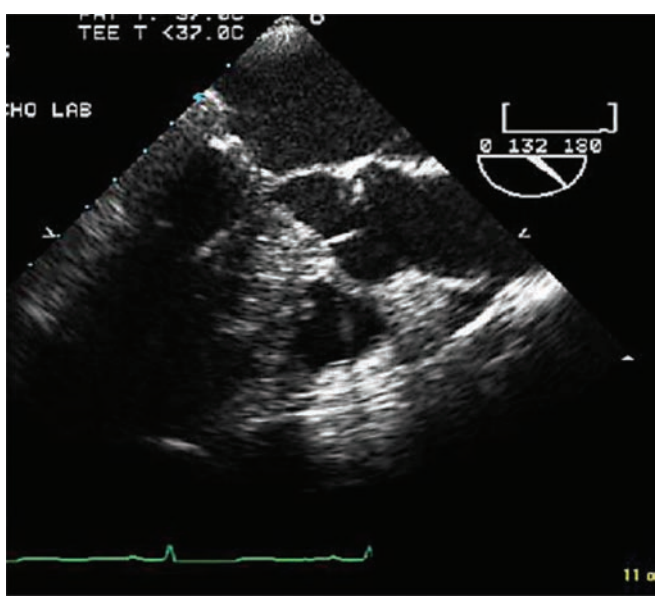

Figure 5.47

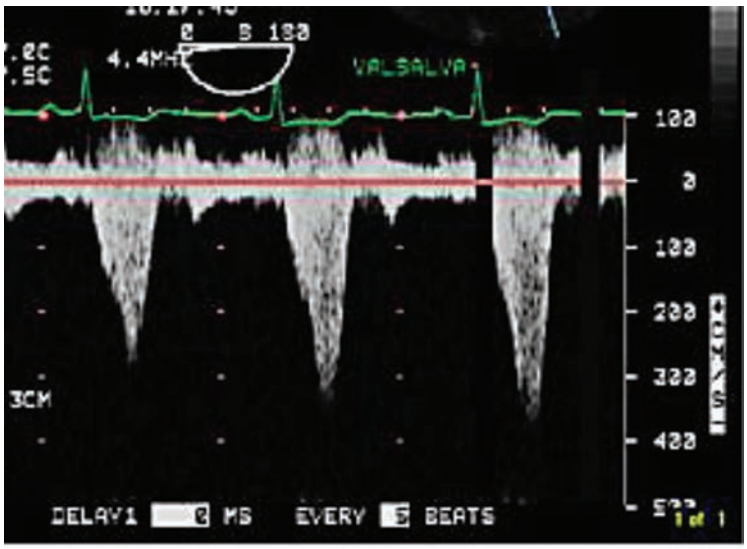
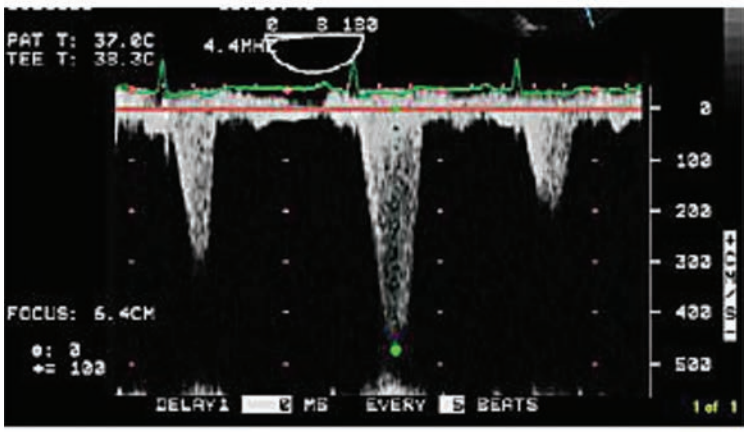
A. An early diastolic murmur
B. Late-peaking systolic ejection murmur with absent A2 component of S2
C. Late-peaking systolic murmur increased by Valsalva's maneuver and normal A2
D. Mid-diastolic murmur

5.48. What is the most likely diagnosis of the patient in Figure 5.48?

A. HOCM
B. Severe AS
C. Mitral valve prolapse
D. None of the above



At rest



With Valsalva

Figure 5.48

5.49. What is the most likely diagnosis of the patient in Figure 5.49?

- **A.** Apical HOCM
- **B.** Hypertensive heart disease
- **C.** Endomyocardial fibrosis
- **D.** None of the above

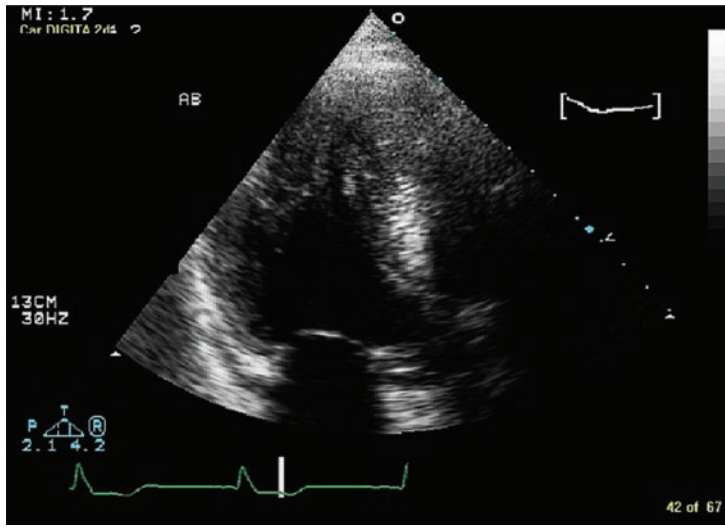


Figure 5.49

5.50. The appearance of the atrial septum in the patient in Figure 5.50 is due to what?

- **A.** ASD repair with a pericardial patch
- **B.** ASD closure device
- **C.** PFO closure device
- **D.** None of the above

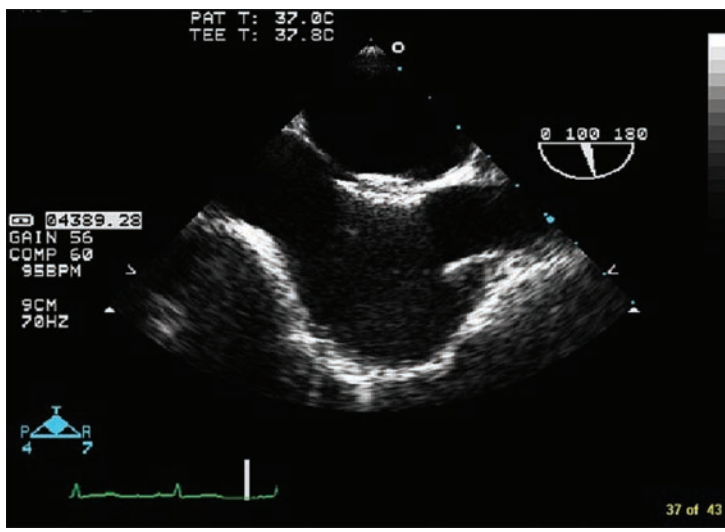

Figure 5.50

5.51. What does Figure 5.51 show?

A. Normal native tricuspid valve
B. Normal bioprosthetic valve
C. Vegetation on a bioprosthetic valve
D. Avulsion of the tricuspid valve

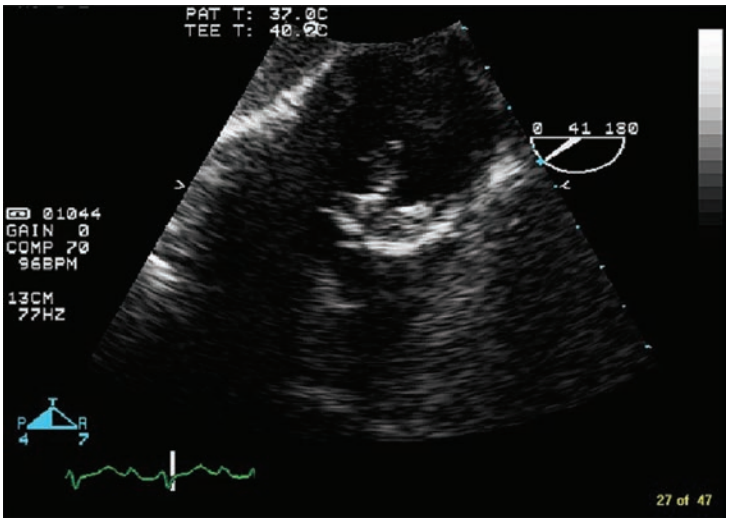

Figure 5.51

5.52. A 31-year-old woman with no other medical history had two episodes of transient ischemic cerebral attacks, the first one after a long duration of air travel and the second one during straining in the rest-room. From the TEE image in Figure 5.52, what is the most likely cause of this patient's attacks?

A. Paradoxical embolism
B. Vagally mediated atrial fibrillation
C. LA thrombus
D. None of the above

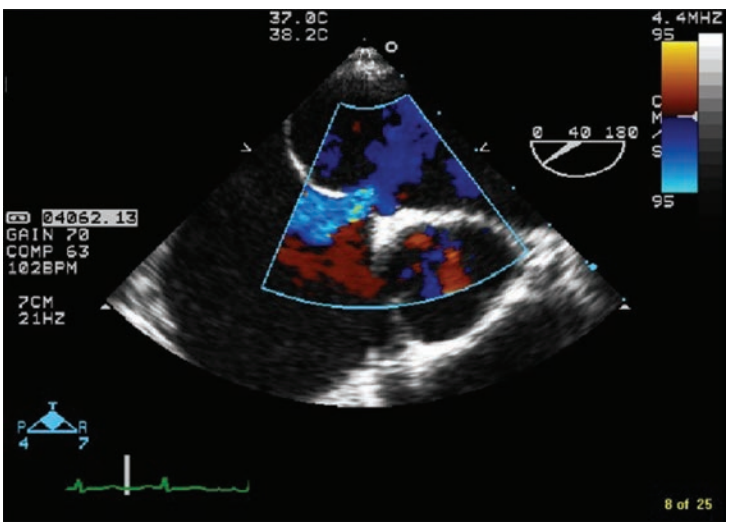

Figure 5.52

5.53. A 35-year-old patient with AIDS and bicuspid aortic valve has *Staphylococcus* bacteremia. What is the parasternal long-axis color flow image in Figure 5.53 suggestive of?

A. Right coronary artery flow
B. Pulmonary vegetation
C. Fistulous communication between aorta and right ventricle
D. None of the above

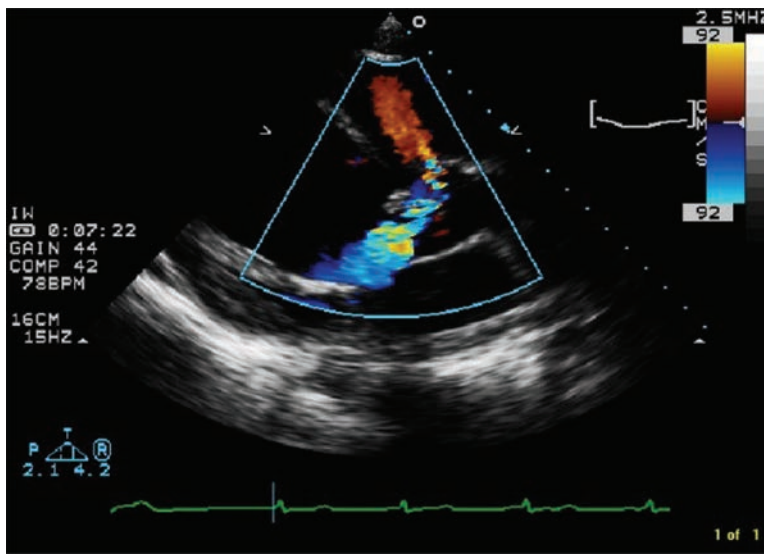

Figure 5.53

5.54. What are the patient's bilateral *Staphylococcus* lung abscesses shown in Figure 5.54 likely due to?

A. Tricuspid valve endocarditis
B. Pulmonary valve endocarditis
C. Catheter-related infection of superior vena cava and right atrium
D. None of the above

5.55. What is the structure indicated by the arrow in Figure 5.55?

A. Coronary sinus
B. IVC
C. ASD
D. None of the above

5.56. Describe the amount of TR in the patient in Figure 5.56.

A. Mild
B. Moderate
C. Severe
D. Cannot quantify

5.57. Which of the following is the patient in Question 5.56 likely to have?

A. Normal PA pressure
B. Mild pulmonary hypertension
C. Moderate or severe pulmonary hypertension

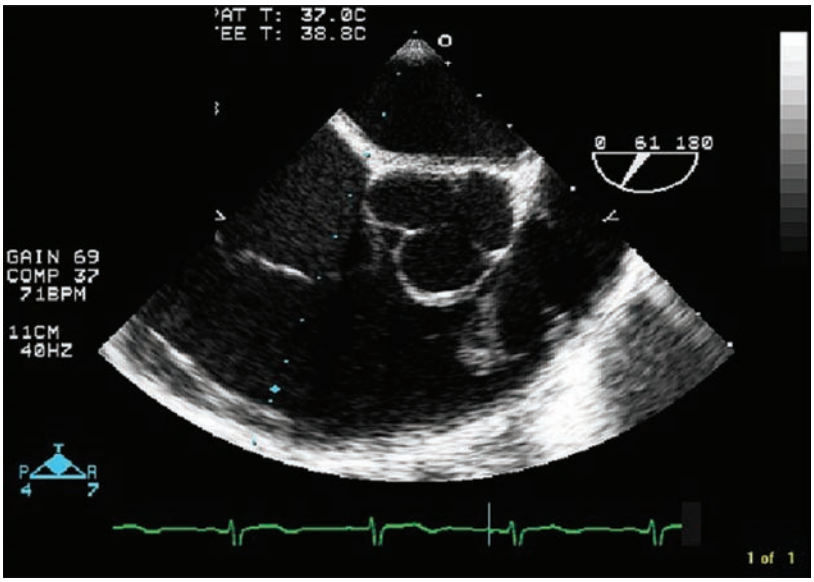

Figure 5.54

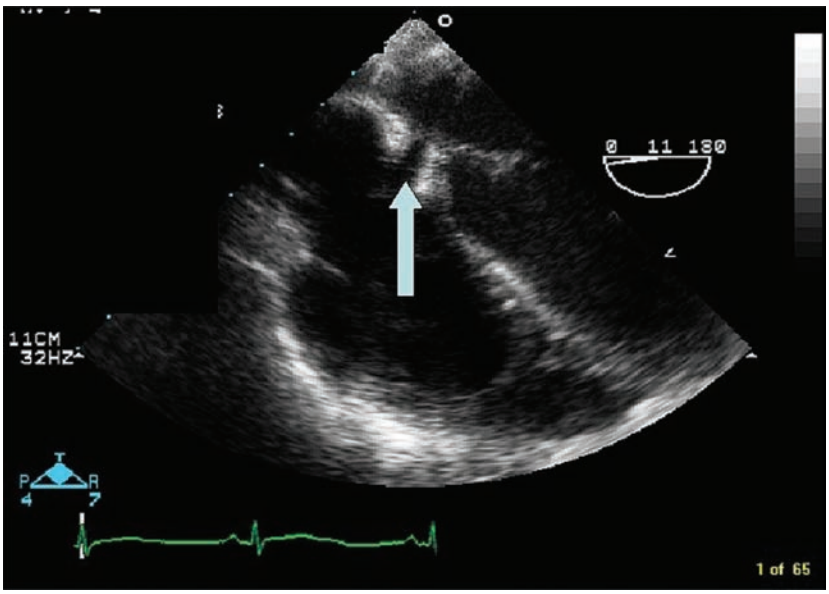

Figure 5.55

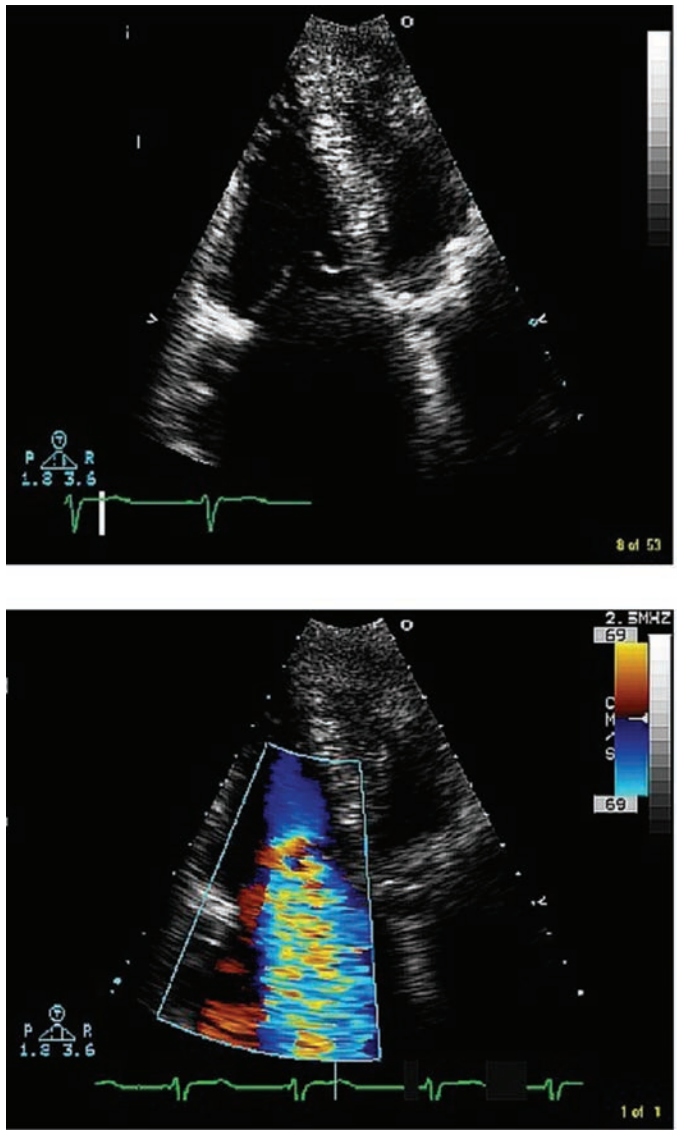

Figure 5.56

5.58. What is the likely type of surgical procedure performed on the mitral valve of the patient in Figure 5.58?

- **A.** Mitral annuloplasty
- **B.** Alfieri procedure
- **C.** Replacement with a bioprosthetic valve
- **D.** Replacement with a mechanical valve

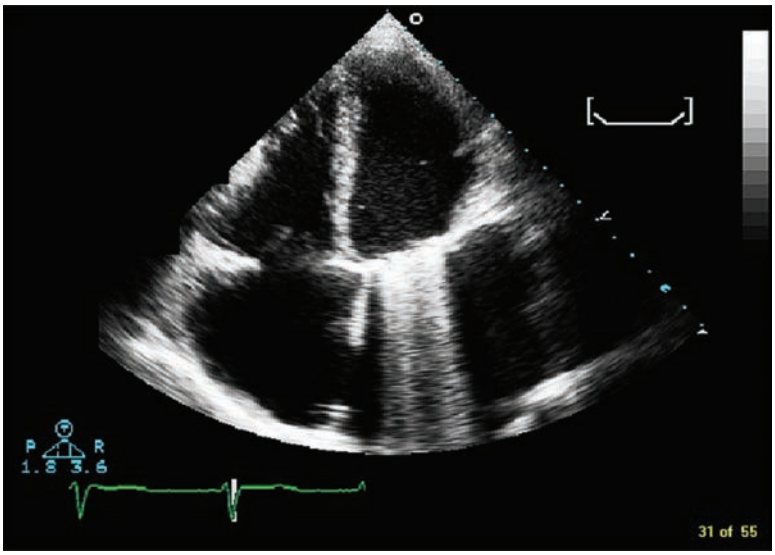

Figure 5.58

5.59. What intervention can potentially change the mitral inflow pattern seen in the images in Figure 5.59?

- **A.** Diuresis
- **B.** Control of severe hypertension
- **C.** Correction of severe anemia
- **D.** All of the above

5.60. What is the abnormality shown in Figure 5.60?

- **A.** Thoracic aortic aneurysm
- **B.** Cor triatriatum
- **C.** Artifact
- **D.** Dilated left PA

5.61. What is the patient in Figure 5.61 likely to have?

- **A.** Mitral valve prolapse
- **B.** Elevated LV EDP
- **C.** HOCM
- **D.** Severe AR

5.62. What does the mitral valve motion in the patient in Figure 5.62 suggest?

- **A.** Atrial fibrillation
- **B.** Elevated LV EDP
- **C.** Mitral valve prolapse
- **D.** Severe AR

5.63. What is the aortic valve m-mode in Figure 5.63 suggestive of?

- **A.** AS
- **B.** HOCM
- **C.** Congestive heart failure
- **D.** Hypertension

5.64. What is the patient in Figure 5.64 likely to have?

- **A.** Mild AR
- **B.** MS with high LA pressure
- **C.** Acute severe AR
- **D.** Severe MR

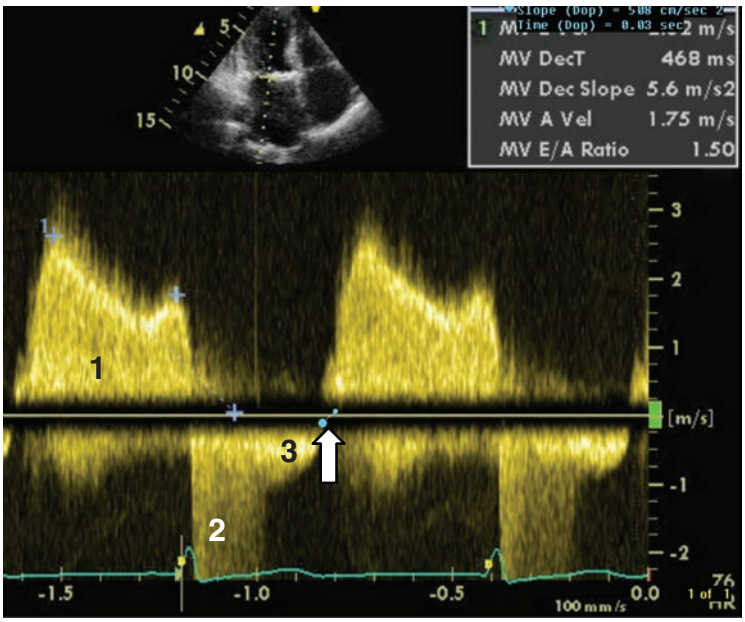

Figure 5.64

5.65. The patient in Figure 5.65 has MS with which of the following?

- **A.** High LA pressure
- **B.** Hyperdynamic LV
- **C.** Severe LV systolic dysfunction
- **D.** MR

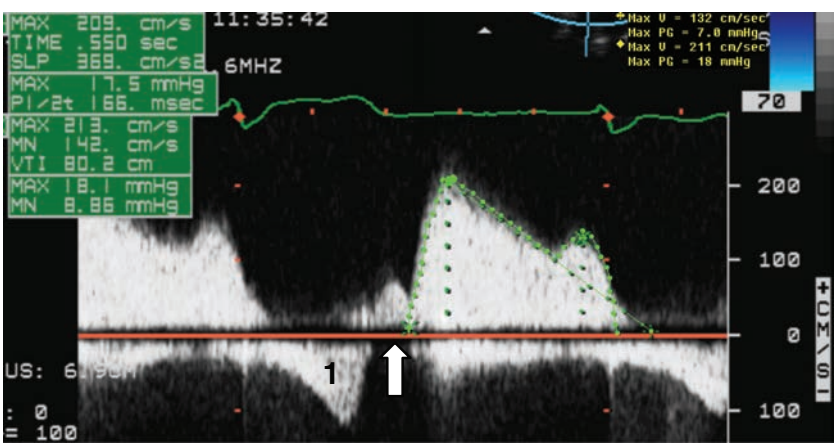

Figure 5.65

5.66. What is the continuous-wave Doppler signal in Figure 5.66 suggestive of?

A. Severe AR
B. MS
C. Pulmonary hypertension
D. Severe PR

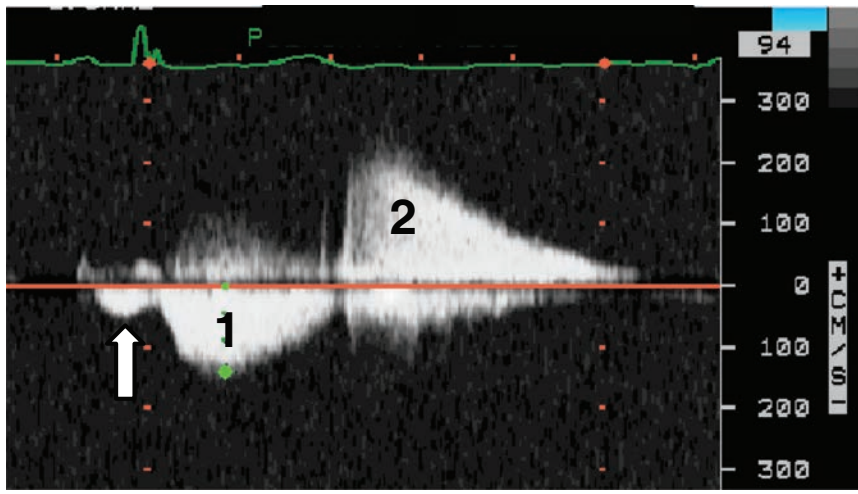

Figure 5.66

5.67. What is the continuous-wave signal in Figure 5.67 from a 22-year-old woman with a history of heart surgery during infancy indicative of?

A. Severe AS
B. Severe PS
C. Severe PS and PR
D. Severe pulmonary hypertension

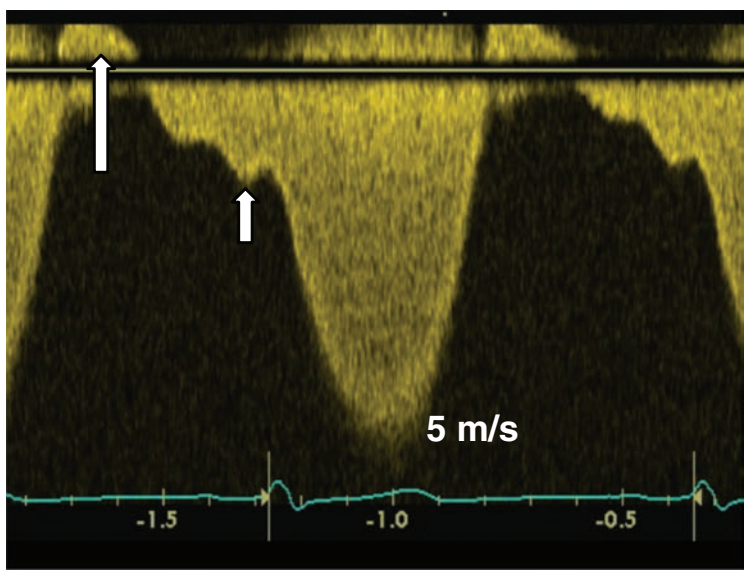

Figure 5.67

5.68. What was the signal in Figure 5.68 obtained from?

A. Apical window
B. Parasternal window
C. Suprasternal window
D. Subcostal window

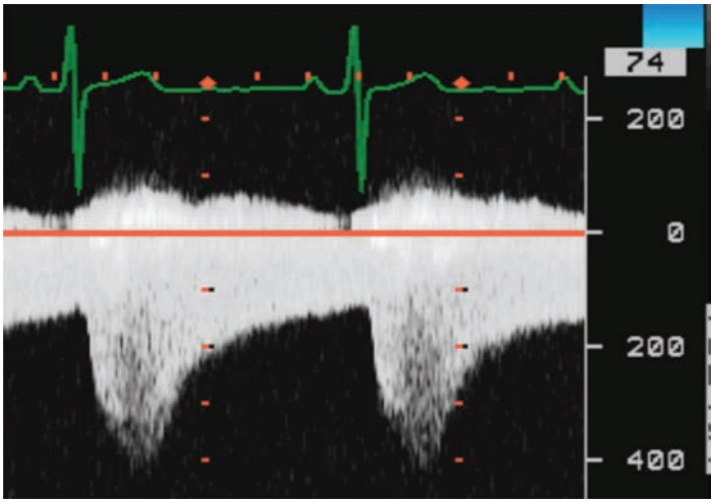

Figure 5.68

5.69. What condition does the patient in Figure 5.69 have?

A. PA branch stenosis
B. PR
C. Patent ductus arteriosus (PDA)
D. None of the above

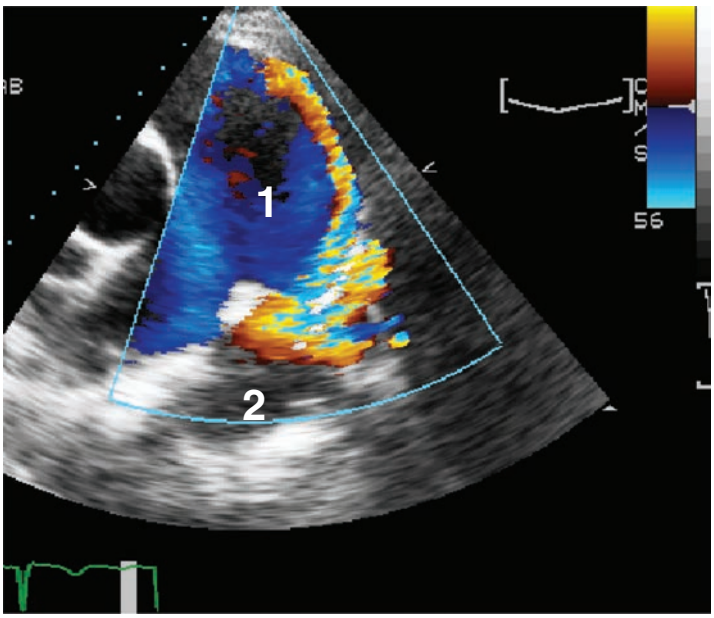

Figure 5.69

5.70. In Figure 5.70, the flow obtained on TEE from the descending thoracic aorta is indicative of what?

A. Aortic coarctation
B. PDA
C. Normal flow in intercostal artery
D. Severe AR

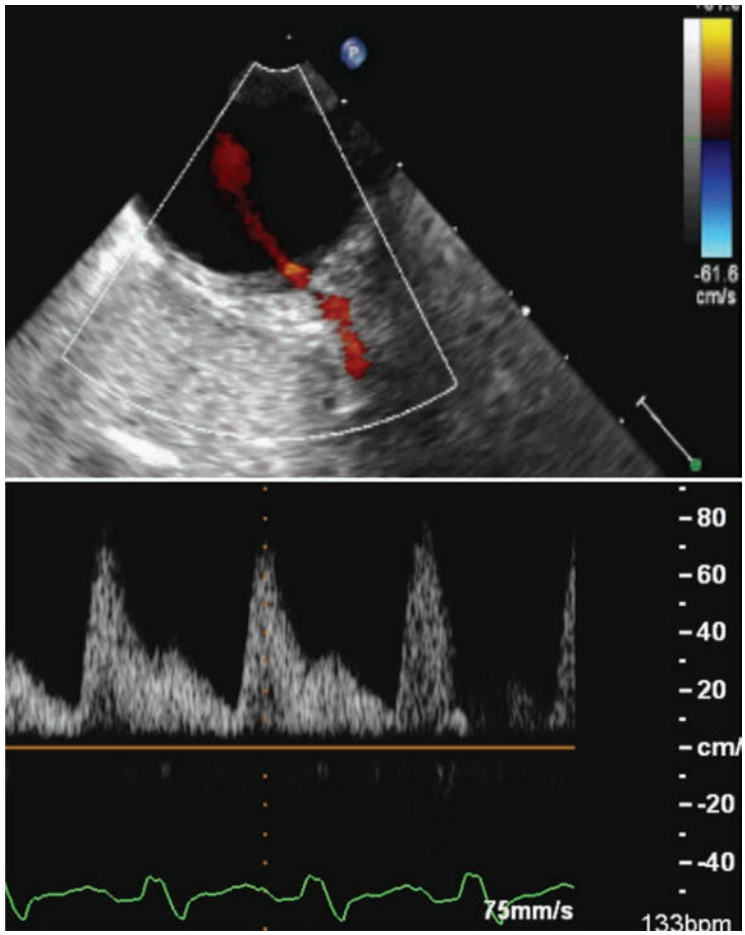

Figure 5.70

5.71. In Figure 5.71, the flow from this subcostal view is indicative of what?

A. Large ASD
B. Severe MR
C. MS
D. Tricuspid stenosis

5.72. Figure 5.72 is a recording of flow across the pulmonary valve using pulsed-wave Doppler in a patient with severe dyspnea. What is the likely diagnosis?

A. Pulmonary hypertension
B. PS
C. PR
D. Large ASD

5.73. Figure 5.73 shows a patient with what condition?

A. LV systolic dyssynchrony
B. LV diastolic dyssynchrony
C. Good LV synchrony
D. None of the above

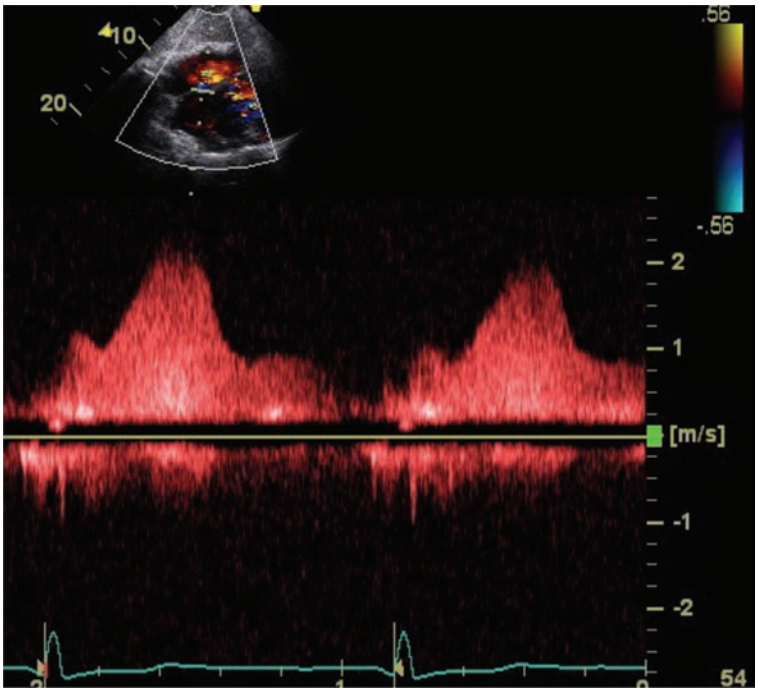

Figure 5.71

A. Aortic aneurysm
B. IVC
C. Dilated azygos vein
D. Mirror image artefact

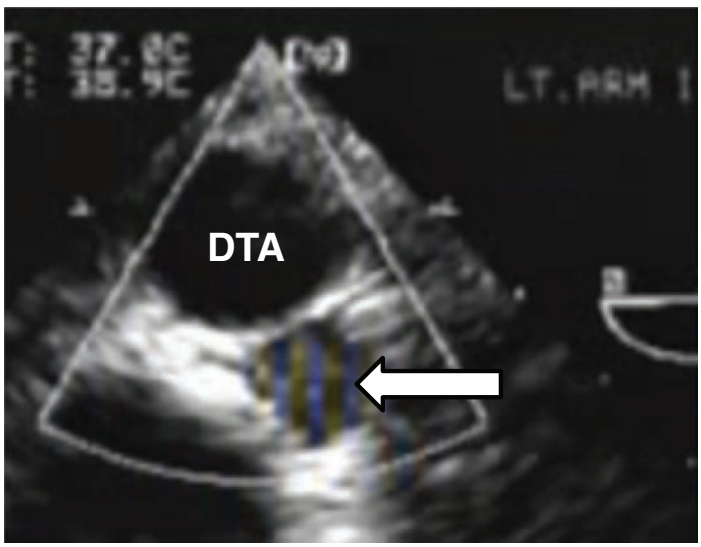

Figure 5.78

Answers

5.1. C. Decrease sector angle.

Increase in frame rate occurs with reducing sector angle and reducing depth, the former by reducing scan lines and the latter by reducing ultrasound transit time. It is independent of transmit frequency and power.

5.2. C. Beam focusing.

Focusing increases lateral resolution. Increasing transducer diameter and increasing frequency also increase lateral resolution.

5.3. D. Increasing transmit frequency.

Increasing the transmit frequency will reduce the wavelength and hence the spatial pulse length. This will increase the pulse repetition frequency and the axial resolution. Beam diameter and focusing have no effect on axial resolution.

5.4. C. Ability to record higher velocities.

Aliasing and range specificity are properties of pulsed-wave Doppler. Continuous-wave Doppler is not associated with range ambiguity. Continuous-wave Doppler will also permit recording of higher velocities than pulsed-wave Doppler will, as it is not limited by the pulse repetition frequency as transmitted ultrasound is continuous.

5.5. C. Severe MR.

Jet area underestimates the severity of MR as the driving pressure is low. The regurgitant flow rate is approximately 200 cm^3/s. Because of low left ventricular (LV) systolic pressure of 80 mmHg, the MR velocity would be in the range of 4 m/s (400 cm/s) assuming a left atrial (LA) pressure of 16 mmHg. Hence, the effective regurgitant orifice (ERO) area would be about 200/400, or 0.5 cm^2. Hence, in an intraoperative setting, it is important to bring up the blood pressure before performing MR quantitation.

5.6. D. Increasing the blood pressure.

Underestimation of MR can occur due to undersampling in the setting of low frame rate (increasing sector angle and depth) and high heart rates. Increasing blood pressure will increase the driving pressure across the mitral valve, and hence the jet size will increase because of a combination of an increase in regurgitation as well as higher kinetic energy in the jet imparted by higher driving pressure. Jet size is proportional to its kinetic energy. Wall-hugging jets tend to be smaller than free jets because of loss of jet energy to the wall.

5.7. A. 5.5 L/min.

The stroke volume equals the cross-sectional area multiplied by the TVI of the LVOT, which is $3.14 \times 1 \times 1 \times 25 = 78$ cm^3. Cardiac output equals stroke volume multiplied by heart rate: $78 \times 70 = 5.5$ L/min.

5.8. D. Cannot be calculated based on data given.

In a patient with serial stenosis in close proximity, the continuity equation cannot be applied because of difficulty in obtaining precise subvalvular velocity and cross-sectional area of the flow in the LVOT. In a person without SAM the cross-sectional area of subvalvular flow is roughly equal to the cross-sectional area of the LVOT. Subvalvular obstruction will result in flow streams such that the cross-sectional area of flow is less than the anatomic LVOT area.

5.9. C. Severe.

Regurgitant volume is $140 - 80 = 60$ cm^3/beat and regurgitant fraction is $60/140 = 43\%$. ERO area is regurgitant volume/TVI of aortic signal: $60/100 = 0.6$ cm^2. The regurgitant fraction in AR depends not only on ERO, but diastolic period and driving pressure. Hence, the ERO area is a more reliable index of AR volumetric severity. An ERO area of ≥ 0.4 cm^2 is indicative of severe AR.

5.10. A. Overestimate the valve area.

In the presence of severe AR, the pressure half-time is decreased due to a rise in LV diastolic pressure produced by AR. Hence, in the calculation of mitral valve area by the pressure half-time method the valve area will be overestimated or MS severity will be underestimated. Pressure half-time is decreased due to increase in late LV diastolic pressure, causing a reduction in the LA–LV pressure gradient.

5.11. A. Severe AS.

This is an AS signal. Please pay attention to the onset of the signal, which is sometime after the onset of QRS indicative of signal arising during ejection. Typically a peak gradient >80 mmHg and a mean gradient of 40 mmHg are indicative of severe AS, though these are flow dependent. Valve area is a better indicator of severity of AS. MR signal starts with QRS. Tricuspid regurgitation (TR) signal in severe pulmonary hypertension also starts with QRS. (See Box 5.3.)

5.12. C. 0.5 cm^2.

By the continuity equation $A1 \times V1 = A2 \times V2$. Hence the aortic valve area ($A2 = A1 \times V1/V2$) is approximately $3.14 \times 1 \times 1 \times 1/6 = 0.5$ cm^2.

5.13. A. Wide-open pulmonary regurgitation (PR).

Note the rapid deceleration of the PR signal with rapid equilibration of late diastolic pulmonary artery (PA) and right ventricular (RV) pressures. The increased systolic flow velocity is due to increased flow secondary to wide-open PR. Note that from this TEE view you are looking at the pulmonary valve from above (i.e., the PA side), unlike a parasternal short-axis view.

5.14. B. Elevated LA pressure with elevated EDP.

The rapid D-wave deceleration with time <170 ms indicates high LA pressure. In addition, the S wave is smaller than the D wave. The atrial reversal wave duration is about 220 ms. The normal duration is about 80–100 ms. This is due to increased duration of atrial systole having to pump against elevated LV EDP. Pulmonary vein atrial regurgitation duration greater than mitral A-wave duration is indicative of high LV EDP.

5.15. B. High LA pressure.

This inflow pattern shows a high E/A ratio. The deceleration time is also short, suggestive of high LA pressure. In pure atrial mechanical failure the E wave is normal, with diminished mitral A-wave amplitude.

5.16. B. Tricuspid atresia.

The atretic tricuspid valve is shown. There was no atrial septal defect (ASD), and outflow from right atrium was through right atrium to PA shunt. Patient also had a superior vena caval-right PA shunt. Both were patent. This would need low pulmonary vascular resistance and low PA pressure. This patient has a nonrestrictive ventricular septal defect (VSD), and hence RV systolic pressure would be the same as LV systolic pressure and to maintain low PA pressure the RV outflow

should be minimal or nonexistent. In this patient this was accomplished surgically with banding of the PA.

Right atrial thrombus in this patient with tricuspid atresia is due to stasis.

5.17. B. Ostium secundum ASD.

Primum ASD would be in the lower part of the septum and may involve anterior mitral leaflet and A–V conduction. Sinus venosus ASD is in the upper septum near the superior vena cava and may also be associated with anomalous drainage of the right upper pulmonary vein. There is also a rare type of sinus venosus ASD in the vicinity of the inferior vena cava (IVC). In unroofed coronary sinus, the shunt is from left atrium to right atrium through a posterior defect into the coronary sinus such that flow goes through the coronary sinus into the right atrium.

5.18. D. Flow across ASD.

This biphasic flow with a systolic–early diastolic component and LA contraction is typical of ASD flow. Pulmonary vein flow and superior vena cava flow would be triphasic, with distinct systolic and diastolic flows with reversal and atrial contraction. Mitral flow has only diastolic components with early and late diastolic components.

5.19. A. 12.8 L/min.

The shunt flow per beat can be calculated as the product of the TVI of the shunt flow and the anatomic area of the defect. This would be $39 \times 3.14 \times 1.5 \times 1$ cm^3/beat (183 cm^3). This multiplied by the heart rate gives the shunt flow per minute.

5.20. A. Rheumatic heart disease.

The patient has classic rheumatic MS. The anterior leaflet is thin with a hockey-stick appearance in diastole, which occurs due to commissural fusion. In degenerative MS there is severe annular calcification, which extends into the leaflets causing stenosis. In fen–phen valvulopathy the leaflets are thick and fibrosed and may result in both MS and MR. Ischemic involvement of the left ventricle without papillary muscle rupture causes restriction of closure and functional MR and not MS. Also note severe smoke-like echo or spontaneous echo contrast in the left atrium and layered thrombus in the body of the left atrium at the top of the image.

5.21. D. Bicuspid aortic valve.

This patient has Epstein's anomaly. Note the downward displacement of the septal leaflet of the tricuspid valve compared with the mitral leaflet attachment. A displacement of >8 mm/m^2 is suggestive of Epstein's. The septal leaflet may be large, sail-like, and adherent to the ventricular septum. This is frequently associated with ASD, right-sided accessory pathway, and TR, but not with bicuspid aortic valve.

5.22. A. Normal mitral valve motion.

This M mode is suggestive of normal mitral valve motion. There is normal mitral valve opening with greater early diastolic opening compared with opening associated with LA contraction. Valvular MS would cause mitral leaflet thickening, reduced opening and reduced ejection fraction (EF) slope, and paradoxical anterior motion of the posterior leaflet during diastole because of commissural fusion. Severe AR may cause fluttering of the anterior mitral leaflet and premature closure of the anterior mitral leaflet as the mitral valve opening is flow dependent. Features

of high LA pressure will include predominant early opening, rapid EF slope, and a smaller opening with atrial contraction mirroring the transmitral inflow pattern.

5.23. C. Biventricular pacemaker or implantable cardioverter-defibrillator (ICD).

The arrow here depicts a lead in the coronary sinus and is consistent with a biventricular pacemaker.

5.24. A. LA appendage.

The structure denoted by the arrow is the LA appendage. This is separated from the left upper pulmonary vein, which is to the posterior with a ridge popularly known as the "coumadin ridge" because of the potential to be misinterpreted as a thrombus. Because this ridge is echo reflective, sometimes one can see thrombus-like artifacts in the appendage as mirror image artifacts. Though the appendage is clearly visualized here, this view alone is not sufficient to rule out a thrombus. Multiple tomographic views have to be obtained through the appendage in its entirety as the appendage may have multiple lobes.

5.25. B. Subvalvular AS.

The structure attached to the septum below the aortic valve is a classic subaortic membrane. Occasionally, vegetations can be seen here due to seeding from the aortic valve. This is a diastolic frame, and hence aortic valve opening cannot be evaluated.

5.26. A. Left heart failure.

The mitral inflow shown here is indicative of high LA pressure. Though the patient is in atrial fibrillation with only E wave, the E wave deceleration is very rapid, with a deceleration time of 100 ms.

5.27. D. Dilated cardiomyopathy.

There is a four-chamber dilatation. There is no increase in wall thickness to suggest HOCM. In ASD both the right ventricle and the right atrium will be dilated due to volume overload with normal LA and LV size. The tricuspid valve position is normal and hence does not support the diagnosis of Ebstein's anomaly.

5.28. A. P2 tethering.

This is an apical long-axis view, showing A2 and P2 scallops of the mitral valve. The MR jet is directed posterolaterally toward P2, consistent with P2 tethering. A similar jet direction can also occur in A2 prolapse, but both leaflets coapt distal to the plane of the mitral annulus. Bileaflet prolapse of equal magnitude will result in a central jet.

5.29. A. Penetrating injury to the interventricular septum.

A defect is seen in the ventricular septum. This patient had a penetrating injury to the septum. The image does not support the presence of mitral valve prolapse or hypertrophic septum.

5.30. A. AS and AR.

Unlike the MR signal, the AS signal occupies only the ejection period and is absent during the isovolumic contraction time. Hence, the signal starts a few milliseconds after the QRS. The diastolic velocity is too high for MS. This order of gradient and LA pressure would be incompatible with life. VSD flow is predominantly systolic with a presystolic component caused by atrial contraction. The gradient across a coarctation is systolic; the duration increases with greater degrees

of stenosis and there may be a diastolic gradient. However, both the systolic and diastolic components will be in the same direction.

5.31. B. MS and MR.

Note that in TEE, from mid-esophageal location, the MR jet is directed toward the transducer.

5.32. A. Severe AR.

The aortic leaflets are thickened with rolled-up edges and a central coaptation defect in end diastole. This anatomy would be associated with wide-open AR, as the regurgitant orifice is visible by anatomic imaging. AS cannot be diagnosed by a diastolic frame. HOCM typically causes mid-systolic closure of the aortic valve, best visualized by M mode. Aortic dissection may cause AR by one of several mechanisms: dilatation of sino-tubular junction, leaflet tethering, extension of hematoma into the aortic leaflet causing it to prolapse, or as a result of a primary problem such as bicuspid aortic valve or annulo-aortic ectasia.

5.33. B. Chronic severe MR.

The MR signal density is more than 60% of the mitral inflow signal. This correlates with a volume of regurgitation. In addition, the mitral inflow velocity is increased without a slow deceleration. A slow deceleration would indicate significant MS. Despite severe MR, the profile of the MR signal is quite rounded without the rapid deceleration that would typically be seen in acute severe MR, because of the large LA V wave, the so-called "V wave cutoff sign." Note that the heart rate is 151 bpm. At rapid heart rates, MR may be grossly underestimated by color Doppler due to limited temporal resolution and continuous-wave Doppler is very helpful.

5.34. A. Central venous catheter-associated infection.

This bicaval transesophageal view shows a large mass in the superior vena cava, which is typically associated with a central catheter-associated thrombus or vegetation. This most likely is the cause of his sepsis and endocarditis. In addition, there is a possible defect at the superior portion of the fossa ovalis, suggesting a patent foramen ovale (PFO). This patient had a large PFO by color and contrast echocardiography, allowing paradoxical embolization of the bacterial mass to cause left-sided endocarditis, escaping the protective filtration mechanism offered by the lung.

5.35. A. Aortic valve vegetation.

The mass on the aortic valve is suggestive of mass on the left ventricular side of the aortic valve. This is suggestive of vegetation. Also, there is prolapse of the noncoronary cusp, causing significant AR, and this is due to leaflet destruction with endocarditis. The other mechanism for prolapse could be a bicuspid aortic valve with prolapse of the larger cusp. Node of Arantius, as the name suggests, is a nodular thickening of the central portion of the leaflet edge and is best visualized from the short-axis view of the valve. Lambl's excrescences are thin filamentous structures attached to the leaflet margin. There is no evidence of aortic dissection or intramural hematoma in this patient.

5.36. A. HOCM.

This late peaking dagger-shaped signal is typical of SAM caused by HOCM. This occurs due to the dynamic LVOT obstruction increasing through systole. Critical

valvular AS is unlikely, as in this case the velocity is likely to be higher (unless cardiac output is very low) and the signal contour would be more rounded. Acute MR gives rise to an early peaking signal with a rapid deceleration because of a large LA V wave, the so-called V wave cutoff sign. In LV cavity obliteration this signal will be much later peaking, with a gradient only in the very late part of systole when there is very little blood left in the distal LV cavity.

5.37. A. Bioprosthetic tricuspid valve.

This patient has Hancock porcine bioprosthetic tricuspid valve. The struts of the bioprosthetic valve are well seen. An annuloplasty ring would be seen as a small rounded structure in cross-section at the tricuspid annulus only.

5.38. B. Third heart sound.

The mitral inflow is suggestive of high LA pressure. The mitral E/A ratio is >2 and deceleration time is 60 ms, indicating very high LA pressure. The calculated E-wave deceleration calculated from the E-wave amplitude and its time (velocity/time) is about 20 m/s^2. A rate of deceleration of >8–9 m/s^2 is likely to result in S3. Age is relevant, as such a filling pattern in young children is normal because they have extremely efficient LV relaxation, which would result in physiological S3. S4 results from a prominent atrial-filling wave in a stiff ventricle, and in a summation gallop the E and A waves are fused. This patient has no MS, and hence opening snap is unlikely.

5.39. B. Severe MR.

The temporal continuity of the systolic signal with the inflow signal suggests its origin at the mitral valve. The AS signal would occupy only the ejection period, being separated from the mitral inflow signal by isovolumic contraction and relaxation periods. A small VSD may result in a holosystolic signal, but generally has a presystolic component associated with LA systole, and generally this flow is directed toward the transducer from most of the imaging windows.

5.40. C. 80 mmHg.

The TR velocity is 4 m/s, yielding an RV–RA systolic gradient of 64 mmHg. With an RA pressure of 20 mmHg the RV systolic pressure would be about 80 mmHg, which would be the same as the PA systolic pressure in the absence of significant PS.

5.41. A. Acute severe AR.

The late diastolic frame in Figure 5.41 shows diastolic MR. There is also AR by color. The mitral valve is closed prematurely. This combination of findings is consistent with acute severe AR. A smaller AR jet in late diastole was due to late diastolic equilibration of aortic and LV pressures. Diastolic MR results from the receipt of AR volume in a left ventricle with high operating end diastolic stiffness.

5.42. B. Acute AR.

The Doppler flow suggests premature closure of the mitral valve with lack of A wave despite being in sinus rhythm. This is pathognomonic of acute AR causing rapidly rising LV diastolic pressure due to failure to accommodate a large acute volume overload. In acute AR the left atrium would still be contracting, but would be unable to eject against an acute increase in afterload. Pulmonary vein flow profile in this patient would show a prominent AR wave, and the tricuspid inflow would still have the A wave. Acute MR and VSD would not eliminate the

A wave unless the patient had a recent episode of atrial fibrillation and the atrium is stunned.

5.43. C. Severe AR.

A prominent holodiastolic flow reversal suggesting retrograde flow in the aorta is seen. This flow would also cause Duroziez's murmur by physical exam due to the turbulence produced by partial occlusion by the finger, which would produce a diastolic murmur in the proximal femoral artery. Coarctation and middle aortic syndrome diminish pulsatility in the distal aortic flow and the flow becomes continuous due to flow through collaterals. Though HOCM can produce mid-systolic closure of the aortic valve, it does not produce any flow disturbance in the distal aorta.

5.44. A. Noncompaction of the left ventricle.

The inferolateral wall of the left ventricle in this patient is heavily trabeculated; noncompacted (trabeculated) to compacted wall thickness ratio is more than 2 : 1. This is highly indicative of noncompaction of LV myocardium, which is a developmental disorder causing congestive heart failure. In the other three conditions the LV myocardium would be thicker, either due to infiltration or increased myocardial mass.

5.45. A. IVC–right atrium junction.

Part of the proximal IVC is seen with entry of saline contrast, in the longitudinal plane from a TEE. With this orientation, caudal structures are seen on the left and cephalad structures are seen on the right. This patient has a prominent Eustachian valve, and in a patient with a prominent Eustachian valve, in a low esophageal view, where left atrium is not seen, this junction may be mistaken for an ASD. This patient was referred from an outside facility with that mistaken diagnosis from a TEE.

5.46. A. ~200 cm^3/s.

The regurgitant flow rate equals $2\pi r^2$ times the Nyquist limit. Here, the PISA radius is 0.9 cm and the Nyquist limit is 38 cm/s. Regurgitant flow rate is $2 \times 3.14 \times 0.9^2 \times 38 \approx 200$ cm^3/s.

5.47. C. Late-peaking systolic murmur increased by Valsalva's maneuver and normal A2.

This patient clearly has SAM of the anterior mitral leaflet causing LVOT obstruction. As the SAM increases in late systole, the gradient velocity and turbulence are more in late systole, causing a late-peaking late systolic murmur. SAM is increased by LV volume reduction and vasodilatation. A2 is preserved in these patients, in contrast to patients with severe AS, who may also have late-peaking systolic murmur.

5.48. A. HOCM.

This patient has HOCM with dynamic LVOT obstruction caused by SAM, which causes a late-peaking systolic gradient, increased by Valsalva's maneuver and amyl nitrate inhalation. The gradient would also be increased by positive inotropic agents and vasodilators and decreased by an increase in afterload, with vasoconstrictors or handgrip. In addition to HOCM, SAM can occur in volume-depleted states with small left ventricle cavity and also after surgical mitral valve repair in patients with long anterior and posterior leaflets, especially if a small annuloplasty ring is used.

5.49. A. Apical HOCM.

This patient has disproportionately thickened LV apical myocardium typical of apical HOCM. This results in a spade-shaped LV cavity in diastole. These patients also have giant T-wave inversions in their chest leads. In hypertensive heart disease, LV hypotension is more uniformly distributed. Endomyocardial fibrosis causes apical obliteration due to endocardial thickening rather than myocardial thickening.

5.50. C. PFO closure device.

The image shows two parallel discs sandwiching the upper atrial septum. The RA disc is larger than the LA disc. This is suggestive of an Amplatzer PFO closure device. In an ASD closure device, the LA disc is larger than the RA disc. Patch repair of the septum will not show the triple-layer morphology as seen here.

5.51. C. Vegetation on a bioprosthetic valve.

This is a short-axis view of the tricuspid valve, best obtained from a proximal gastric location, with clockwise probe rotation at about 20–30°. The sewing ring of the prosthetic valve is clearly seen here, and there is a mass attached to the leaflets indicative of vegetation.

5.52. A. Paradoxical embolism.

Figure 5.52 shows the interatrial septum with a large PFO in its typical location. The color flow shows left to right flow. This flow would reverse under situations of increased RA pressure, such as straining, coughing, and right heart failure. The orientation of the opening is favorable for thrombi originating in the IVC region to traverse the PFO to the left atrium even in the absence of raised RA pressure.

5.53. C. Fistulous communication between aorta and right ventricle.

In addition to the fistulous communication, Figure 5.53 also shows AR. Fistulous communications generally result from rupture of an aortic root abscess. This may result in communications to the right atrium, right ventricle, PA, or the LVOT. Other local complications include abscess of mitral aortic intervalvular fibrosa, leaflet aneurysm, and perforation of the anterior mitral leaflet. One may also get an abscess in the ventricular septum, causing a VSD after rupture.

5.54. B. Pulmonary valve endocarditis.

This is a mid-esophageal image showing the aortic valve in short axis in the center and the RV inflow and outflow wrapped around it akin to the short axis of the aortic valve from a parasternal view. There is a large mass attached to the pulmonary valve consistent with vegetation. This is the likely source of his lung abscesses.

5.55. A. Coronary sinus.

Figure 5.55 is a low esophageal view partially cutting through the posterior A–V groove showing the coronary sinus.

5.56. C. Severe.

This is severe as judged by jet size, vena contract, and PISA radius. In addition, the two-dimensional image shows lack of tricuspid leaflet coaptation, leading to wide-open TR. The mechanism is tricuspid annular dilatation, and hence is functional, probably secondary to previous pulmonary hypertension due to mitral valve disease resulting in RV and RA dilatation, thus stretching the tricuspid annulus. This is repairable with tricuspid annuloplasty. Also note the partly seen mitral

prosthesis. TR quantitations by using the three components of the jet are not well validated.

5.57. C. Moderate or severe pulmonary hypertension.

In patients with wide-open TR, the tricuspid valve may be fairly nonrestrictive, allowing right ventricle and right atrium to behave virtually as a single chamber during systole. In such a situation the TR pressure gradient cannot reliably be calculated using the simplified Bernoulli equation as a considerable amount of energy may be expended in causing acceleration of the TR jet. In addition, RA pressure may be very high, leading to underestimation of PA pressure. In this example, one can count the number of aliases to estimate the TR velocity at the vena contracta. There are four aliases, corresponding to a velocity of 69 cm/s × 4; that is, 2.76 cm/s. Though the pressure gradient is 30 mmHg, the patient is likely to have very high RA pressure (i.e., 20–30 mmHg), and because of wide-open TR the TR pressure gradient would have underestimated the pressure gradient. Hence, the PA systolic pressure is at least moderate but more likely to be in the severe range in the absence of PS. In such patients, careful examination of the pulmonary regurgitant jet to get an estimate of PA diastolic pressure would be helpful.

5.58. D. Replacement with a mechanical valve.

This prosthesis probably is a bileaflet valve in view of the two areas of reverberations seen in the left atrium. A bioprosthetic valve would show struts in the periphery and thin leaflets in the center, unless calcified. An annuloplasty ring is an echo-dense structure at the base of the mitral leaflet on the LA side with intact leaflets. This ring can be partial or complete. An Alfieri stitch can be central or asymmetric and is simply a stitch that focally unites the tips of anterior and posterior leaflets and converts the mitral orifice into a double orifice, best seen in short-axis view.

5.59. D. All of the above.

Pre-intervention mitral flow is indicative of high LA pressure. This pattern is seen despite a heart rate of 92 bpm, as faster heart rates result in atrial predominance of ventricular filling. Post intervention the mitral flow is suggestive of impaired left ventricular relaxation, which is consistent with normal or low mean LA pressure. Note that the heart rate is slower at 62 bpm. This patient had dilated cardiomyopathy with severe functional MR, which responded to diuresis and afterload reduction with a reduction of LV size and elimination of MR. Uncontrolled hypertension will reduce LV ejection performance, increase LV size, and give rise to MR, as myopathic ventricles are exquisitely sensitive to afterload. As these patients have little or no functional reserve, anemia has a serious and deleterious effect on hemodynamics because of a reduction in oxygen-carrying capacity and a demand for higher cardiac output.

5.60. A. Thoracic aortic aneurysm.

The thoracic aorta runs posterior to the left atrium, is rounded, and on dynamic imaging is pulsatile. Turning the imaging plane by 90° would show the long axis of the descending aorta. The membrane of cor triatriatum separates the pulmonary venous chamber from the lower part of the atrium and is best seen from parasternal long-axis and apical views. The location is across the left atrium. Left PA is not seen in the posterior mediastinum.

5.61. C. HOCM.

Note the SAM of the anterior mitral leaflet starting in midsystole. The SAM narrows the LV outflow tract in a dynamic manner, producing LV outflow obstruction and gradient. Elevated LV EDP is not an unreasonable response as deceleration of mitral A wave is slow, though not a classical B hump. Mitral valve prolapse results in late systolic sagging of the mitral valve, not anterior motion. Severe AR with a posteriorly directed jet on to the anterior mitral leaflet results in diastolic fluttering.

5.62. B. Elevated LV EDP.

Note the prominent B hump after the A point of mitral valve motion. In atrial fibrillation, there is loss of A wave. Also see explanation for Question 5.61.

5.63. C. Congestive heart failure.

This is typical of pulsus alternans, which occurs in severe systolic heart failure. Note there is reduced opening and duration of opening of the aortic valve with every other beat, and this results from reduced stroke volume with every other beat. Also note that,in this instance, pulsus alternans was triggered by a premature ventricular complex. In AS, there is leaflet thickening and reduced opening. In HOCM, there may be midsystolic closure of the aortic valve. Hypertension does not produce any characteristic changes in aortic valve motion.

5.64. B. MS with high LA pressure.

The diastolic signal "1" is that of MS, and this patient is in sinus rhythm as there is an A wave. The peak diastolic gradient is about 30 mmHg and mean gradient is 18 mmHg at a heart rate of 76 bpm, and this indicative of severe MS. The arrow points to isovolumic relaxation time (IVRT), which was 30 ms, indicating high LA pressure or large LA "V" wave. "2" indicates partial MR velocity, as it is contiguous with ending of the MS signal, and "3" indicates LV outflow and the gap between that and mitral inflow, which is indicated by the arrow in IVRT.

5.65. B. Hyperdynamic LV.

Systolic signal denoted by "1" is not MR, but due to LV cavity obliteration as it is late peaking and hence indicates a hyperdynamic LV. It also occurs during ejection phase, unlike an MR signal. IVRT indicated by the arrow is 110 ms (time between small marks is 200 ms and two vertical lines is 1 s), and this indicates normal LA pressure. IVRT is the Doppler equivalent of the auscultatory A2–OS interval; that is, interval between aortic component of second heart sound and opening snap in MS. A short A2–OS interval indicates severe MS.

5.66. D. Severe PR.

Signal "2" is early diastolic following an ejection flow "1" suggestive of origin at a semilunar valve. The arrow points to forward flow across the semilunar valve with atrial systole, and this can occur only at the pulmonary valve with normal PA pressure. If the PA pressure is high, atrial systole cannot generate a forward flow even when there is late diastolic equilibration of pressures between PA, right ventricle, and right atrium. For the same reason, you do not get forward flow across the aortic valve in severe AR as aortic diastolic pressure is too high and high LV diastolic pressure may cause premature closure of the mitral valve. The diastolic flow is of low velocity and ends in mid-diastole, indicating severe PR with normal PA pressure.

5.67. C. Severe PS and PR.

This patient in fact had a bovine jugular nonvalved conduit between the right ventricle and PA for pulmonary atresia in a foreign country during infancy and presented with shortness of breath and edema. As the conduit has become too small for her body size and flow requirements, it was functionally stenotic, resulting in a very high systolic gradient. The longer arrow points to the PR signal. The PR is severe and also it rapidly decelerates with equilibration of pressures between PA and right ventricle. Shorter arrow indicates forward flow with RA systole; this indicates normal PA pressure.

5.68. C. Suprasternal window.

This is a classic flow because of severe coarctation of the aorta with systolic and diastolic components. The signals are negative or flow is going away from the transducer. This signal is obtained from the suprasternal window.

5.69. C. Patent ductus arteriosus (PDA).

This is a typical PDA flow obtained from a parastenal short-axis basal view with clockwise rotation of the probe to show PA and branches. "1" indicates dilated main PA and "2" arch/descending aortic junction from which flow is occurring into PA. Note this is a diastolic frame (see marker on electrocardiogram) and flow is into the main PA; hence, not left PA branch stenosis.

5.70. A. Aortic coarctation.

Note that the flow is into the aortic lumen throughout the cardiac cycle, indicative of retrograde flow in the intercostal artery. This occurs in collateral dependent distal perfusion as it occurs in severe aortic coarctation. This patient had interrupted aorta. In severe AR, holodiastolic retrograde flow occurs in the aortic lumen.

5.71. B. Severe MR.

This flow is across the foramen ovale due to excessive stretching produced by high atrial pressures. The flow is from left atrium to right atrium, and note that the highest velocity is in late systole, indicative of a large LA "V" wave which occurs in severe MR. In large ASD, flow will be nonrestrictive across the defect, resulting in very low or transient pressure gradients.

5.72. A. Pulmonary hypertension.

This is a typical "flying W sign" associated with pulmonary hypertension. Midsystolic deceleration occurs because of rapidly returning reflected pressure waves secondary to a stiffer PA that occurs when it operates under high pressure. These is no PR signal and no continuous-wave signal to assess if there is a gradient across the pulmonary valve. The velocity of the signal is under 1 m/s, indicating normal amount of PA flow, and this inconsistent with a large ASD. Large ASD is associated with increased PA flow.

5.73. A. LV systolic dyssynchrony.

Tissue Doppler or tissue velocity images are shown here. Focal velocity profiles of medial (yellow) and lateral annulus (green) are produced offline by placing samples in these regions. Note that the peak of lateral annulus velocity is about 150 ms after the medial annulus velocity peak, suggestive of septolateral mechanical dyssynchrony. A septolateral delay of >65 ms is indicative of LV dyssynchrony. There was good diastolic synchrony, as judged by annular E wave velocity profiles.

5.74. A. LV strain.

Note that the units are in percent, which is percentage shortening compared with original length. Normal myocardial strain is 15–20%, very similar to percentage sarcomeric shortening during contraction of cardiac muscle cell.

5.75. C. Aortic subvalvular membrane.

This is a classic example of membranous subaortic stenosis. Also note part of this circumferential membrane on the LV side of the anterior mitral leaflet. The image also shows the aortic valve (left-pointing arrow) and the SAM of the anterior mitral leaflet (right-pointing arrow).

5.76. A. Coronary artery.

This was anomalous circumflex coronary artery originating from right coronary artery with retroaortic course between aorta and left atrium. Note that it is small and perfectly circular unlike an abscess, which tends to have irregular edges and inflammatory thickening or other sequelae around it. One can study the course of the vessel by imaging this structure in different imaging planes. Coronary sinus would be in the posterior atrioventricular (AV) groove.

5.77. A. Dilated coronary sinus and dextrocardia.

Note opacification of the structure at the AV groove with saline contrast, indicating anomalous connection of left or right or entire superior vena cava into coronary sinus (as it is not specified which arm was injected). Also note a pacemaker lead in the coronary sinus. At an angle of 49°, the LVOT is on the right side, indicating dextrocardia. This view is typically obtained at 120–140° with levocardia – sort of a mirror image.

5.78. C. Dilated azygos vein.

This is a typical appearance. This patient had an interrupted IVC, and the IVC drained through the azygos vein into the superior vena cava. The IVC does not relate to the thoracic aorta. A mirror image artifact looks like a duplicate image of the DTA.

Box 5.1 Key Practical Pearls

- Higher transducer frequency results in better resolution, but reduced penetration. Better color flow images are obtained at lower transducer frequency.
- To increase frame rate, reduce depth or sector angle and eliminate color flow if you can. Reduce the color flow box width as narrow as possible to increase frame rate.
- Regurgitant jets are underestimated at low frame rates and low gain. Wall-hugging jets are smaller for a given severity because of loss of kinetic energy at the jet–wall interface. Jet size depends on kinetic energy contained in the jet, and hence is a function of both regurgitant flow rate and driving pressure.
- In AS assessment: zoom LVOT and clean up to see LVOT boundaries clearly, obtain V1 to minimize spectral dispersion and V2 from multiple window. For peak velocity of V1, get the peak but for TVI trace through modal velocity.
- In obtaining pressure half-time in MS, ignore the initial rapid ski slope, which is affected markedly by LV relaxation and recoil. Mean gradient depends on heart rate: lower at lower heart rate due to longer diastolic filling time. Mean gradient should be given along with heart rate.

- A TEE has a higher spatial resolution than a transthoracic echocardiogram because of higher carrier frequency.
- In the performance of TEE, get the key information first to answer the clinical question, just in case patient becomes intolerant of the procedure and the procedure needs to be abandoned. For example, when the question is rule out acute aortic dissection, examine ascending aorta first as its involvement mandates emergency ascending aortic repair. Then look at pericardial effusion, LV function, AR and its mechanism, extent of dissection, entry point location, coronary and arch vessel involvement, and so on. In suspected endocarditis, examine the left- and then right-sided valves first in a comprehensive fashion from midaortic location, which is most tolerable for the patient.

Box 5.2 Key Guideline Summaries

- Echocardiographic criteria for severe MR include jet area to LA area ratio >40%, jet area >10 cm^2, vena contracta diameter ≥7 mm, regurgitant volume ≥60 cm^3, regurgitant fraction ≥50%, ERO area ≥0.4 cm^2, or systolic flow reversal in any of the pulmonary veins. There may be a large coaptation defect in mitral valve closure mechanism. MR signal by continuous wave may be triangular, the so-called "V" wave cutoff sign due to large LA "V" wave. (Zoghbi *et al.*, 2003). In eccentric wall-hugging jets, jet size may be smaller by as much as 50% for a given regurgitant volume.
- Echocardiographic sign of severe MS is mitral valve area <1.0 cm^2 with or without supporting features of mean diastolic gradient of >10 mmHg or PA systolic pressure of >50 mmHg (Baumgartner *et al.*, 2009).
- Echocardiographic criteria for severe AS include aortic valve area <1.0 cm^2, indexed valve area <0.6 cm^2, V2 >4 m/s, mean gradient >40 mmHg, or velocity ratio (V1/V2) <0.25 (Baumgartner *et al.*, 2009).
- Severe AS with low gradient is said to exist when AV area <1 cm^2 and mean gradient <30 mmHg and can occur in those with both normal and low EF and is associated with high mortality which is reduced by AVR. Low-dose dobutamine echo can be used in these patients to differentiate from pseudo severe AS (increase in AV area with increase in cardiac output), true severe AS (mean gradient increases with increase in stroke volume, but AV area remains unchanged), or evaluate for contractile reserve (EF and cardiac output increase).
- Echocardiographic criteria for severe AR include jet height to LVOT diameter ratio ≥65%, jet area to LVOT area ≥60%, vena contracta diameter >6 mm, regurgitant volume ≥60 cm^3, regurgitant fraction ≥50%, ERO area ≥0.3 cm^2, or prominent holodiastolic flow reversal in descending aorta. AR pressure half-time may be <200 ms (Zoghbi *et al.*, 2003).
- Echocardiographic criteria for severe TR include jet area >10 cm^2, vena contracta diameter >7 mm, PISA radius >9 mm at a Nyquist limit of 50–60 cm/s, or systolic flow reversal in hepatic veins. There may be a large coaptation defect in tricuspid valve closure mechanism. TR signal by continuous wave may be triangular, the so called "V" wave cutoff sign due to large RA "V" wave (Zoghbi *et al.*, 2003).
- Criteria for severe tricuspid stenosis: mean diastolic gradient ≥5 mmHg, diastolic TVI >60 cm, pressure half-time ≥190 ms, tricuspid valve area by continuity equation ≤1.0 cm^2 (Baumgartner *et al.*, 2009).

- Echocardiographic criteria for severe PR include large jet size at origin, steep deceleration of PR signal by continuous wave often stopping in mid-diastole, increased pulmonary flow compared with systemic flow, and RV enlargement. Features are less quantitative (Zoghbi *et al*., 2003).
- Echocardiographic criteria for severe PS: peak systolic velocity >4 m/s or peak systolic gradient >64 mmHg (Baumgartner *et al*., 2009).

Box 5.3 Important Clinical Trial or Outcome Data Summaries

- **Cardiac resynchronization therapy (CRT) in narrow QRS cohort study.** In the Yu *et al.* (2006) study, of the 102 patients with class III or IV heart failure and EF <35%, 51 had QRSd <120 ms but had LV mechanical asynchrony by echo. Both groups had similar response to CRT in terms of 6 min walk test and reduction in LV volumes and MR and improvement in EF. Response rate in both groups was about 70%.
- **RethinQ trial.** In the Beshai *et al.* (2007), 172 patients with standard indication for ICD, QRSd <130 ms, and echocardiographic evidence of LV dyssynchrony were randomized to CRT versus no CRT. Primary endpoint was improvement in peak oxygen consumption. There was no improvement in peak oxygen consumption with CRT. Subgroup analysis showed improvement in those with QRSd >120 ms. The 6 min walk improved significantly in those with nonischemic cardiomyopathy and New York Heart Association class improved in both groups. The trial is criticized for poor echo data quality, three different core labs, lack of standardization, three different vendors, need to drop some data, and poor reproducibility.
- **Echo-CRT trial.** In the Ruschitzka *et al.* (2013) study, 809 patients with heart failure class III or IV, EF <35%, QRSd <130 ms, and echo evidence of LV dyssynchrony were randomized to ICD with CRT turned on or off. Of 1680, 809 patients had LV dyssynchrony. Primary endpoint was all-cause mortality and hospitalization for heart failure. The trial was stopped prematurely because of higher mortality in the CRT arm (hazard ratio 1.8, $p = 0.02$).

Cardiac Magnetic Resonance Imaging

6

6.1. Magnetic resonance imaging (MRI) makes use of nuclei with unpaired spins. What is the nucleus used in image production?

A. Hydrogen-1
B. Carbon-13
C. Phosphorus-31
D. Sodium-23

6.2. What is the resonance frequency with a 1.5 T scanner?

A. 63 MHz
B. 42 MHz
C. 126 MHz
D. None of the above

6.3. How is spatial localization of signal origin achieved?

A. Magnetic gradient
B. Timing of received RF signal
C. Timing of transmitted RF signal
D. All of the above

6.4. With which of the following is cardiac MRI generally not advisable in patients?

A. Automated implantable cardioverter defibrillator
B. Cerebral aneurysm clips
C. Iron-containing foreign body in the eye that has been there for 6 years
D. All of the above
E. None of the above

6.5. What are the potential effects of a strong magnetic field in a patient with a pacer or implantable cardioverter-defibrillator?

A. May burn the circuits
B. Heat generation at lead tip and tissue coagulation and rise in threshold
C. Reset device
D. All of the above

6.6. Gadolinium (Gd) does which of the following?

A. Shortens T1 and increases signal on T1-weighted images
B. Lengthens T1 and increases signal on T1-weighted images
C. Shortens T1 and reduces signal on T1-weighted images
D. Lengthens T1 and reduces signal on T1-weighted images

6.7. Which of the following can magnetic resonance (MR) coronary angiography be performed with?

A. Single breath hold
B. Multiple breath holds
C. With the use of a navigator pulse
D. None of the above

6.8. In the FIESTA or steady-state free precession (SSFP) MR image shown in Figure 6.8, what does "1" refer to?

A. Right ventricle
B. Left ventricle
C. Right atrium
D. Left atrium

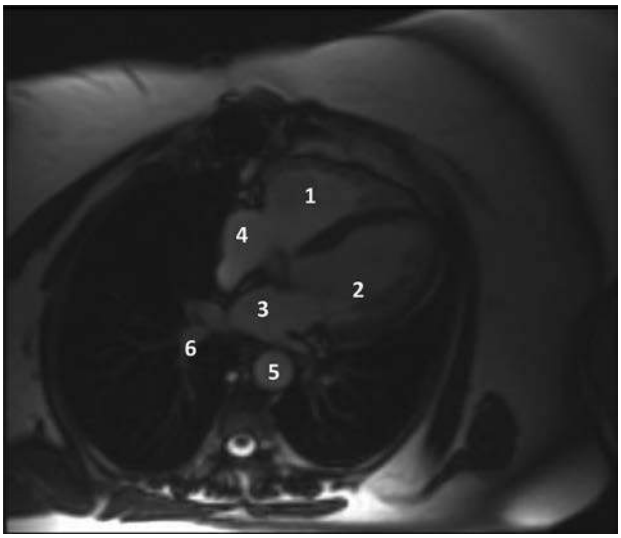

Figure 6.8

6.9. In the FIESTA or SSFP MR image shown in Figure 6.9, what does "2" refer to?

A. Right ventricle
B. Left ventricle
C. Right atrium
D. Left atrium

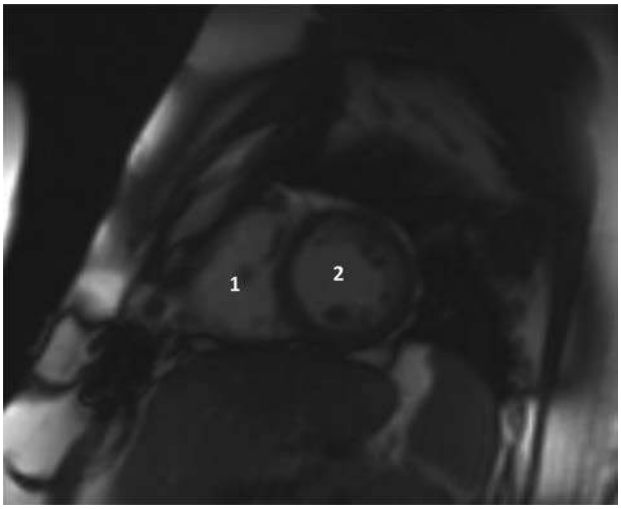

Figure 6.9

6.10. In the T1-weighted black blood MR image shown in Figure 6.10, what does "1" refer to?

A. Right ventricle
B. Left ventricle
C. Right atrium
D. Left atrium

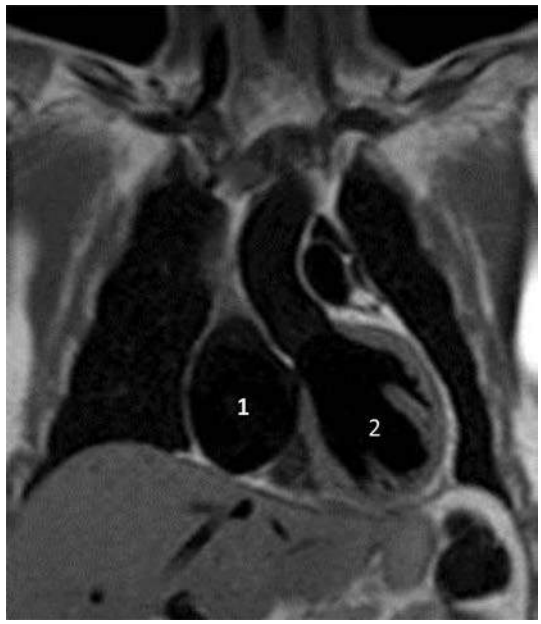

Figure 6.10

6.11. Figure 6.11 shows a delayed Gd-enhanced image in a patient with occluded left anterior descending (LAD) artery. What is the image indicative of?

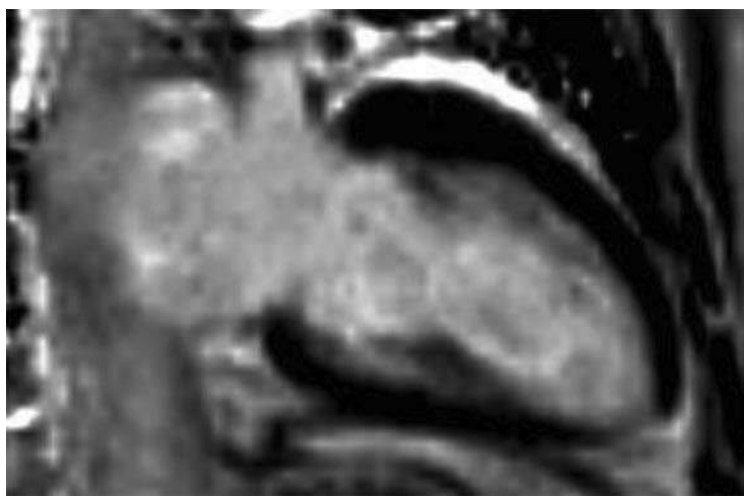

Figure 6.11

A. Scarred left ventricle anterior wall
B. Scarred left ventricle inferior wall
C. LAD area looks fully viable
D. None of the above

6.12. What does the MRA in Figure 6.12 show?
A. Pulmonary artery branch stenosis
B. Pulmonary infundibular stenosis
C. Normal pulmonary veins
D. None of the above

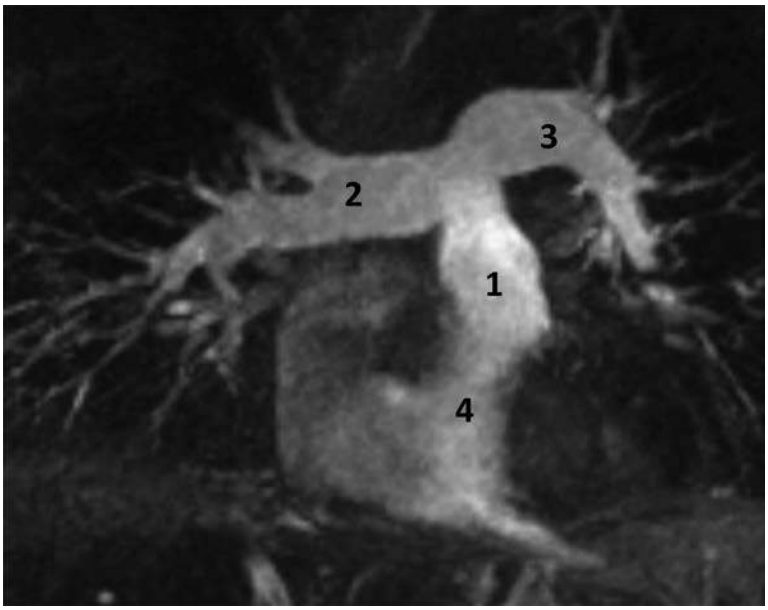

Figure 6.12

6.13. What does the image in Figure 6.13 show?
A. T1-weighted image
B. FIESTA image
C. Contrast-enhanced MRA
D. None of the above

6.14. Which of the following statements about Figure 6.14 are accurate?
A. It is a volume-rendered MRA image
B. Gd contrast was used for imaging
C. 1, 2, and 3 refer to ascending aorta, main pulmonary artery (MPA), and pulmonary veins respectively
D. All of the above

6.15. What does the arrow point to in Figure 6.15?
A. Lipomatous atrial septum
B. Atrial myxoma
C. Sarcoma
D. Artifact

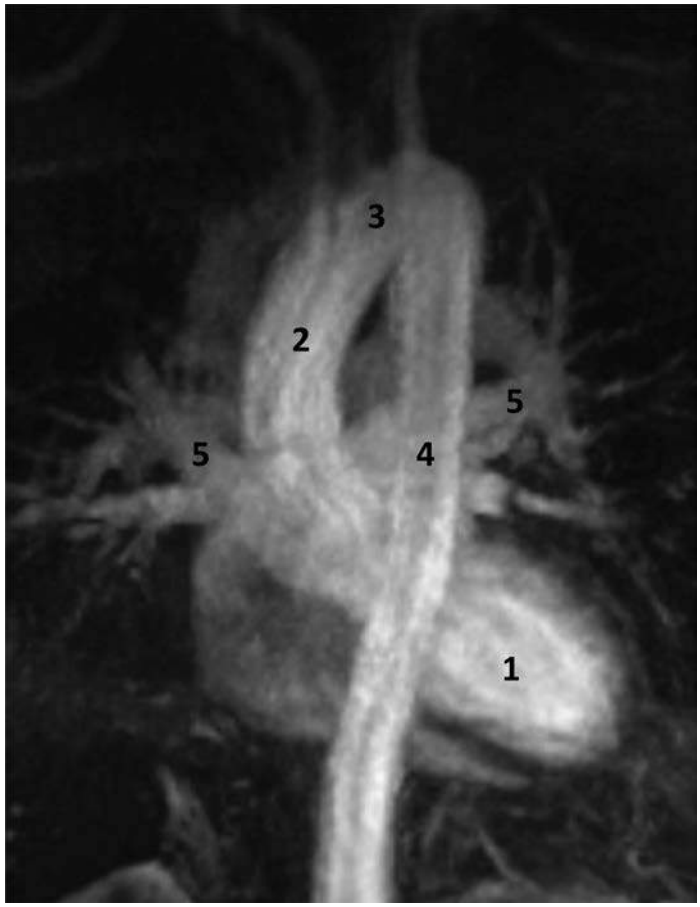

Figure 6.13

Figure 6.14

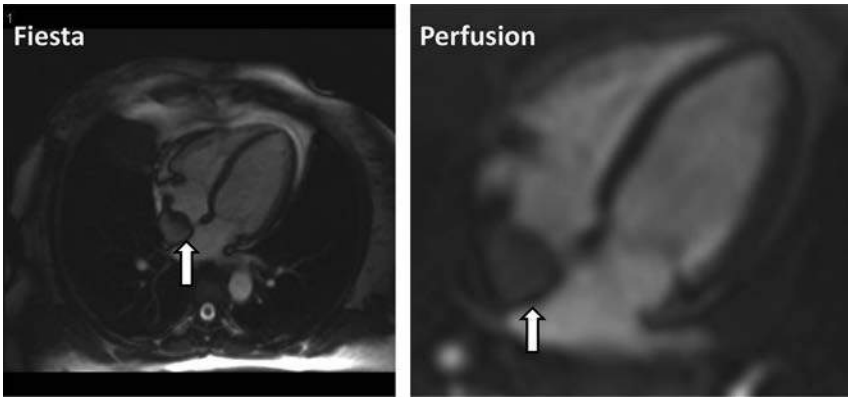

Figure 6.15

6.16. What is the patient in Figure 6.16 likely to have?

A. Heart failure
B. Pneumonia
C. Atrial septal defect
D. Descending aortic dissection

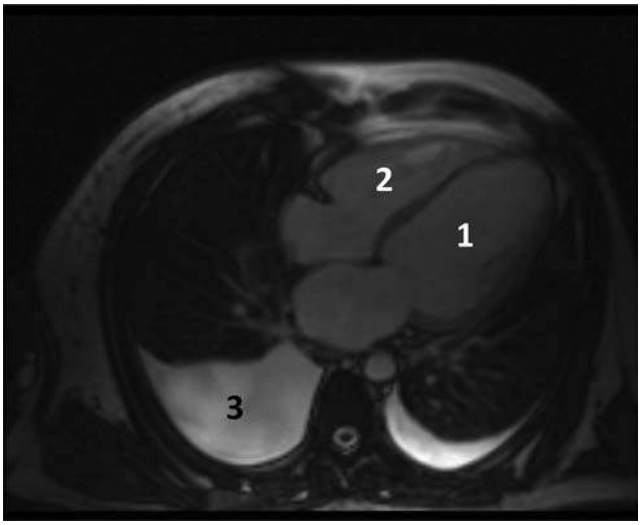

Figure 6.16

6.17. What is the patient in Figure 6.17 likely to have?

A. Multivessel coronary artery disease
B. Single-vessel circumflex disease
C. Extensive myocardial scarring due to prior infarcts
D. Normal coronary artery

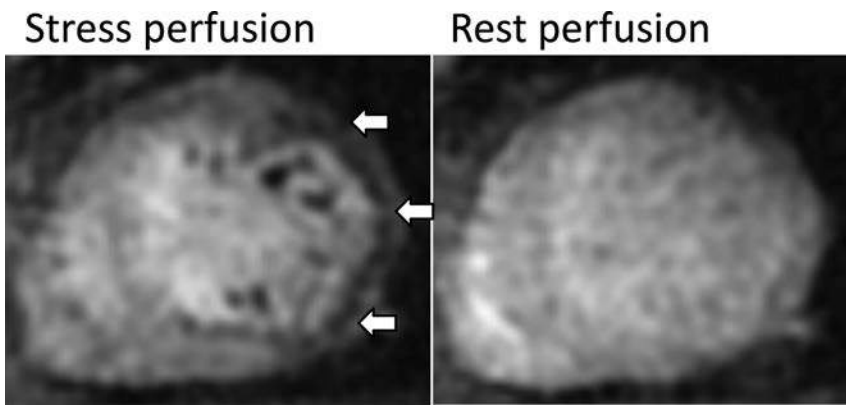

Figure 6.17

6.18. What is the patient in Figure 6.18 likely to have had?

A. Arrhythmogenic right ventricular dysplasia (ARVD)
B. Inferior myocardial infarction
C. Anterior myocardial infarction
D. Myocarditis

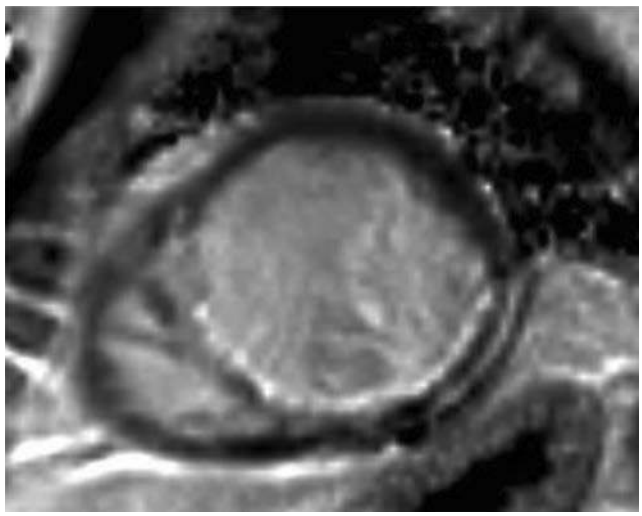

Figure 6.18

6.19. What is the patient in Figure 6.19 likely to have had?

A. ARVD
B. Inferior myocardial infarction
C. Anterior myocardial infarction
D. Myocarditis

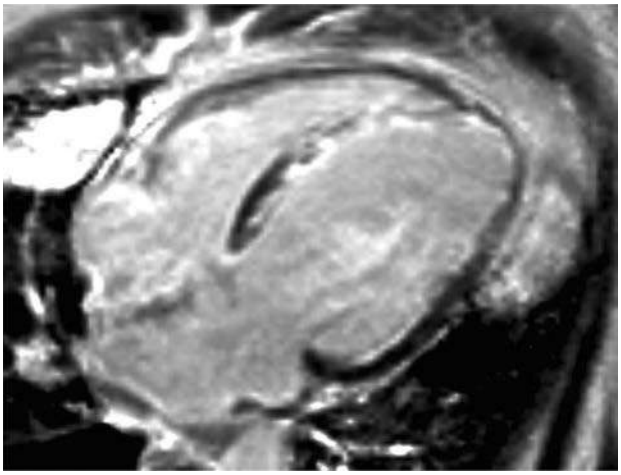

Figure 6.19

6.20. The patient in Figure 6.20 has severe left ventricle dysfunction. What is the etiology likely to be?

A. Left ventricle noncompaction
B. Myocarditis
C. Myocardial infarct with fatty replacement
D. Cardiac amyloid

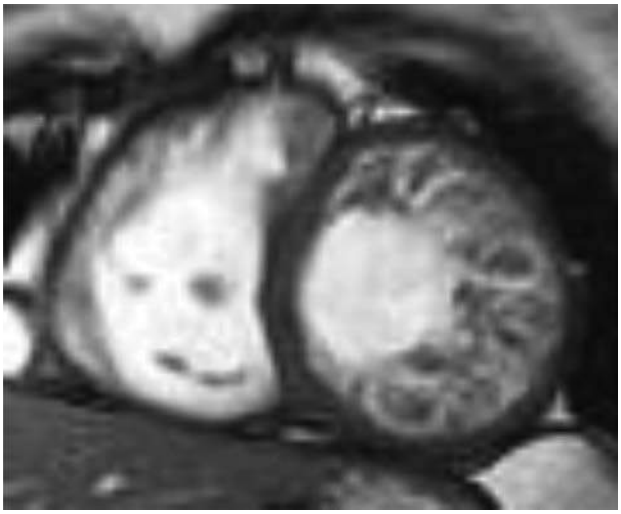

Figure 6.20

6.21. What is the patient in Figure 6.21 likely to have?

A. Bicuspid aortic stenosis
B. Aortic valve vegetation
C. Aortic dissection
D. None of the above

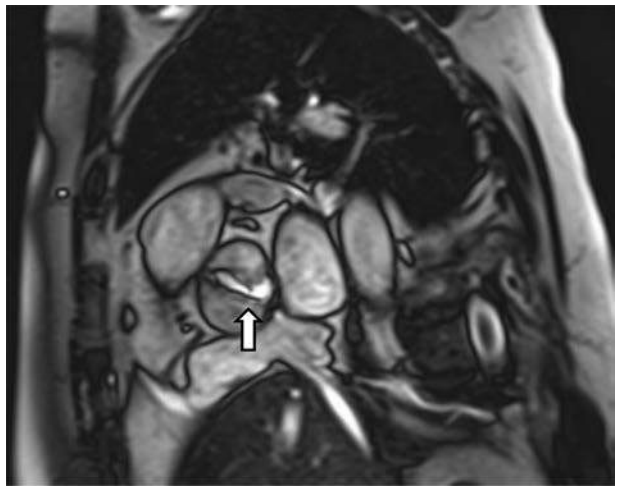

Figure 6.21

6.22. In the black blood cardiac MR image of the chest in Figure 6.22, what does the arrow point to?

A. Trachea
B. Right pulmonary artery
C. Left pulmonary artery
D. Aorta

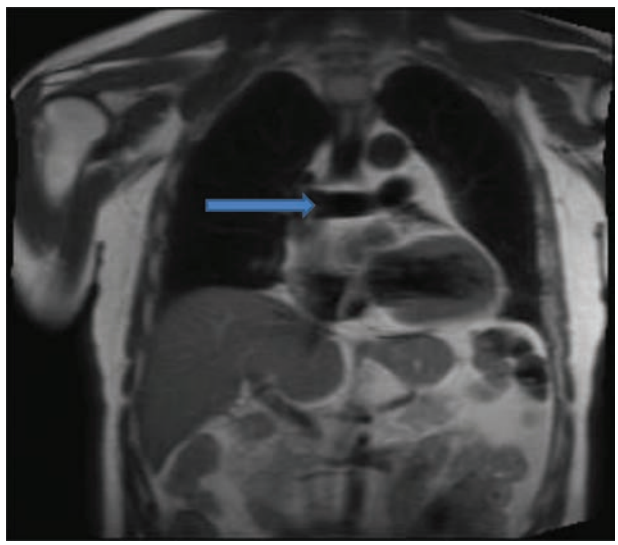

Figure 6.22

6.23. What structure does the arrow point to on the black blood cardiac MR image in Figure 6.23?

A. Trachea
B. Right main bronchus
C. Left main bronchus
D. Pulmonary artery

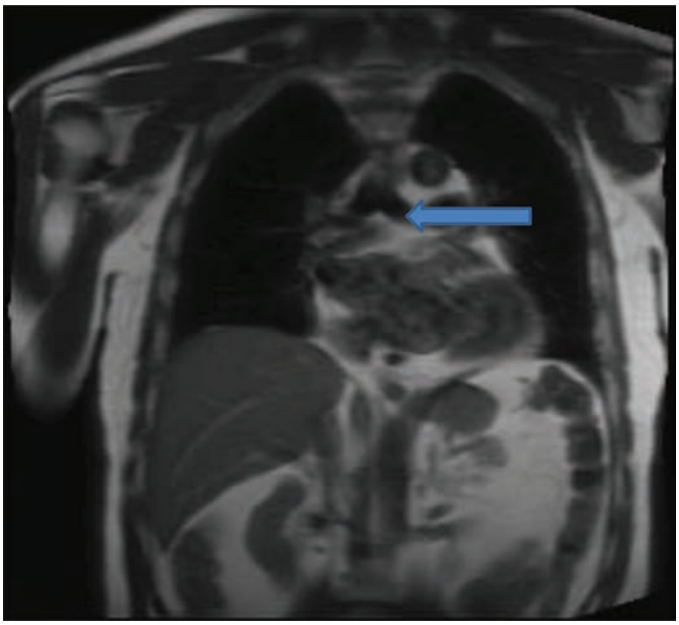

Figure 6.23

6.24. The 58-year-old male seen in Figure 6.24 complained of shortness of breath and palpitations (AO: aorta; LA: left atrium; LV: left ventricle). This patient probably has which of the following conditions?

A. Hypertrophic cardiomyopathy
B. Sigmoid shaped septum
C. Normal myocardium
D. Hypertensive heart disease

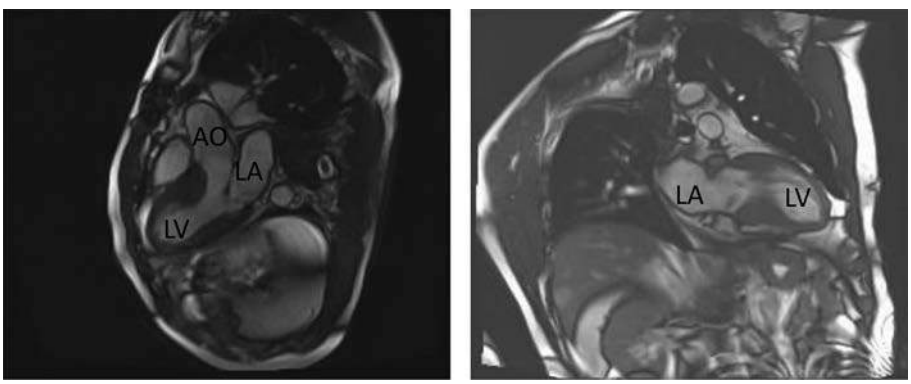

Figure 6.24

6.25. The regions arrowed in the inversion recovery images from the patient in Question 6.24 shown in Figure 6.25 are indicative of what? (LA: left atrium; LV: left ventricle; RA: right atrium; RV: right ventricle)

A. Normal myocardium
B. Transmural LGE of the septum
C. Subendocardial LGE of the septum and lateral wall
D. Midmyocardial patchy LGE of the septum and inferolateral wall

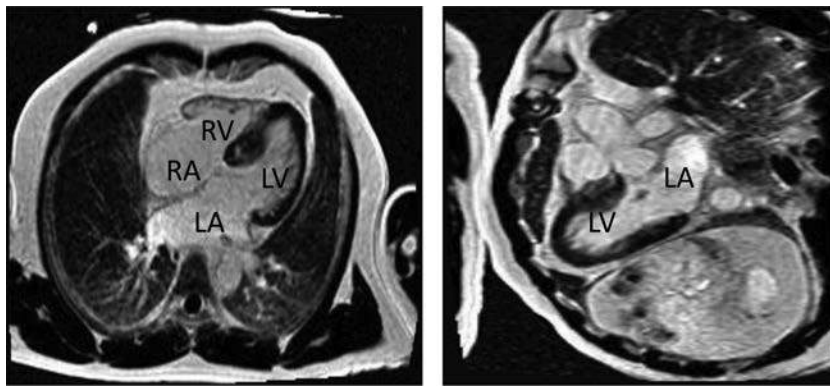

Figure 6.25

6.26. What does the still frame of the short-axis image in Figure 6.26a show?

A. Cleft anterior mitral valve
B. Cleft posterior mitral valve
C. Normal mitral valve
D. Mitral valve vegetation

6.27. What structure does the arrow point to on the bright blood cardiac MR image in Figure 6.27a?

A. Main pulmonary artery
B. Ascending aorta
C. Right pulmonary artery
D. Left pulmonary artery

6.28. What structure does the arrow point to on the bright blood cardiac MR image shown in Figure 6.28a?

A. Main pulmonary artery
B. Ascending aorta
C. Right pulmonary artery
D. Left pulmonary artery
E. Descending aorta

6.29. What structure does the arrow point to in the bright blood cardiac MR image in Figure 6.29a?

A. Superior vena cava
B. Inferior vena cava
C. Pulmonary artery
D. Aorta

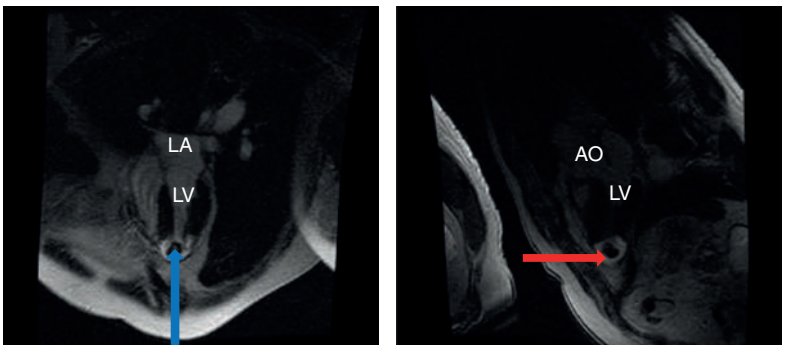
6.30. A 50-year-old male was admitted to hospital with complaints of chest pain. The electrocardiogram obtained at the time of admission showed 3 mm ST elevation in leads V3–V6. He was rushed to the cardiac cath lab, which showed occlusion of the distal LAD artery. He then underwent cardiac MRI to evaluate left ventricle function and scar burden. What do the inversion recovery images in Figure 6.30 show?

A. LGE of the left ventricular apex
B. Transmural LGE of the apex with an apical thrombus
C. Apical thrombus
D. Subendocardial LGE of the apex



LA: left atrium; LV: left ventricle; AO: aorta

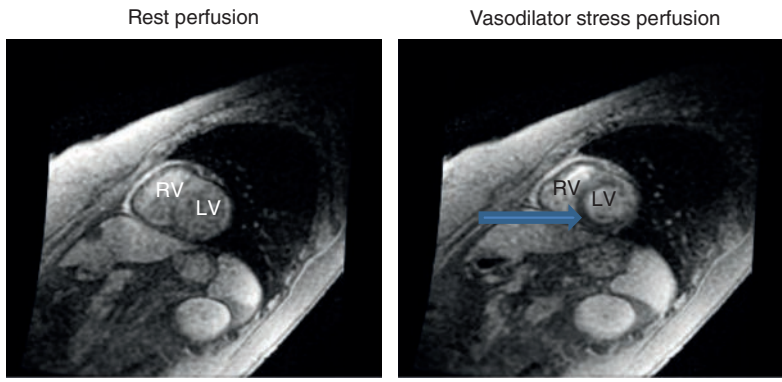
Figure 6.30

6.31. An 18-year-old female with a history of hypertension underwent a procedure. Based on the images shown in Figure 6.31, what procedure did she undergo?
A. Aortoplasty
B. Balloon dilatation of aorta
C. Stent of coarctation of the aorta with restenosis
D. Surgical anastomosis of coarctation of aorta with restenosis

Figure 6.31

6.32. A 50-year-old female patient is referred to the cardiology clinic for complaints of substernal chest pain. She has complaints of palpitations, and a Holter monitor demonstrated premature ventricular complexes. Her family history is significant for premature coronary artery disease. Owing to orthopedic problems, she underwent a Lexiscan stress cardiac MRI. What do the perfusion images in Figure 6.32 show?

A. Stress-induced myocardial perfusion defect in the septum, anterior and inferior walls
B. Rest myocardial perfusion defect in the anterior and inferior walls
C. Global stress-induced perfusion defect
D. Artifact



RV: right ventricle; LV: left ventricle

Figure 6.32

6.33. What do the contrast-enhanced MRA and volume-rendered image of the aorta in Figure 6.33 show?

A. Normal aorta
B. Dissection in the ascending aorta
C. Dissection flap in the descending aorta start just distal to the arch
D. Artifact

6.34. A 58-year-old male patient was admitted to hospital for chest pain. He has a history of hypertension and chronic smoking and his echo images were suboptimal. He underwent a cardiac MRI (Figure 6.34) to evaluate left ventricle function. What is the cause of his chest pain?

A. Myocarditis
B. Constrictive pericarditis
C. Dissection of the aorta
D. Pulmonary embolism

6.35. What does the still-frame long-axis view of the heart in Figure 6.35 show?

A. Normal aortic and mitral valves
B. Normal aortic valve
C. Normal mitral valve and artifact from a prosthetic aortic valve
D. None of the above

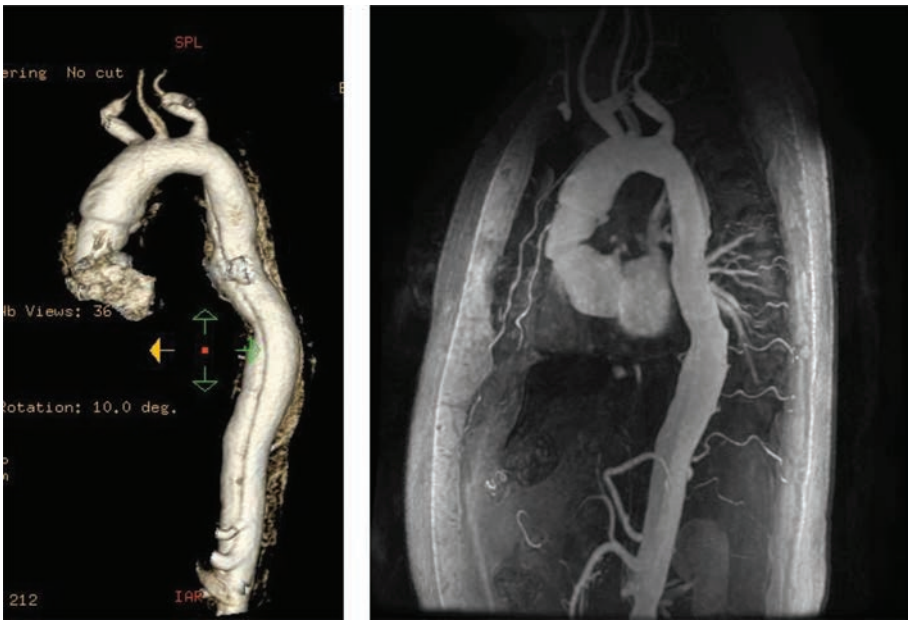


Figure 6.33

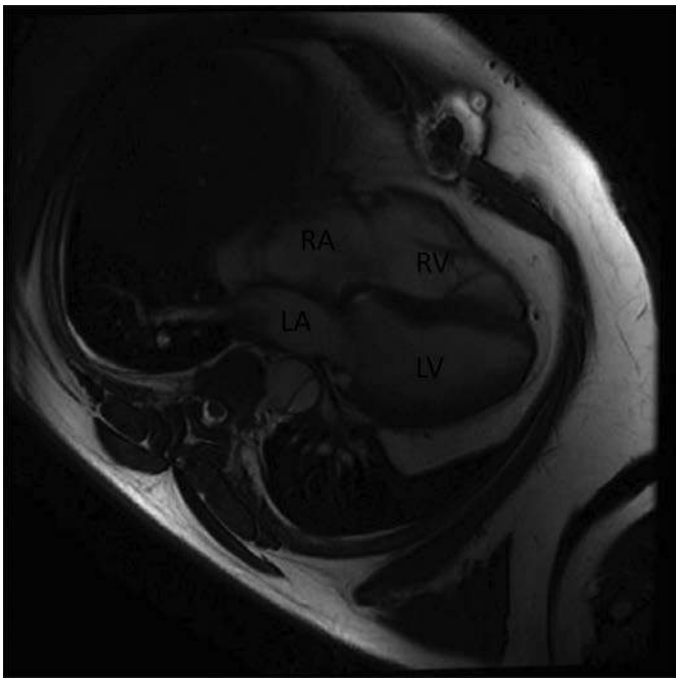

Figure 6.34

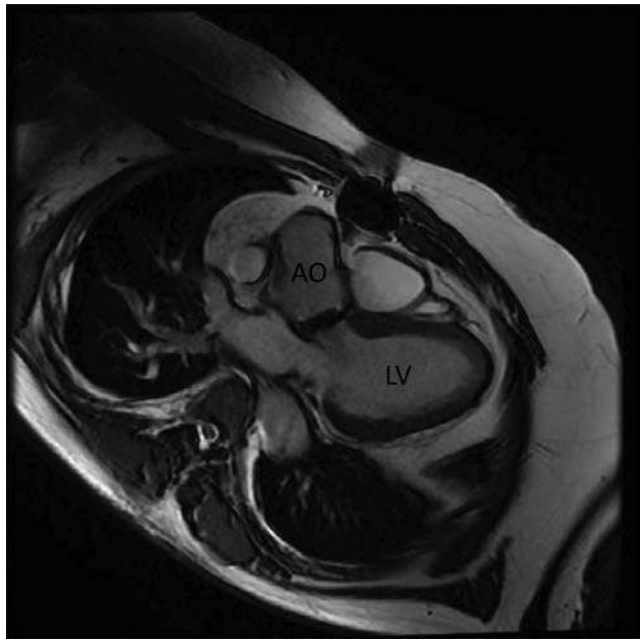

Figure 6.35

6.36. A 50-year-old female had a routine transthoracic echocardiogram. Her cardiologist found a mass in the right atrium. She was then referred for a cardiac MRI (see Figure 6.36) to evaluate this mass further. What is the mass is suggestive of?

A. Right atrial myxoma
B. Right atrial sarcoma
C. Thrombus
D. Lipomatous hypertrophy of the interatrial septum

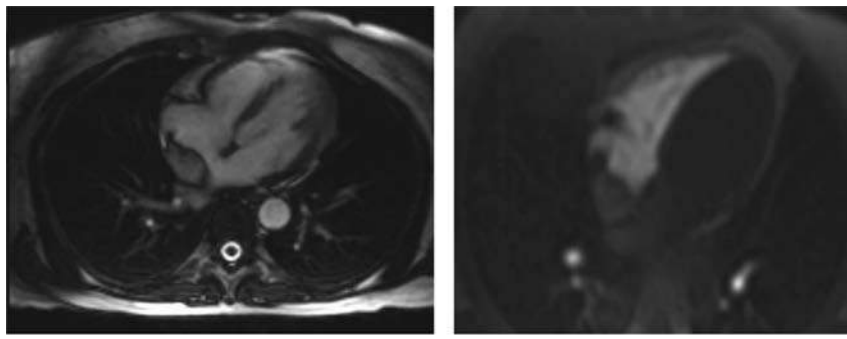

Figure 6.36

Answers

6.1. A. Hydrogen-1.
Hydrogen-1 is most abundant in living tissues.

6.2. A. 63 MHz.
It is 42 MHz multiplied by the magnetic field strength B_o in tesla.

6.3. A. Magnetic gradient.
There is a slight gradient in *X*, *Y*, and *Z* planes (strength of magnetic field varies from slightly above to below 1.5 T in a 1.5 T system) and this helps localize where the signal is coming from.

6.4. D. All of the above.
Spinal cord stimulator is a contraindication as well. Coronary stents, heart valves, artificial joints, and vertebral plates are not contraindications.

6.5. D. All of the above.

6.6. A. Shortens T1 and increases signal on T1-weighted images.
The seven unpaired electrons on Gd couple with excited water spins and hasten relaxation, thereby reducing T1. This property of Gd is used for magnetic resonance angiography (MRA), first-pass perfusion, and late Gd enhancement (LGE) of myocardial scar.

6.7. C. With the use of a navigator pulse.
It takes 15–20 min based on slice thickness and extent needed and hence needs navigator pulse to track the diaphragm so that images can be acquired only at certain phases of the respiratory cycle.

6.8. A. Right ventricle.
The other numbers indicate the following structures: 2, left ventricle; 3, left atrium; 4, right atrium; 5, descending thoracic aorta; 6, pulmonary vein.

6.9. B. Left ventricle.
Structure "1" is the right ventricle.

6.10. C. Right atrium.
Structure "2" is the left ventricle. This is the coronal plane.

6.11. C. LAD area looks fully viable.
The scar looks white on delayed Gd-enhanced imaging. There is no evidence scarring in this image.

6.12. D. None of the above.
This is a normal MRA of the pulmonary artery and branches: 1, main pulmonary artery; 2, right pulmonary artery; 3, left pulmonary artery; 4, right ventricle outflow tract.

6.13. C. Contrast-enhanced MRA.
This is of the aorta. The aorta looks normal. 1, left ventricle; 2–4, aorta; 5, pulmonary veins.

6.14. D. All of the above.

6.15. A. Lipomatous atrial septum.
Its location in the atrial septum and the absence of a perfusion point to a lipomatous septum. There was no delayed enhancement.

6.16. A. Heart failure.

Note the bilateral pleural effusions. The left ventricle seems to be dilated with thinning of the apical area. The atrial septum is intact and bowing to the right, indicating high right atrial pressure. The descending aorta (behind left atrium) is normal (1: left ventricle; 2: right ventricle; 3: left pleural effusion).

6.17. A. Multivessel coronary artery disease.

The dark area pointed by the arrows is a perfusion defect during first-pass perfusion using Gd chelate. The perfusion defect is seen during vasodilator stress in the lateral wall as well as anterior and inferior walls and completely fills in during rest perfusion. Reversible perfusion defect indicates ischemia and not infarct, and extent indicates multivessel disease.

6.18. B. Inferior myocardial infarction.

Subendocardial scar indicates an infarct; involvement of inferior septum and inferior wall is consistent with right coronary artery lesion. In ARVD, scarring may be seen in the right ventricle wall along with fatty deposit, dilation, aneurysm formation, and reduced function. Scar pattern in myocarditis may be patchy, midmyocardial, subepicardial, or even transmural.

6.19. C. Anterior myocardial infarction.

Note the scar distribution in mid and distal septum consistent with LAD artery lesion.

6.20. A. Left ventricle noncompaction.

Note the heavily trabeculated left ventricle with noncompated to compacted myocardial thickness ratio of >2.5. There is a high risk of thrombus formation, and anticoagulation is recommended when there is a thrombus, embolic event, atrial fibrillation, or just EF is <40%. In cardiac amyloid, left ventricle would be thick.

6.21. A. Bicuspid aortic stenosis.

The arrow in Figure 6.21 is pointing to the aortic valve. This is a FIESTA or SSFP cine sequence.

6.22. B. Right pulmonary artery.

6.23. C. Left main bronchus.

The arrow in Figure 6.23 is pointing to the left main bronchus. The carina is shown well where the trachea branches into the right and left main bronchi.

6.24. Hypertrophic cardiomyopathy.

This patient has hypertrophy of his anterior septum and anterior and inferior walls. The upper septum is asymmetrically hypertrophied (arrow) and points more to hypertrophic cardiomyopathy.

6.25. D. Midmyocardial patchy LGE of the septum and inferolateral wall.

The LGE pattern seen here is midmyocardial patchy enhancement, whereas in the setting of coronary artery disease the LGE pattern is either subendocardial or transmural.

6.26. A. Cleft anterior mitral valve.

The short-axis mitral valve view shows a cleft of the anterior mitral valve (arrowed in Figure 6.26b).

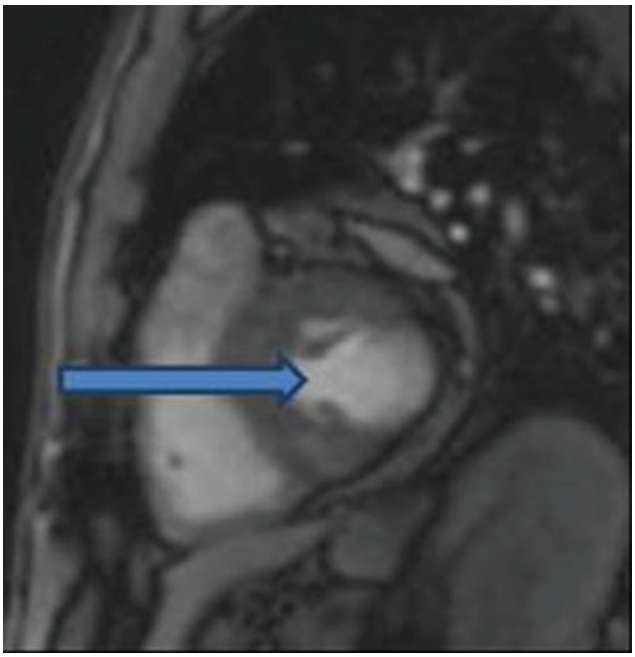

Figure 6.26b

6.27. A. Main pulmonary artery.

Figure 6.27b shows the main pulmonary artery (MPA), along with the aorta (AO).

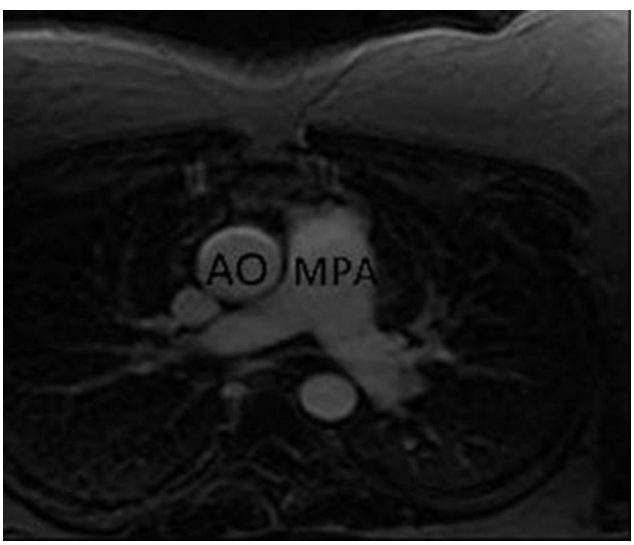

Figure 6.27b

6.28. E. Descending aorta.

Figure 6.28b shows the descending aorta (arrowed), along with the aorta (AO) and main pulmonary artery (MPA).

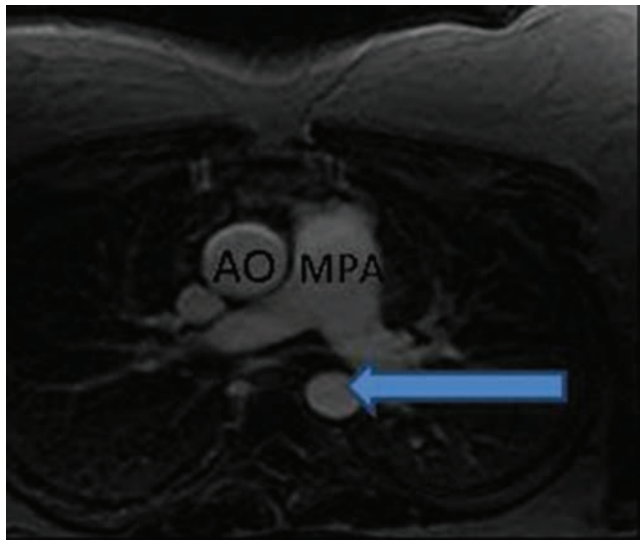

Figure 6.28b

6.29. A. Superior vena cava.

Figure 6.29b shows the superior vena cava (SVC), along with the right atrium (RA).

6.30. B. Transmural LGE of the apex with an apical thrombus.

The red arrow in Figure 6.30 shows transmural LGE of the apex and the blue arrow an apical thrombus. Both the four- and three-chamber views show transmural scar of the apex with a dark filling defect representing thrombus. The scarred areas take up Gd that is not washed out and appears as bright areas on this sequence, whereas thrombus does not take up contrast and appears as a filling defect (LV: left ventricle; LA: left atrium; AO: aorta).

6.31. C. Stent of coarctation of the aorta with restenosis.

The stented segment, which measured 30 mm, is clearly seen on both images in Figure 6.31. The lumen of the stented segment is narrowed up to 50%, representing restenosis.

6.32. A. Stress-induced myocardial perfusion defect in the septum, anterior and inferior walls.

The arrow in Figure 6.32 shows the stress-induced perfusion defect in the septum, anterior and inferior walls (LV: left ventricle). At rest there is homogeneous perfusion of Gd in all myocardial segments. With vasodilator stress there is lack of perfusion in the septum, anterior and inferior walls (dark areas), representing myocardial ischemia.

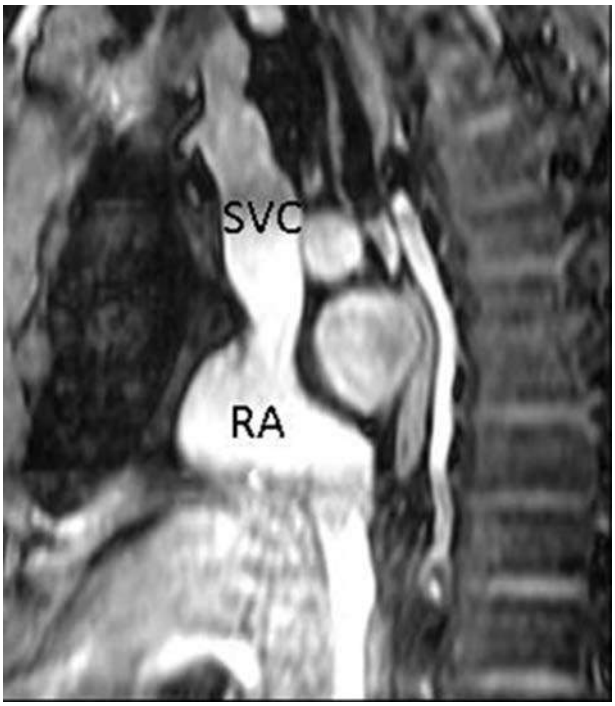

Figure 6.29b

6.33. C. Dissection flap in the descending aorta start just distal to the arch.

The contrast-enhanced image of the aorta shows contrast in the true lumen (T), while the false lumen (F) does not enhance. The blue arrow points to the dissection flap. This patient had a type A dissection and underwent ascending aortic repair including a hemiarch.

6.34. C. Dissection of the aorta.

The size of the heart looks normal. Figure 6.34, a still-frame image, shows a flap in the descending aorta (arrow; LA: left atrium; LV: left ventricle; RA: right atrium; RV: right ventricle). The cause of this patient's chest pain is due to dissection of the aorta.

6.35. C. Normal mitral valve and artifact from a prosthetic aortic valve.

This patient has a normal mitral valve but has a prosthetic aortic valve. There is artifact from the mechanical prosthesis indicative of a mechanical aortic valve (arrow; LV: left ventricle; LA: left atrium; AO: aorta).

6.36. D. Lipomatous hypertrophy of the interatrial septum.

The mass is lipomatous hypertrophy of the interatrial septum. The mass is in continuity with the upper part of the interatrial septum. On the perfusion image there is no enhancement indicative of avascularity. On T1-weighted images this mass will appear bright and can be suppressed with fat suppression sequences (LV: left ventricle; RV: right ventricle; RA: right atrium).

Cardiac Computed Tomography

7

7.1. Which of the following scan modes is used for coronary calcium scanning?
- **A.** Prospective gated noncontrast
- **B.** Prospective gated contrast scan
- **C.** Retrospective gated noncontrast
- **D.** Retrospective gated contrast scan

7.2. What is the traditional slice thickness for coronary calcium screening?
- **A.** 0.625 mm
- **B.** 1 mm
- **C.** 3 mm
- **D.** 5 mm

7.3. Which scan mode is used for assessment of left ventricle function?
- **A.** Prospective, gated with contrast
- **B.** Retrospective, gated with contrast
- **C.** Retrospective, gated without contrast
- **D.** Prospective, gated without contrast

7.4. Which of the following imaging procedures is likely to be associated with lowest radiation exposure?
- **A.** Prospectively gated, electrocardiogram (ECG)-triggered cardiac computed tomography angiography (CTA)
- **B.** Retrospectively gated, cardiac CTA
- **C.** Coronary angiography
- **D.** Stress perfusion scan with sestamibi

7.5. Which of the following imaging procedures is likely to be associated with the highest radiation exposure?
- **A.** Retrospectively gated, cardiac CTA with dose modulation
- **B.** Retrospectively gated, cardiac CTA
- **C.** Dual-isotope myocardial perfusion scan with thallium and sestamibi
- **D.** Stress perfusion scan with sestamibi

7.6. Who are at the highest cancer risk with cardiac computed tomography (CT)?
- **A.** Men
- **B.** Women
- **C.** Blacks
- **D.** Caucasians

7.7. During cardiac CTA, which organ gets the highest radiation dose?
- **A.** Heart
- **B.** Lungs
- **C.** Esophagus
- **D.** Breast

Cardiology Board Review, First Edition. Ramdas G. Pai, Padmini Varadarajan and Sudha M. Pai.
© 2018 John Wiley & Sons, Ltd. Published 2018 by John Wiley & Sons, Ltd.

7.8. Which of the following affects radiation dose?
- **A.** Tube voltage
- **B.** Tube current
- **C.** Pitch
- **D.** All of the above

7.9. Pitch is table movement divided by collimated beam width. At a pitch of 1, there is no overlap of data. At a pitch >1 there is a gap, and with a pitch <1 there is overlap. Which pitch is likely to be associated with least amount of radiation?
- **A.** 0.4
- **B.** 0.6
- **C.** 1.0
- **D.** 3.0

7.10. Which one has least amount of radiation?
- **A.** Calcium score with electron-beam CT
- **B.** Calcium score with X-ray CT
- **C.** Chest X-ray
- **D.** Cardiac MRI with gadolinium vasodilator stress

7.11. Which of the following 45-year-old patients presenting to the emergency room (ER) with atypical chest pain are appropriate candidates for coronary CTA?
- **A.** Patient with hypertension, diabetes mellitus, and prior left anterior descending (LAD) artery stent
- **B.** Patient with hypertension, ECG shows nonspecific ST–T changes, negative cardiac enzymes
- **C.** Patient with a prior myocardial infarction followed by coronary artery bypass grafting
- **D.** All of the above

7.12. Which of the following agents are appropriate to slow the heart rate for coronary CTA?
- **A.** Beta blockers
- **B.** Nondihydropyridine calcium channel blocker (e.g., diltiazem)
- **C.** Ivabradine
- **D.** All of the above

7.13. Which of the following is likely to reduce radiation dose the most?
- **A.** Increasing pitch by 25%
- **B.** Decreasing tube current by 25%
- **C.** Decreasing tube current by 25%
- **D.** They are all similar

7.14. Which of the following is the best measure of radiation dose to the patient?
- **A.** CT dose index (CTDI)
- **B.** Dose–length product (DLP)
- **C.** Effective radiation dose (ERD)
- **D.** All of the above

7.15. What is the US legal limit for radiation dose to a pregnant woman for the entire length of pregnancy?
- **A.** 0.05 mSv
- **B.** 0.5 mSv
- **C.** 5 mSv
- **D.** 50 mSv

7.16. During coronary CTA to the mother, how much radiation is the fetus likely to get?
- **A.** 14 mSv
- **B.** 1.4 mSv
- **C.** 0.14 mSv
- **D.** None with shielding

7.17. What is the typical HU value for fat?
- **A.** −1000 HU
- **B.** −50 HU
- **C.** 0 HU
- **D.** 1000 HU

7.18. What is the typical HU threshold for calcium for calcium score is?
- **A.** 100
- **B.** 130
- **C.** 0
- **D.** 400

7.19. Image noise can be reduced by which of the following?
- **A.** Increasing tube voltage
- **B.** Increasing tube current
- **C.** Iterative reconstruction
- **D.** All of the above

7.20. Which of the following statements is correct about iterative reconstruction?
- **A.** It takes longer as it makes multiples passes through the data
- **B.** It increases signal-to-noise ratio
- **C.** It can be performed on any CT scanner
- **D.** All of the above

7.21. What is the image pixel size of a CT image reconstruction with a field of view (FOV) of 256 mm and a 512 × 512 matrix?
- **A.** 0.5 mm × 0.5 mm
- **B.** 0.25 mm × 0.25 mm
- **C.** 2 mm × 2 mm
- **D.** None of the above

7.22. How can the image pixel size be increased during CT image reconstruction?
- **A.** Decreasing FOV
- **B.** Increasing matrix
- **C.** Both
- **D.** Neither

7.23. Spatial and temporal resolution are affected by all of the following except which?
- **A.** Detector width
- **B.** Rotation time
- **C.** Dual-source technology
- **D.** Number of detector rows

7.24. If a reconstructed image is noisy, how can this noise be reduced?
- **A.** Increasing slice thickness
- **B.** Reducing slice thickness
- **C.** Changing window level
- **D.** None of the above

7.25. Which of the following techniques may be helpful for better coronary visualization for those with calcification?
- **A.** Dual-energy CT
- **B.** Reconstruction with sharp filter
- **C.** Both
- **D.** Neither

7.26. How can visualization within a stent be facilitated?
- **A.** Dual-energy CT
- **B.** Reconstruction with sharp filter
- **C.** Wide window
- **D.** Thin slice
- **E.** All of the above

7.27. In a person presenting to the ER with chest pain and suspicion of acute coronary syndrome (ACS), which of the following are appropriate indications for coronary CTA?
- **A.** Normal ECG and biomarkers, low or intermediate probability of CAD
- **B.** Nonspecific ECG changes and normal biomarkers, low or intermediate probability of CAD
- **C.** Nondiagnostic ECG and biomarkers, low or intermediate probability of CAD
- **D.** Normal ECG and biomarkers, low or intermediate probability of CAD, unable to exercise
- **E.** All of the above

7.28. In a person presenting to the ER with chest pain, negative ECG and enzymes, and a history of prior coronary stent, which of the following are appropriate or possibly appropriate indications for coronary CTA?
- **A.** Left main coronary artery drug-eluting stent, 4 mm, 1 year ago
- **B.** LAD coronary artery stent 2 years ago 2.5 mm
- **C.** Mid right coronary artery (RCA) stent, 3.5 mm a year ago
- **D.** All of the above

7.29. It is appropriate to perform coronary CTA in which of the following *asymptomatic* patients?
- **A.** Left main coronary artery stenting with stent size ≥3 mm
- **B.** Left main coronary artery stenting with stent size <3 mm
- **C.** LAD bifurcation stent 4 mm size
- **D.** None of the above

7.30. Which of the following are reasonable indications for coronary CTA?
- **A.** Patient with ejection fraction of 30%, low to intermediate risk for CAD, to rule out ischemic etiology
- **B.** To rule out anomalous origin or coronary artery
- **C.** To monitor for CAD post heart transplant
- **D.** To check for graft patency in a patient with chest pain after prior coronary artery bypass grafting
- **E.** All of the above

7.31. Which of the following does the arrow in Figure 7.31 point to?
- **A.** Anomalous RCA
- **B.** Normal RCA origin, not calcified
- **C.** Normal RCA origin, calcified
- **D.** None of the above

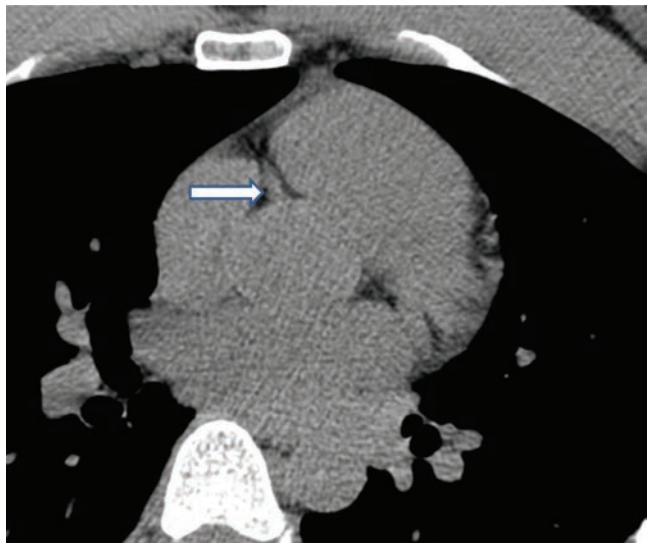

Figure 7.31

7.32. What is the arrow in Figure 7.32 pointing to?

A. Anomalous origin of left coronary artery
B. Normal left main coronary artery origin, not calcified
C. Normal left main coronary artery origin, calcified
D. Anomalous origin of RCA

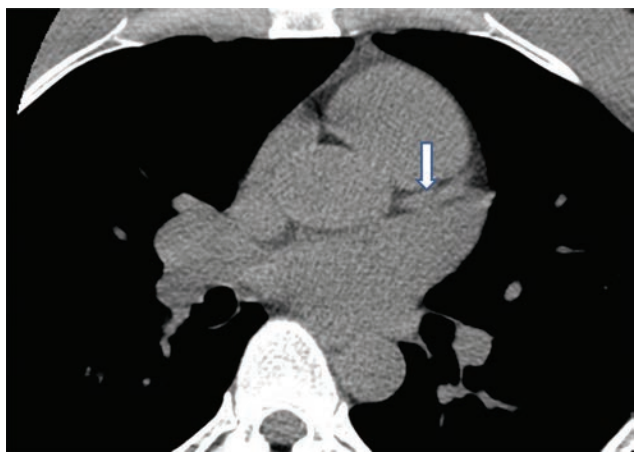

Figure 7.32

7.33. What do the numbers 1, 2, 3, and 4 correspond to in Figure 7.33?

A. Pulmonary veins: left upper, left lower, right upper, right lower respectively
B. Pulmonary veins: LEFT lower, left upper, right lower, right upper respectively
C. Pulmonary veins: right upper, right lower, left upper, left lower respectively
D. None of the above

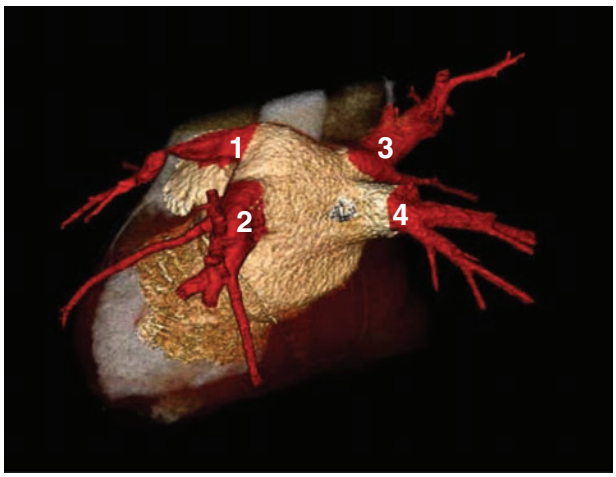

Figure 7.33

7.34. What does the number 1 correspond to in Figure 7.34?

A. Left atrial appendage
B. Left superior pulmonary vein
C. Left inferior pulmonary vein
D. Body of left atrium

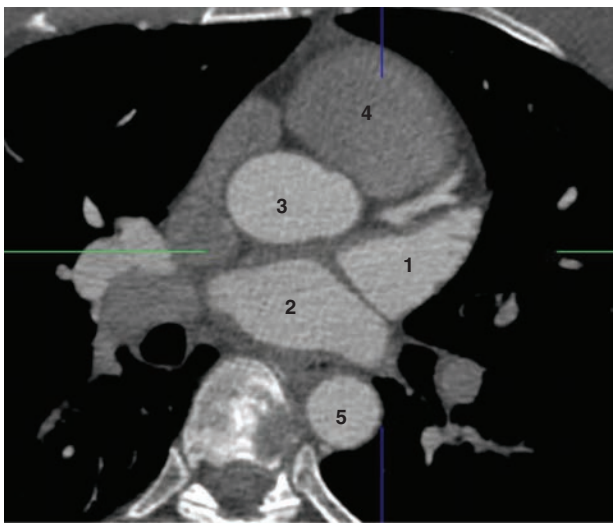

Figure 7.34

7.35. Figure 7.35 shows a volume rendered image viewed from the top. What does the number 1 refer to?

A. Ascending aorta
B. Pulmonary artery
C. Pulmonary vein
D. Body of left atrium

7.36. Figure 7.36 shows a volume rendered image. What does the number 1 refer to?

A. LAD artery
B. Diagonal artery
C. Circumflex artery
D. RCA

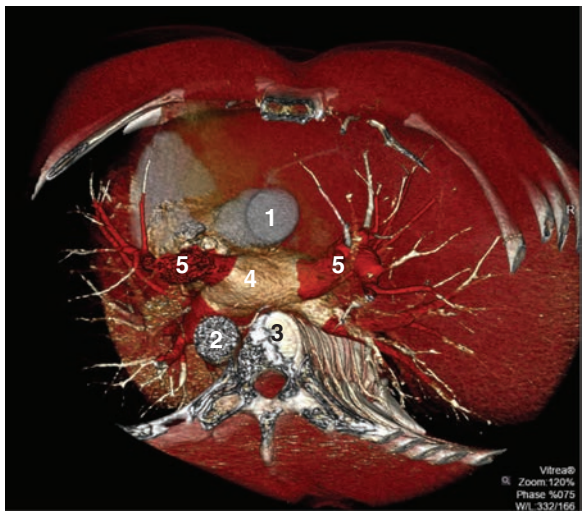

Figure 7.35

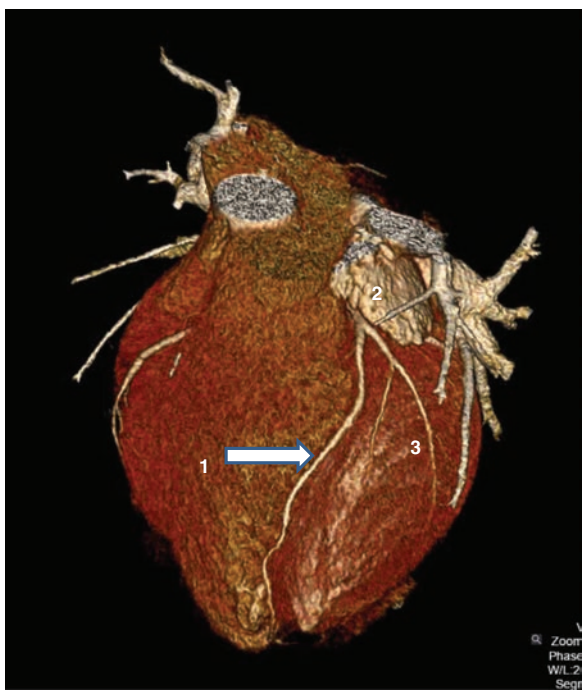

Figure 7.36

7.37. Figure 7.37 shows a volume rendered image. What does the arrow point to?

- **A.** LAD artery
- **B.** Diagonal artery
- **C.** Circumflex artery
- **D.** Right ventricle branch of RCA

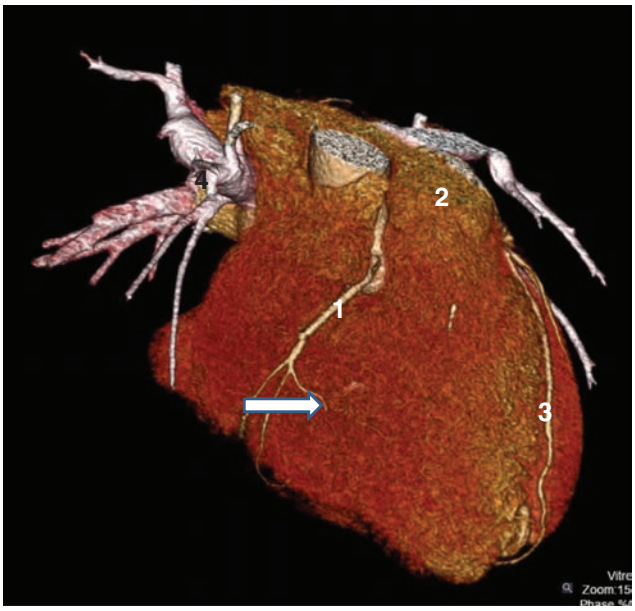

Figure 7.37

7.38. In Figure 7.38, what does the number 1 refer to?

A. RCA
B. Circumflex
C. Mitral annular calcification
D. Pericardiophrenic bundle

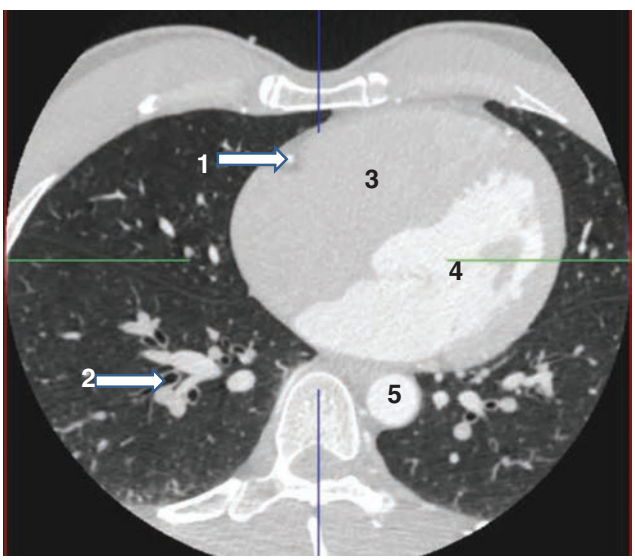

Figure 7.38

7.39. In Figure 7.39, what does the number 2 refer to?

A. Ascending thoracic aorta
B. Descending aorta
C. Inferior vena cava
D. Azygos vein

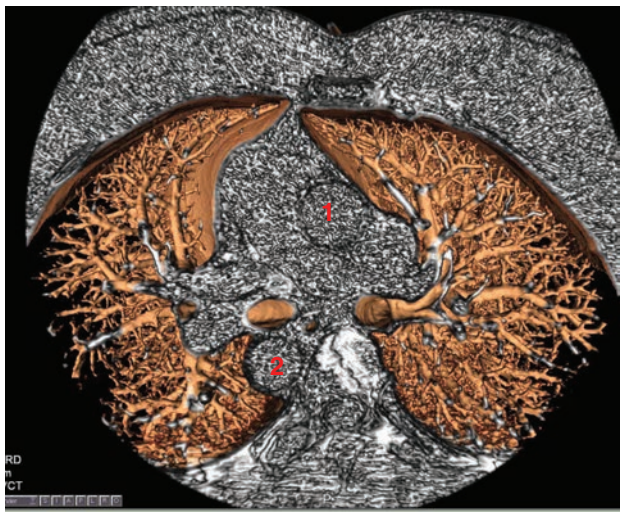

Figure 7.39

7.40. Figure 7.40 shows a volume rendered image. What does the number 1 refer to?

A. Left lower pulmonary vein
B. Left upper pulmonary vein
C. Left pulmonary artery
D. Right lower pulmonary vein

Figure 7.40

7.41. Figure 7.41 shows a volume rendered image. What does the number 1 refer to?

A. LAD artery
B. Left internal mammary artery
C. Diagonal
D. Right internal mammary artery

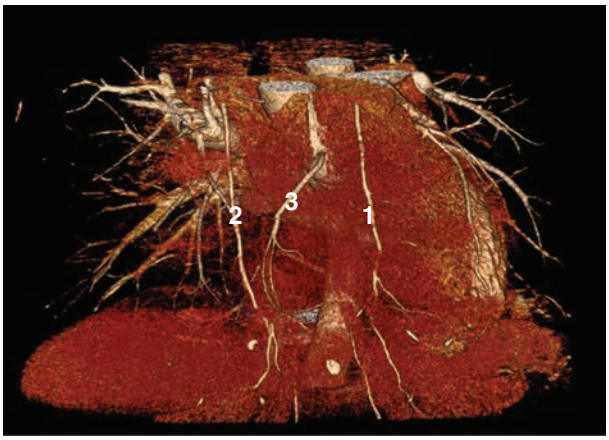

Figure 7.41

7.42. Figure 7.42 shows a volume rendered image. What does the number 1 refer to?

A. LAD artery
B. Left internal mammary artery
C. Aorta
D. Pulmonary vein

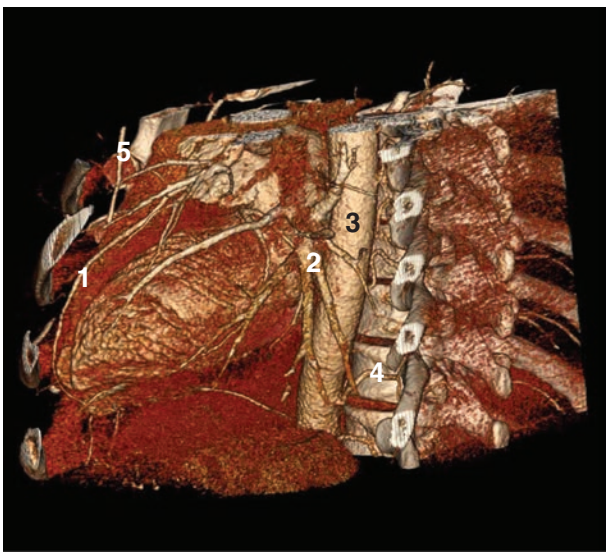

Figure 7.42

7.43. In the axial scan in Figure 7.43, what does the number 1 refer to?

A. Coronary sinus
B. Right coronary artery
C. Circumflex coronary artery
D. Anomalous left circumflex coronary artery

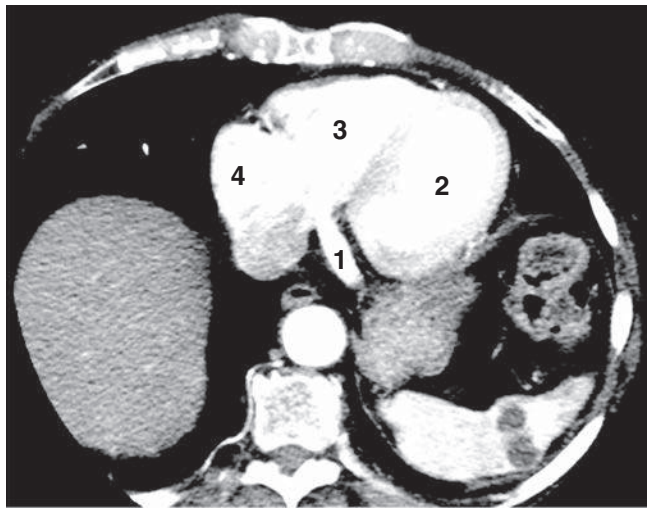

Figure 7.43

7.44. A 44-year-old man with no cardiac risk factors was seen in the ER with exertional chest pain. Axial contrast-enhanced scans are shown in Figure 7.44. What is the possible cause of his chest pain?

A. Left main coronary artery stenosis
B. Anomalous circumflex artery
C. Anomalous RCA from left coronary cusp with interarterial course
D. None of the above

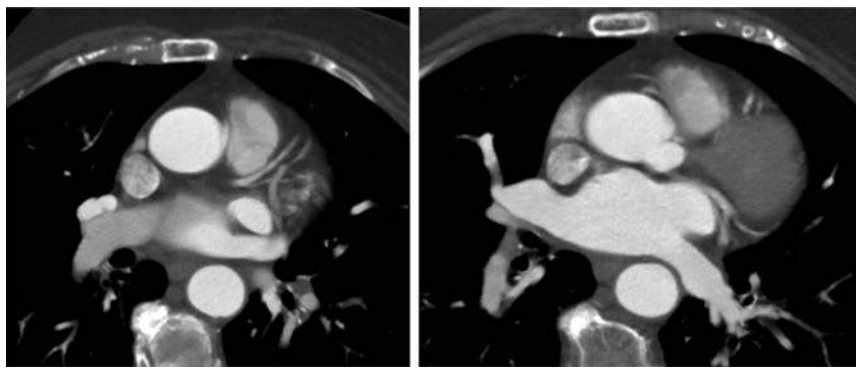

Figure 7.44

7.45. Which of the following options describes the LAD artery segment shown in Figure 7.45?

A. Normal
B. Has severe stenosis in proximal segment
C. Has a large mixed plaque in the cross-section shown
D. Has a large soft plaque in the cross-section shown

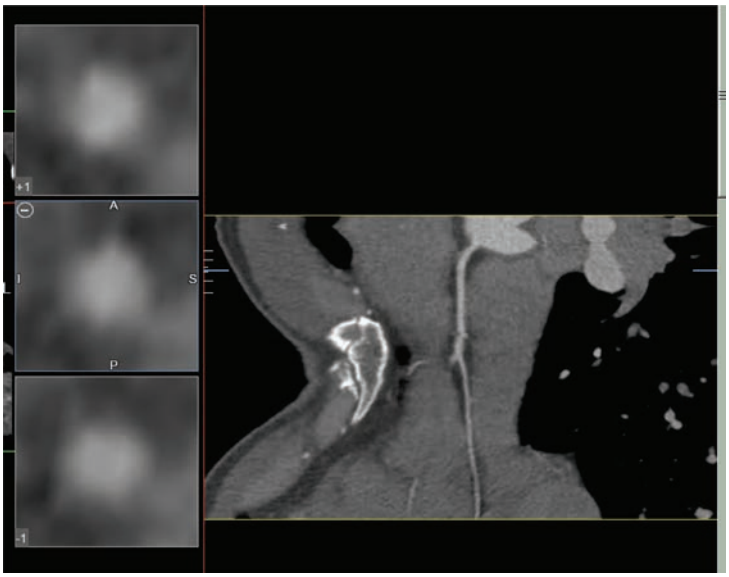

Figure 7.45

7.46. The volume rendered scan in Figure 7.46 shows what?

A. Normal coronary anatomy
B. Anomalous LCA
C. Anomalous RCA from left sinus
D. Saphenous venous graft to RCA

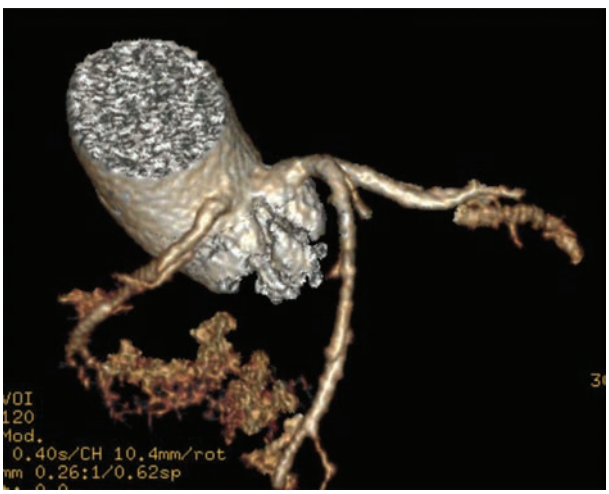

Figure 7.46

7.47. What can be said from the volume rendered scan shown in Figure 7.47?

- **A.** Has normal coronary anatomy
- **B.** Has severe LAD artery stenosis
- **C.** Need to evaluate LAD artery and other vessels using curved multiplanar reformation and centerline methods to comment about the coronaries
- **D.** Has moderate LAD artery stenosis, and stress test is indicated

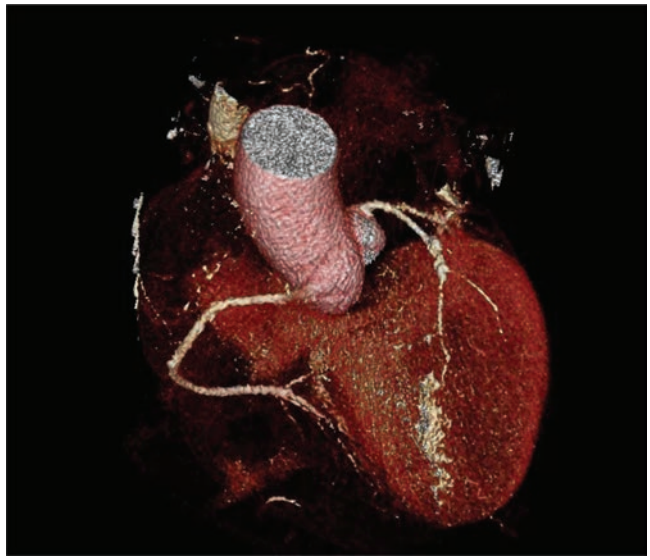

Figure 7.47

7.48. A 48-year-old patient with hypertension and diabetes mellitus was seen in the ER with atypical chest pain. Cardiac enzymes were normal. Coronary calcium distribution is shown in Figure 7.48. What would be a reasonable next step?

- **A.** Cancel coronary CTA in view of severe coronary calcification and order a stress test
- **B.** Go ahead with coronary CTA; if lesions are moderate or indeterminate, consider cardiac catheterization
- **C.** Cancel coronary CTA and treat with aspirin and high-intensity statin
- **D.** Refer for cardiac catheterization

7.49. What does the arrow in the axial scan in Figure 7.49 refer to?

- **A.** Coronary sinus
- **B.** RCA
- **C.** Circumflex coronary artery
- **D.** Anomalous circumflex artery

7.50. For transcatheter aortic valve replacement (TAVR) planning, what type of cardiac protocol is most appropriate?

- **A.** Noncontrast CT with cardiac gating
- **B.** Noncontrast CT without cardiac gating
- **C.** Contrast CT with cardiac gating
- **D.** Contrast CT without cardiac gating

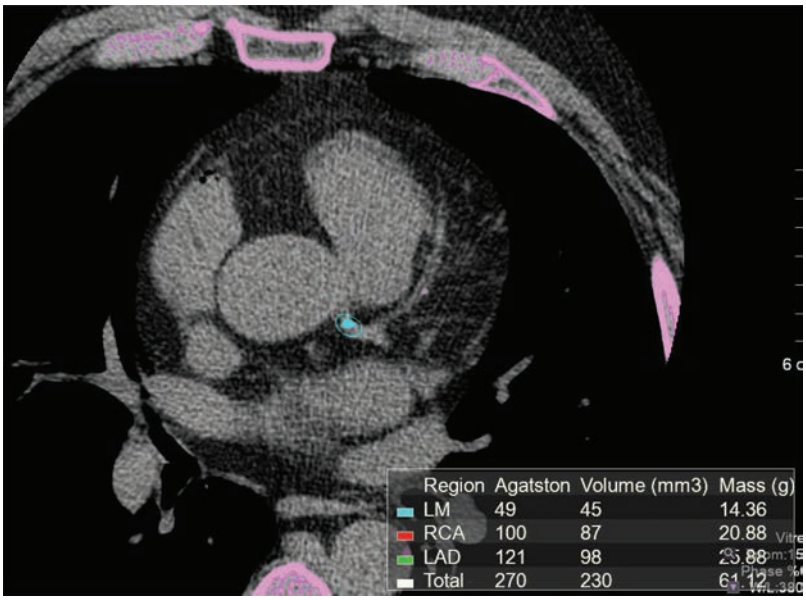

Figure 7.48

Figure 7.49

7.51. What cardiac CT measures are useful for TAVR planning?

- **A.** Aortic annulus size
- **B.** Left and right coronary height from aortic annulus
- **C.** Size of aortic sinus and sinotubular junction
- **D.** Aortic leaflet size and degree of calcification
- **E.** All of the above

7.52. The CT images shown in Figure 7.52 would permit which of the following?

- **A.** Size 23 mm TAVR
- **B.** 26 mm TAVR
- **C.** 29 mm TAVR
- **D.** Coronary height is too low for TAVR

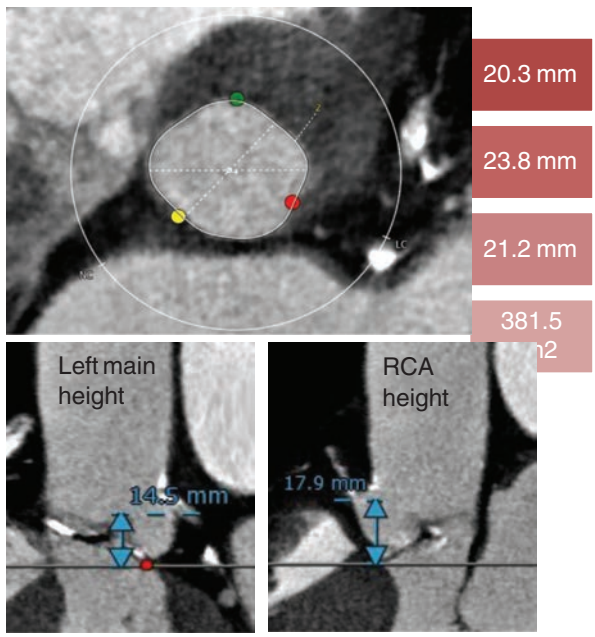

Figure 7.52

7.53. The patient in Figure 7.53 has severe calcific aortic stenosis and TAVR is being planned. Which of the following statements is correct?

- **A.** The aortic annulus is large and may need a 29 mm valve
- **B.** There is severe aortic valve calcification and this may increase risk of coronary occlusion
- **C.** The coronary height and size of the sinus and sinotubular junction are not shown and these are important in planning
- **D.** All of the above

7.54. A peripheral CTA of a patient being considered for TAVR is shown in Figure 7.54 (RCFA: right common femoral artery; RCIA: right common iliac artery; REIA: right external iliac artery). Which of the following conclusions can be drawn?

- **A.** Peripheral vessels are adequate for transfemoral approach
- **B.** Either side can be used for transfemoral approach
- **C.** Both
- **D.** Neither

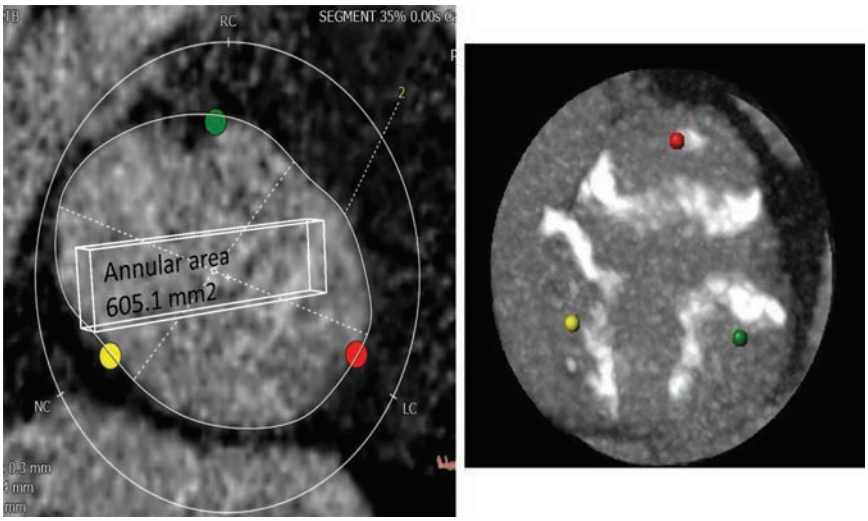

Figure 7.53

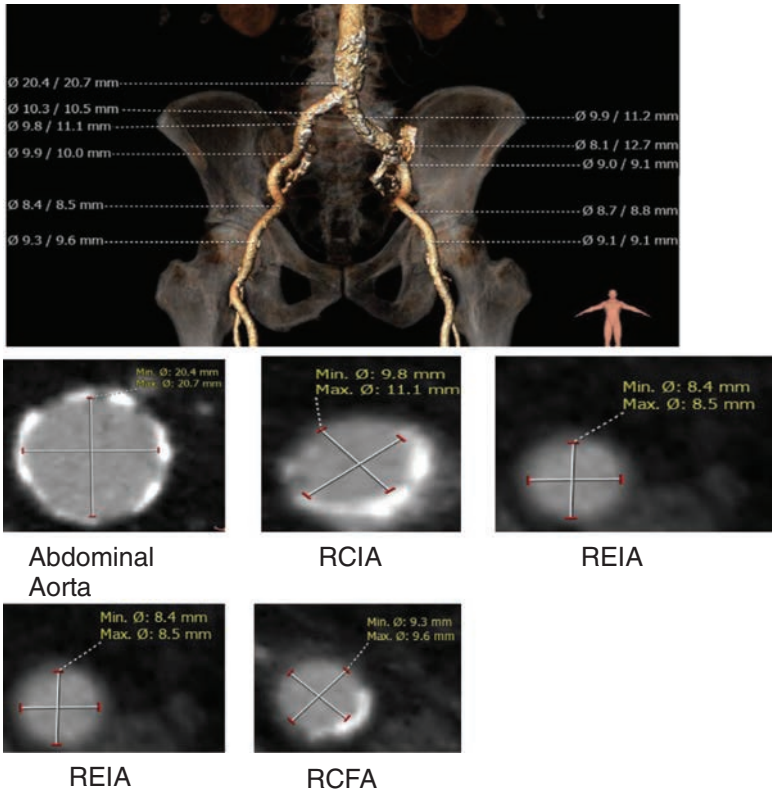

Figure 7.54

7.55. Which of the following techniques has thea potential to evaluate the functional significance of a coronary artery lesion using cardiac CT?

A. Dynamic CT–myocardiac perfusion imaging
B. Static CT–myocardiac perfusion imaging
C. Transluminal attenuation gradient assessment
D. CT–fractional flow reserve
E. All of the above
F. None of the above

7.56. Which of the following characteristics is associated with a potentially severe coronary artery stenosis?

A. Small area of stenosis
B. Greater lesion length
C. Positive remodeling
D. Low-attenuation plaque <30 HU
E. All of the above
F. None of the above

7.57. A 35-year-old patient who had undergone a Bentall procedure 2 months earlier presented with chest pain. A contrast CT axial image is shown in Figure 7.57a. What is the likely explanation for the chest pain?

A. Leaking pseudoaneurysm of the aorta
B. Occluded left coronary anastomosis
C. Occluded RCA
D. None of the above

Figure 7.57a

7.58. The patient shown in Figure 7.58 has a recent implantable cardioverter-defibrillator and presented with chest pain. What is the likely cause of the chest pain?

A. Right ventricular lead perforation
B. Inferior infarct
C. Large pericardial effusion
D. None of the above.

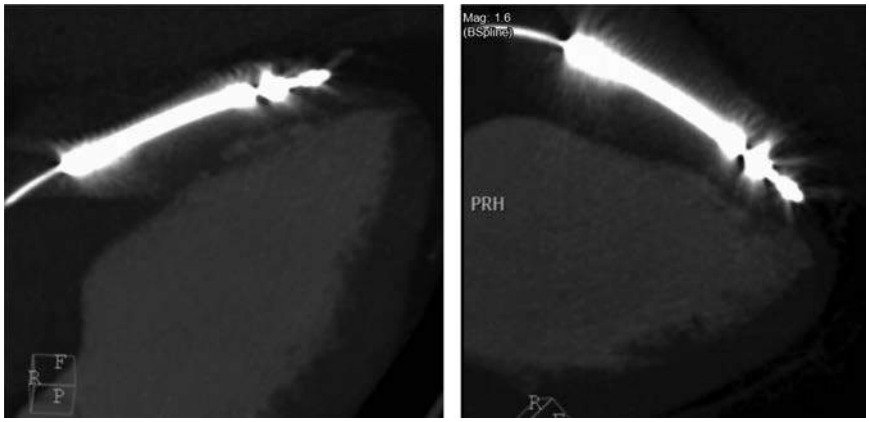

Figure 7.58

7.59. The RCA of the patient shown in Figure 7.59 shows what?

A. Severe RCA classification
B. Severe lesion in mid segment
C. RCA stent
D. Normal RCA

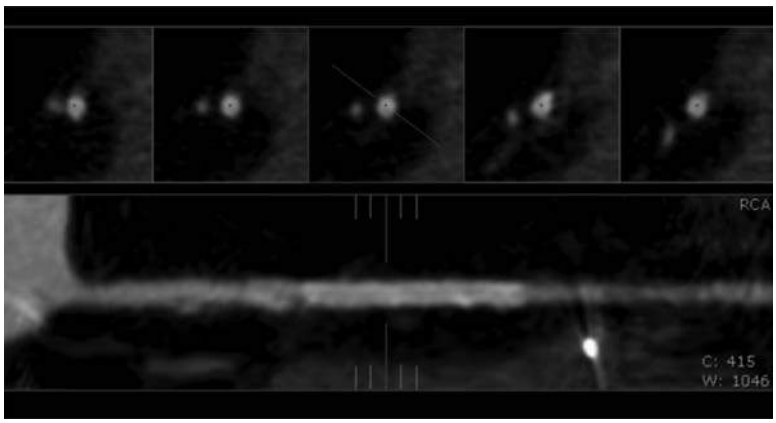

Figure 7.59

7.60. The LAD artery of the patient shown in Figure 7.60 is described by which of the following?

A. Normal anatomy
B. Mid LAD artery lesion.
C. Myocardial bridging
D. None of the above

7.61. A 40-year-old truck driver passed out while loading his truck. There were no other medical problems. A chest CT (Figure 7.61a) was performed in the ER to rule out pulmonary embolism because of his leg swelling and positive D-dimer. Which of the following is a possible cause of his syncope?

A. Pulmonary embolism
B. Large pericardial effusion
C. Anomalous origin of left coronary artery
D. Anomalous origin of RCA.

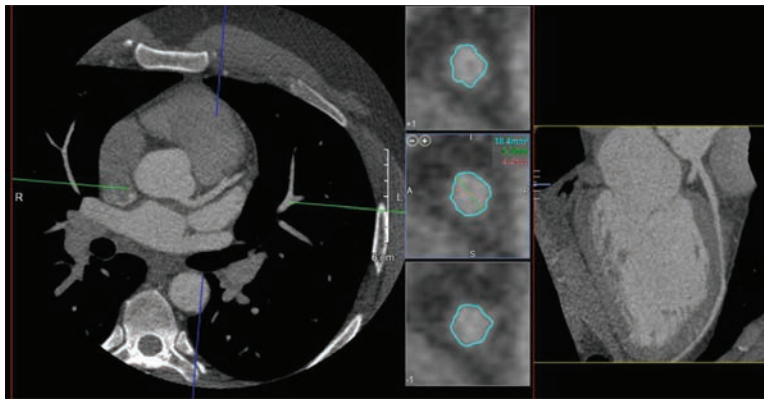

Figure 7.60

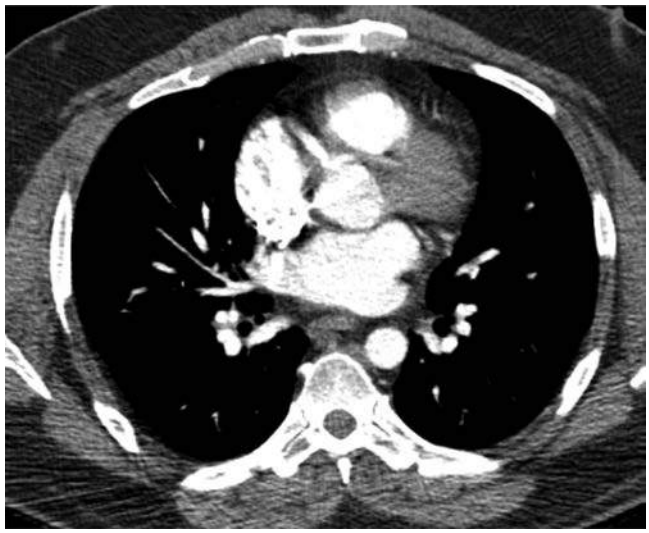

Figure 7.61a

7.62. What would be your recommendation to the patient in Question 7.61?

- **A.** Reassurance
- **B.** Exercise stress test
- **C.** Stress echo
- **D.** Coronary angiography and possible left coronary reimplant

7.63. An 83-year-old woman presented with acute central chest pain. Chest CT with contrast was obtained in the ER (Figure 7.63a). What are the images suggestive of?

- **A.** Stanford type A aortic dissection
- **B.** Stanford type B aortic dissection
- **C.** Pulmonary embolism
- **D.** Intramural hematoma

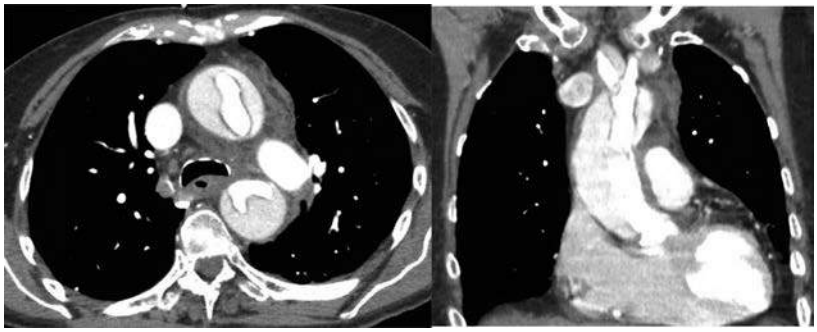

Figure 7.63a

Answers

7.1. A. Prospective gated noncontrast.
Prospective gating reduces radiation exposure. Contrast should not be used. Generally, a Hounsfield unit (HU) threshold of 130 units is used to detect calcium.

7.2. C. 3 mm.
Outcome data are based on this slice thickness.

7.3. B. Retrospective, gated with contrast.
For left ventricle function assessment the left ventricle has to be opacified; scan should be gated and should have all phases.

7.4. A. Prospectively gated, electrocardiogram (ECG)-triggered cardiac computed tomography angiography (CTA).
This is associated with an absorbed radiation dose of about 3 mSv, compared with about 15 mSv for retrospectively gated, cardiac CTA, 7 mSv for coronary angiography, and about 15 mSv for stress perfusion scan with sestamibi.

7.5. C. Dual isotope myocardial perfusion scan with thallium and Sestamibi.
This is associated with a radiation exposure of about 25 mSv. Dose modulation during prospective gating reduces radiation dose by about 40%, but prospective gating reduces by about 85%.

7.6. B. Women.
The young are also at high risk as they have more years to live after radiation exposure, such that cancer phenotype can develop following DNA damage.

7.7. D. Breast.
Breast and skin get the highest radiation dose, and then lung, heart, and esophagus in descending order.

7.8. D. All of the above.
Radiation dose is proportional to tube current and square of tube voltage. It is inversely proportional to pitch.

7.9. D. 3.0.
Radiation is inversely proportional to pitch. Hence, compared with a pitch of 1, 3 is associated with a third of the radiation and a pitch of 0.4 is associated with 2.5 times the radiation.

7.10. D. Cardiac MRI with gadolinium vasodilator stress.
There is no radiation with MRI. It uses radiofrequency pulses.

7.11. B. Patient with hypertension, ECG shows nonspecific ST–T changes, negative cardiac enzymes.
This is a level 4 chest pain patient; that is, atypical chest pain with a thrombolysis in myocardial infarction (TIMI) score <2. The other two scenarios are level 3 and are appropriate for stress testing. Coronary CTA is appropriate in patients with low to intermediate probability of coronary artery disease (CAD). See Box 7.1.

7.12. D. All of the above.
Beta blockers in oral and intravenous form are traditionally used. In those with reactive airway disease, calcium channel blockers are an option. In those with low blood pressure who may not tolerate either of these, ivabradine, which selectively slows the sinus node without lowering blood pressure, is an option. This drug is approved for treatment of heart failure.

7.13. C. Decreasing tube current by 25%.
This will reduce radiation dose by about 40%, whereas A and B options reduce radiation dose by only 25%.

7.14. C. Effective radiation dose (ERD).
ERD is expressed in millisieverts. CTDI is the radiation dose delivered by the machine for a given scan parameter based on phantom simulation. DLP (mGy cm) takes into consideration scan length: DLP = CTDIvol × scan length. ERD = DLP × 0.014 (where 0.014 is a conversion factor) for cardiac CTA. Hence, for a DLP of 1000 mGy cm, the ERD for cardiac CT is 1000 × 0.014 = 14 mSv

7.15. C. 5 mSv.
50 mSv is for adult radiation workers.

7.16. C. 0.14 mSv.
This is very low with low risk. Even with shielding, the fetus will get some scattered radiation.

7.17. B. −50 HU.
Water is 0 HU, air is −1000 HU.

7.18. B. 130.

7.19. D. All of the above.
Decreasing pitch reduces noise as well, but it increases radiation.

7.20. D. All of the above.
Multiple passes and signal averaging improve signal strength and reduce noise.

7.21. A. 0.5 mm × 0.5 mm.

$$\text{Pixel size} = \frac{\text{FOV}}{\text{matrix}}$$

7.22. C. Both.

7.23. D. Number of detector rows.
This affects the amount of coverage during one cardiac cycle, but not temporal or spatial resolution.

7.24. A. Increasing slice thickness.
This gives more photons or energy or signal. To reduce noise by half, you have to increase slice thickness fourfold, as noise is inversely proportional to the square of the number of photons.

7.25. C. Both.
With dual energy, you can subtract calcium from the image. Reconstruction with sharp filter has to be performed on the scanner raw data.

7.26. E. All of the above.

7.27. E. All of the above.

7.28. B. LAD coronary artery stent 2 years ago 2.5 mm.
It is inappropriate to perform coronary CTA when stent size is <3 mm. In others with symptoms, it is of uncertain significance.

7.29. A. Left main coronary artery stenting with stent size ≥3 mm.
It is inappropriate to do in other asymptomatic patients. Presence of symptoms, stent size of ≥3 mm, and left main coronary artery location make coronary CTA increasingly appropriate. Use of techniques such as dual-source CT or appropriate processing with iterative processing and use of sharp filters would be helpful for better quality images.

7.30. E. All of the above.

7.31. B. Normal RCA origin, not calcified.

7.32. B. Normal left main coronary artery origin, not calcified.

7.33. A. Pulmonary veins: left upper, left lower, right upper, right lower respectively.

7.34. A. Left atrial appendage.
2: Body of left atrium; 3: ascending aorta; 4: right ventricle outflow tract, 5: descending thoracic aorta.

7.35. A. Ascending aorta.
2: Descending aorta; 3: vertebral body; 4: roof of left atrium; 5: pulmonary vein.

7.36. A. LAD artery.
2: Left atrial appendage; 3: diagonal artery.

7.37. D. Right ventricle branch of RCA.
1: RCA; 2: right ventricular outflow tract (RVOT); 3: LAD artery; 4: right pulmonary veins.

7.38. A. RCA.
The RCA is in the right atrioventricular groove. The pericardiophrenic bundle would be outside the pericardium. 2: bronchus; 3: right ventricle; 4: left ventricle; 5: descending thoracic aorta.

7.39. A. Ascending thoracic aorta.
1: Ascending aorta.

7.40. A. Left lower pulmonary vein.
2: Descending thoracic aorta; 3: ascending aorta; 4: left upper pulmonary vein; 5: right lower pulmonary vein; 6: right upper pulmonary vein. Figure 7.40 is a view from the back.

7.41. B. Left internal mammary artery.
2: Right internal mammary artery; 3: RCA.

7.42. A. LAD artery.
2: Left lower pulmonary vein; 3: descending thoracic aorta; 4: intercostal artery; 5: left internal mammary artery.

7.43. A. Coronary sinus.
2: Left ventricle; 3: right ventricle; 4: right atrium.

7.44. C. Anomalous RCA from left coronary cusp with interarterial course.
Note that the proximal course is between aorta and RVOT. Circumflex courses normally. No LAD artery stenosis is seen in the images in Figure 7.44.

7.45. A. Normal.

7.46. C. Anomalous RCA from left sinus.
There is an interarterial course between the aorta and pulmonary artery (pulmonary artery not shown).

7.47. C. Need to evaluate LAD artery and other vessels using curved multiplanar reformation and centerline methods to comment about the coronaries.
One cannot comment about stenosis severity from volume rendered images.

7.48. B. Go ahead with coronary CTA; if lesions are moderate or indeterminate, consider cardiac catheterization.
Despite two risk factors, patient is at low to intermediate risk for CAD and coronary CTA (TIMI score 2 and level 4) is appropriate. Coronary calcification may impede lumen visualization, but coronary calcium score is not >400. Use of interactive processing and using sharp filter or dual-source CT would be helpful to better evaluate calcified areas.

7.49. B. RCA.
Distal RCA in right posterior atrioventricular groove.

7.50. C. Contrast CT with cardiac gating.
This could be prospectively gated for midsystolic phase or retrospectively gated so that systolic phase can be reconstructed. The measurements of aortic annulus should be obtained in systole and contrast is essential for blood–wall interface visualization.

7.51. E. All of the above.
Aortic annulus is best sized by CT. Coronary height of >10 mm assures that the aortic leaflets may not occlude coronary ostia after TAVR. Amount of calcification and length of aortic leaflets also have a bearing on potential to occlude coronary ostia. If the aortic sinus is small and coronary height is less, risk of coronary occlusion is high and there may be a need to wire the coronary before TAVR.

7.52. A. Size 23 mm TAVR.
Based on annular dimensions and area. Coronary height >10 mm is adequate.

7.53. D. All of the above.

7.54. C. Both.
The vessels are >7 mm, which would permit any delivery sheath. With the newer generation valves even 5–6 mm vessels are adequate.

7.55. E. All of the above.

7.56. E. All of the above.

7.57. A. Leaking pseudoaneurysm of the aorta.
Anteriorly, as shown by the arrow in Figure 7.57b – possibly related to RCA anatomosis.

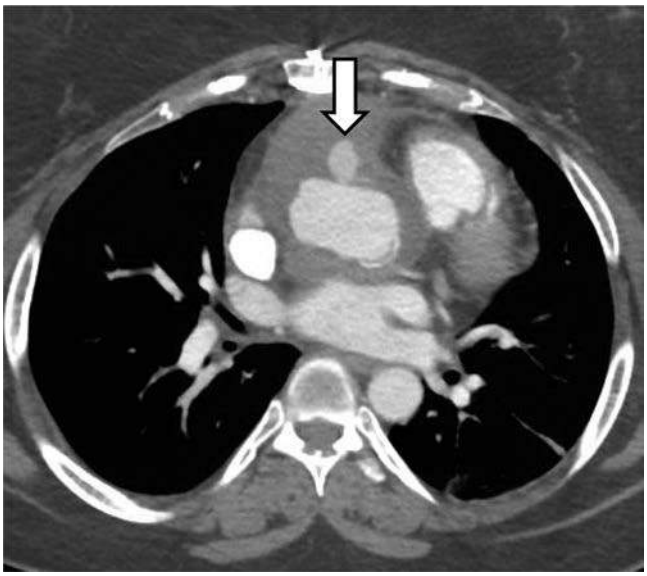

Figure 7.57b

7.58. A. Right ventricular lead perforation.
Note that the tip of the lead is beyond the right ventricle wall and in epicardial fat or beyond.

7.59. C. RCA stent.
The RCA stent is in the middle of the segment shown. CTA is not very optimal to evaluate for lesions within the stent, though the stent looks patent.

7.60. C. Myocardial bridging.
Note the smooth narrowing and intramyocardial course.

7.61. C. Anomalous origin of left coronary artery.
Note that the left coronary artery (arrow in Figure 7.61b) is originating from right coronary sinus and courses in between the aorta and RVOT. This course has elevated risk of sudden death, though it is commonly found at routine autopsies. Ventricular arrhythmia brought on by exertion is a possibility.

7.62. D. Coronary angiography and possible left coronary reimplant.
As the patient had syncope and is in a high-risk occupation, this is very justified. If he was asymptomatic, it is controversial what would be the best management, but most would lean toward coronary reimplant or a graft on the coronary. Reimplant may be associated with recurrent ostial stenosis of the left main coronary artery and needs close monitoring. A stress test would be reasonable if the patient was asymptomatic and had normal left ventricular function. However, the American College of Cardiology/American Heart Association guidelines recommend surgical correction for all coronaries coursing between great vessels.

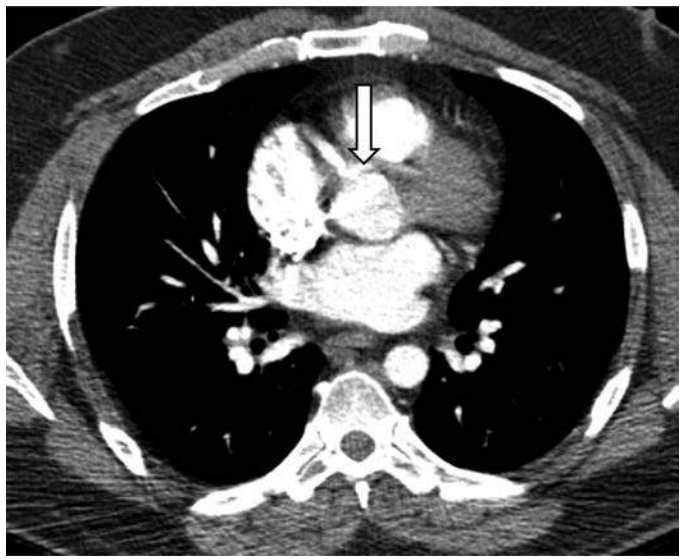

Figure 7.61b

7.63. A. Stanford type A aortic dissection.

This involves ascending and descending aorta (DeBakey type II). The axial image on the left of Figure 7.63b shows the true lumen in the ascending aorta (blue arrow) and descending aorta (red arrow). The coronal scan on the right of Figure 7.63b shows the ascending aorta with both true and false lumens. The false lumen is opacified by the contrast as there is flow in that; intramural hematoma does not get opacified by the contrast. Type B (DeBakey type III) involves descending aorta only and type I involves ascending aorta only. Transesophageal echocardiography, CT, and MRI are equally sensitive and specific for the diagnosis of aortic dissection.

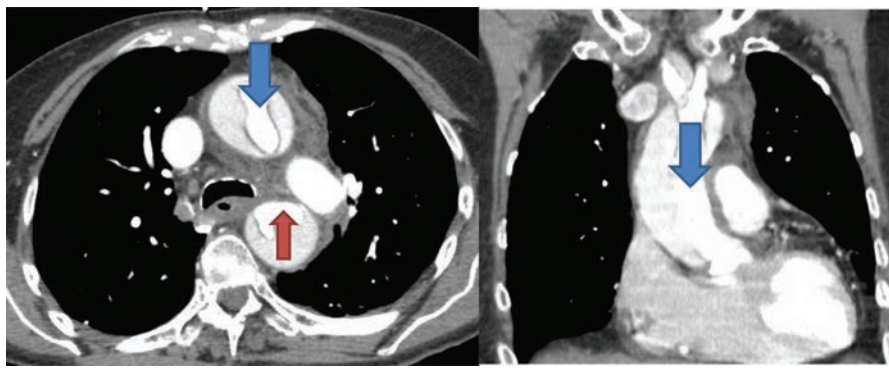

Figure 7.63b

Box 7.1 Suggested Chest Pain Triaging in ER and Role of Coronary CTA

Suggested steps in chest pain triaging in the ER (at discretion of ER physician)

1. Obtain details on prognostic variables
2. Assignment to level in chest pain protocol
3. Choice of testing based on the level
4. Incorporation of coronary CTA test results and disposition
5. Follow-up plan

1. Obtain details on prognostic variables

- Type of chest pain (angina, atypical, noncardiac)
- Age ≥65
- ≥3 coronary risk factors
- Known CAD
- Aspirin use in last 7 days
- ≥2 chest pain episodes in 24 h
- ST deviation ≥0.5 mm
- Elevated cardiac enzymes
- TIMI score (1 point each for age >65, >3 coronary risk factors, known CAD, aspirin use in last 7 days, >2 chest pain episodes in 24 h, ST deviation >0.5 mm, elevated cardiac enzymes)

2 and 3. Assignment to level in chest pain protocol and appropriate testing

See Figure B7.1.

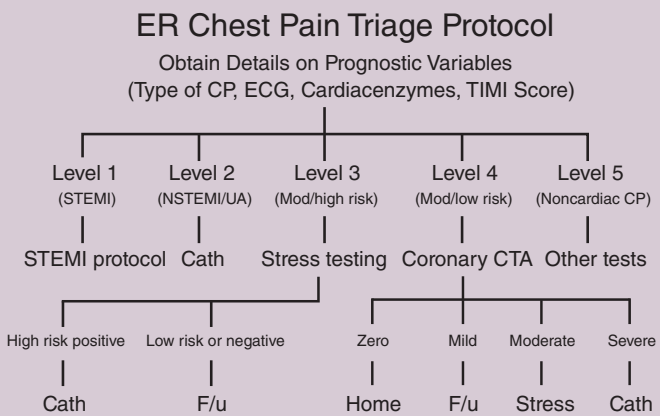

Figure B7.1

- Level 1: ST-elevation myocardial infarction (STEMI) → STEMI protocol
- Level 2: non-STEMI, unstable angina → cardiac catheterization
- Level 3: TIMI score >2, typical angina, moderate ACS risk → stress testing

- Level 4: low to intermediate risk of ACS, TIMI score ≤2 → coronary CTA
- Level 5: noncardiac chest pain → look for noncardiac causes based on presentation

4 and 5. Incorporation of coronary CTA test results and disposition

- Zero: no stenosis → discharge home
- Mild: 1–49% → discharge home with follow-up within a week
- Moderate: 50–69% → noninvasive testing (stress test)
- Severe ≥70%: → admit and catheterization

Choice of Stress Test

- If a patient can walk and ECG is normal → exercise stress ECG
- If a patient can walk and ECG is abnormal (not LBBB or RV paced rhythm) → exercise stress with imaging (echo or nuclear perfusion)
- If LBBBB or paced rhythm → Lexiscan nuclear perfusion preferable (exercise perfusion results in false-positive perfusion defects). Dobutamine or exercise stress echo are acceptable as well
- If a patient cannot walk → pharmacological stress test (dobutamine echocardiogram), vasodilator (Lexiscan) nuclear stress, vasodilator (Lexiscan) cardiac MRI when available

Cardiac Catheterization

8

8.1. Which of the images A, B, or C in Figure 8.1 depicts the correct anatomic placement of the Kelly to identify the site of sheath entry for transfemoral access?

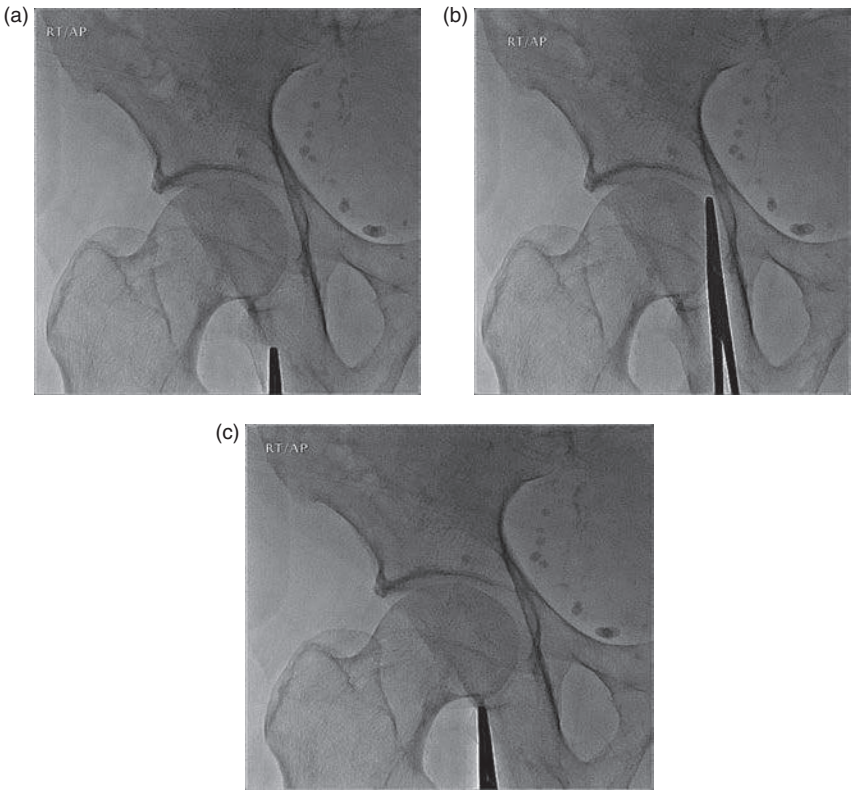

Figure 8.1

8.2. Where should be the ideal location of sheath entry in transfemoral access during cardiac catheterization?

A. Above the inferior epigastric artery to stay as far away from the common femoral bifurcation as possible
B. In the mid common femoral artery above the bifurcation
C. In the proximal profunda femoris
D. In the superficial femoral artery

Cardiology Board Review, First Edition. Ramdas G. Pai, Padmini Varadarajan and Sudha M. Pai.
© 2018 John Wiley & Sons, Ltd. Published 2018 by John Wiley & Sons, Ltd.

8.3. What are the possible complications associated with the access depicted in Figure 8.3?

A. No complications as the access appears appropriate
B. Pseudoaneurysm and arteriovenous malformations
C. Retroperitoneal hemorrhage
D. Intracranial hemorrhage

Figure 8.3

8.4. What physical sign would be expected if a complication occurred from a "low" stick?

A. A continuous bruit over the access site
B. Bruising over the skin
C. A sudden and severe drop in blood pressure
D. Angina chest discomfort

8.5. A 70-year-old man underwent a diagnostic cardiac catheterization via the right transfemoral approach prior to aortic valve replacement. Approximately 1 h later the nurse reports to you that he appears agitated and is complaining of lower abdominal discomfort. His systolic blood pressure is now 90 mmHg. The blood pressure prior to the procedure was 150 mmHg systolic. What is the next best step?

A. Immediately start intravenous fluid and blood transfusion and obtain a non-contrast computed tomography (CT) of the abdomen and pelvis.
B. Immediately start intravenous fluid and monitor blood pressure response
C. Reassure the nurse that his is likely a vagal response and request that she monitor the blood pressure closely
D. Immediately take the patient back to the catheterization laboratory to reevaluate his femoral anatomy.

8.6. Which of the femoral angiograms A or B in Figure 8.6 is most likely to be associated with the patient in Question 8.5?

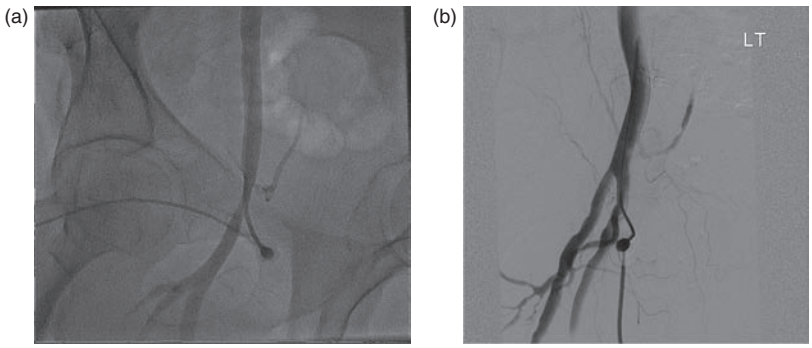

Figure 8.6

8.7. A 68-year old man underwent an uncomplicated percutaneous coronary intervention of the mid left anterior descending (LAD) artery. You are called about 30 min after the procedure that there is a large hematoma over the femoral access site. Manual pressure is applied for 40 min but the hematoma quickly reforms. What is the next best step?

A. Immediately start intravenous fluid and blood transfusion and obtain a non-contrast CT of the abdomen and pelvis
B. Immediately start intravenous fluid, apply a clamp for compression, and monitor blood pressure response
C. Reassure the nurse that his is likely a vagal response and request that she monitor the blood pressure closely
D. Immediately take the patient back to the catheterization laboratory to reevaluate his femoral anatomy

8.8. A 56-year-old man presents to the emergency department complaining of discomfort in the right groin. He underwent a diagnostic cardiac catheterization about 3 days ago. Examination reveals a loud, continuous bruit over the femoral artery. What test should be ordered next?

A. A complete lower extremity angiogram, as this patient likely has concomitant peripheral vascular disease
B. A CT scan of the pelvis
C. An ultrasound evaluation of the right groin
D. No work-up is needed as he likely has chronic peripheral vascular disease and the discomfort is normal in this time frame

8.9. A patient is being evaluated and consented prior to an outpatient cardiac catheterization. He reports that he had a CT angiogram about 2 years ago. After the procedure he developed hives and pruritus. His physician prescribed a medication for a week at that time, the name of which he cannot recall. How should he be managed?

A. Given that the procedure was remote, this is likely an idiosyncratic reaction; proceed with the planned procedure without addition evaluation or medication

B. He may have had a mild contrast reaction, which is unlikely to recur; proceed as planned without addition evaluation or medication
C. He may have had a mild contrast reaction; administer an antihistamine prior to the planned procedure
D. He may have had a mild contrast reaction; administer an antihistamine and a short course of oral steroids prior to the procedure

8.10. You are in the midst of completing a diagnostic cardiac catheterization on a patient. His coronary anatomy is angiographically normal and the left ventricular function is normal. He suddenly becomes profoundly hypotensive. He is fully alert and able to answer questions. A repeat angiography again demonstrates angiographically normal coronary arteries. A stat echocardiogram demonstrates that the left ventricular function is normal and there is no evidence of pericardial effusion. What is the next best step in his management?

A. Reverse the sedation and monitor hemodynamics
B. Administer a bolus of normal saline and monitor hemodynamic response
C. Start intravenous normal saline bolus followed by continued infusion and administer intravenous glucocorticoids
D. Start dopamine infusion immediately and admit to the intensive care unit. Consult cardiothoracic surgery

8.11. Which of the following statement is correct regarding sedation during transradial access?

A. No sedation is required as this is a minimal painful and quick access
B. Moderate sedation to achieve a completely comfortable response
C. Deep sedation, making sure that airway is protected but no response to painful stimuli
D. General anesthesia, as multiple sticks are often required and significant pain may occur

8.12. The right radial artery is successfully accessed for coronary angiography in a 55-year-old woman. The sheath is advanced without difficulty. What is the immediate next step?

A. Proceed with diagnostic catheter advanced under fluoroscopic guidance immediately as access may spasm
B. Administer a pharmacologic cocktail containing heparin only prior to beginning catheterization
C. Administer a pharmacologic cocktail containing heparin and a vasodilator prior to beginning catheterization
D. Administer a pharmacologic cocktail containing only a vasodilator prior to beginning catheterization

8.13. The cardiac catheterization is successfully completed in the patient in Question 8.12. As the sheath was being removed there is significant tension noted and the patient suddenly complained about pain in the forearm? How should you proceed?

A. This is a normal response; continue to steady negative tension and withdraw the sheath
B. Stop immediately, as the sheath is entrapped by arterial spasm; consult vascular surgery immediately

C. Administer a repeat bolus of the pharmacologic cocktail containing vasodilator and heparin; reattempt retraction gently
D. Repeat sedation only and reattempt when the patient is sedated and able to tolerate the discomfort

8.14. A 6-French JL-4 is used to engage the left main coronary artery for coronary angiography. The pressure waveform in Figure 8.14 is recorded. What should you do next?
A. Proceed as usual with coronary angiogram
B. Retract the catheter and reposition the engagement; if the same waveform is present, proceed as usual
C. Retract the catheter and reposition the engagement; if the same waveform is detected then give a small gentle puff of contrast to visualize the anatomy
D. Abandon the procedure, as there may be severe left main stenosis; consult cardiothoracic surgery

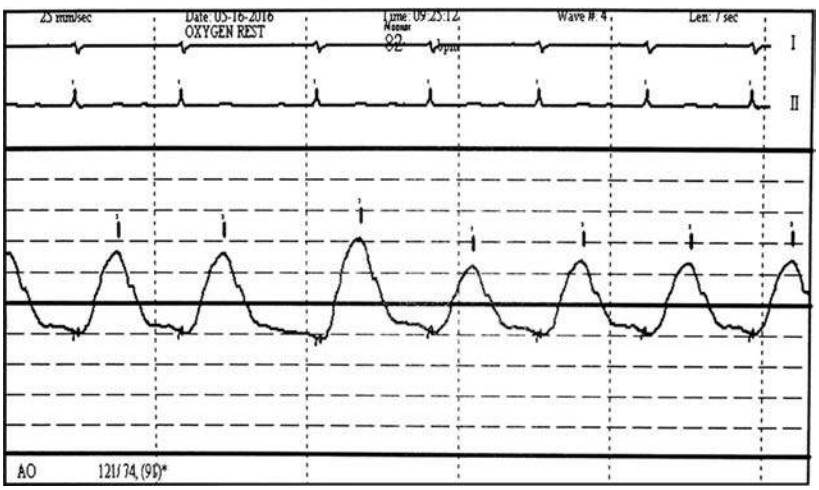

Figure 8.14

8.15. Coronary angiography is performed on a patient. What is depicted in the angiogram shown in Figure 8.15a?
A. Artifact from streaming of the contrast
B. A spiral dissection
C. Injection into the conus branch
D. Occluded right coronary artery

8.16. What should be the next step in treating the patient in Question 8.12?
A. Give a more brisk contrast injection to more forcefully displace the blood with contrast and better image the vessel
B. Advance a wire carefully to the distal vessel followed by a small-caliber over-the-wire balloon to verify intraluminal position
C. Proceed with angiography of the right coronary system, as no treatment is required for vessel tortuosity
D. Advance a floppy wire and treat the individual stenosis with stent implantation

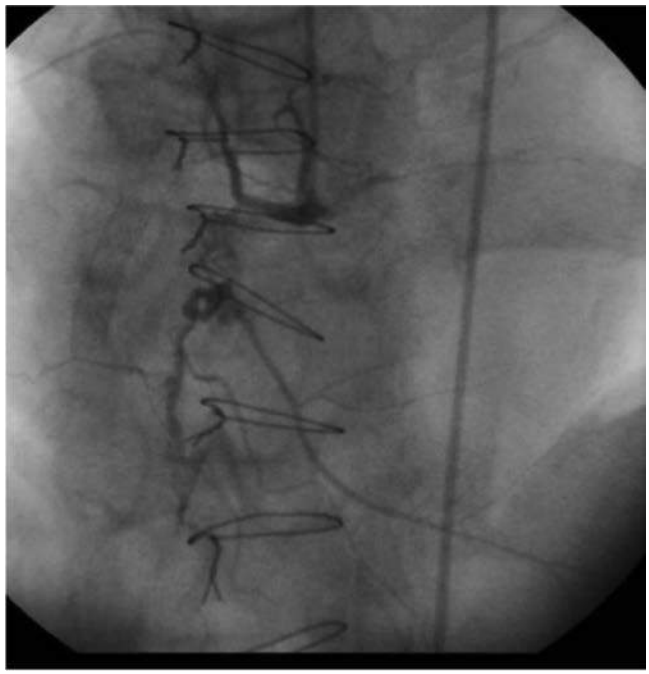

Figure 8.15a

8.17. What is the aortogram in Figure 8.17 suggestive of?
- **A.** Occluded left main artery
- **B.** Occluded RCA
- **C.** Aortic dissection
- **D.** Aortic intramural hematoma

8.18. The patient in Figure 8.18 presented with cardiogenic shock. What does the image show?
- **A.** Impella, RCA stent
- **B.** Intra-aortic balloon pump
- **C.** RCA stent and tandem heart catheter
- **D.** None of the above

8.19. What does the coronary angiogram in Figure 8.19 show?
- **A.** Significant distal left main coronary artery lesion
- **B.** LAD stenosis
- **C.** Severe circumflex lesion
- **D.** None of the above

8.20. What has the patient in Figure 8.20 likely presented with?
- **A.** Acute anterior ST-elevation myocardial infarction (STEMI)
- **B.** Acute inferior STEMI
- **C.** Chronic stable angina
- **D.** None of the above

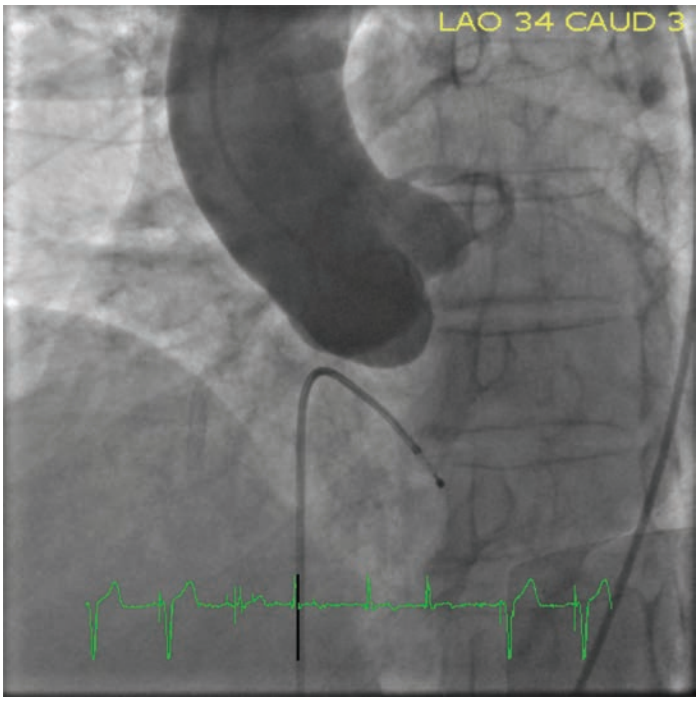

Figure 8.17

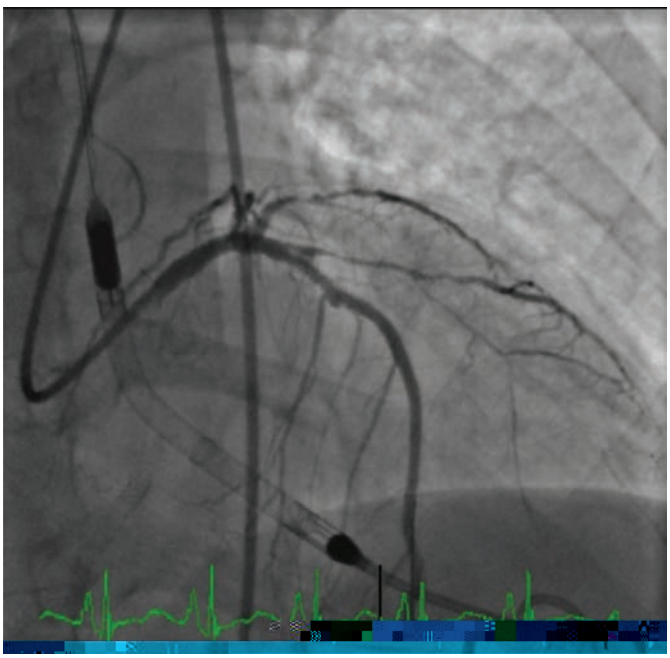

Figure 8.18

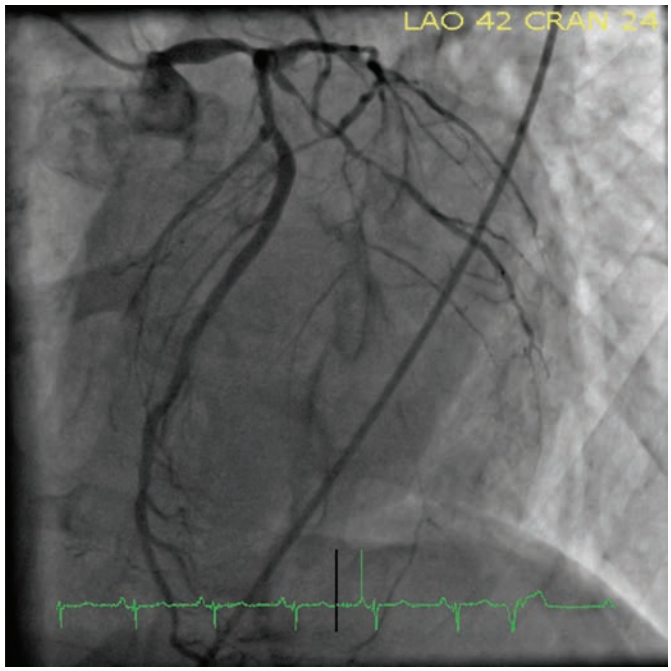

Figure 8.19

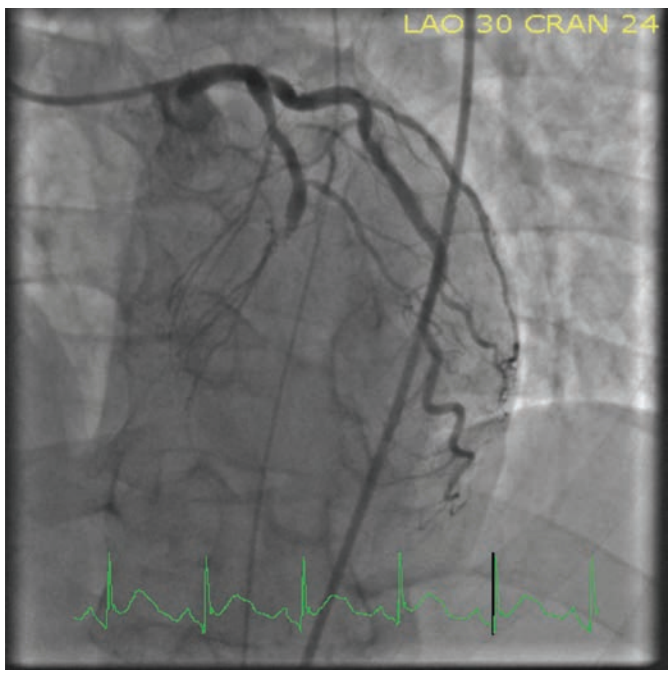

Figure 8.20

Answers

8.1. C.

An instrument such as a Kelly is placed over the patient skin to fluoroscopically identify the inferomedial femoral head. This is the ideal location for the needle to enter the skin at such an angle as to facilitate entry into the common femoral artery below the inferior epigastric artery and above the common femoral bifurcation. Entry at this location minimizes vascular complications.

8.2. B. In the mid common femoral artery above the bifurcation.

The ideal location for sheath entry into the common femoral artery is below the inferior epigastric artery and above the bifurcation to minimize vascular complications.

8.3. B. Pseudoaneurysm and arteriovenous malformations.

This sheath has entered the superficial femoral artery and is considered a low stick. Low sticks are associated with arteriovenous fistulas and pseudoaneurysms as potential vascular complications.

8.4. A. A continuous bruit over the access site.

A low stick could result in an arteriovenous fistula or pseudoaneurysm. Physical examination would reveal a continuous murmur on auscultation over the arteriotomy site.

8.5. A. Immediately start intravenous fluid and blood transfusion and obtain a noncontrast CT of the abdomen and pelvis.

This patient most likely has a retroperitoneal hemorrhage. The sudden drop in blood pressure and the abdominal discomfort are big clues to this diagnosis. He should be immediately resuscitated with intravenous fluids and should receive a blood transfusion. A noncontrast CT scan of the abdomen and pelvis should be ordered when he is hemodynamically stable to confirm the diagnosis.

8.6. A.

The first angiogram demonstrates a "high" stick just at the inferior epigastric artery. A high stick is associated with a retroperitoneal hemorrhage.

8.7. D. Immediately take the patient back to the catheterization laboratory to reevaluate his femoral anatomy.

A hematoma over the arteriotomy may develop from inadequate manual compression, failure of closure device, or vessel trauma. In a patient with a hematoma that is refractory to prolonged attempts at hemostasis with manual compression, the appropriate step would be to reevaluate the femoral anatomy. This allows for efficient decision making in management of any potential vascular complication.

8.8. C. An ultrasound evaluation of the right groin.

An ultrasound is the test with the highest initial yield in this patient. It will identify potential local vascular complications such as a pseudoaneurysm, which is the most likely diagnosis.

8.9. C. He may have had a mild contrast reaction; administer an antihistamine prior to the planned procedure.

This patient likely had a mild contrast reaction and should be pretreated with antihistamines such as diphenhydramine 50 mg about 1 h before the procedure.

8.10. C. Start intravenous normal saline bolus followed by continued infusion and administer intravenous glucocorticoids.

This patient is most likely having an immediate adverse contrast reaction. The angiography should be immediately stopped and he should be resuscitated with intravenous fluids. Glucocorticoids may be administered to suppress the immune response but will not be effective immediately. Epinephrine injection may be needed. In refractory or severe cases, vasopressor infusion may be needed to temporize the situation.

8.11. B. Moderate sedation to achieve a completely comfortable response.

Adequate moderate sedation is essential in transradial access as pain and anxiety may lead to more arterial spasm.

8.12. C. Administer a pharmacologic cocktail containing heparin and a vasodilator prior to beginning catheterization.

The radial artery is small in caliber and prone to spasm; therefore, after radial access, it is generally recommended to administer a pharmacologic cocktail of heparin and a vasodilator. Different regimens and dosages have been recommended. One such option is 2000 units of heparin, 200 μg of nitroglycerine, and 2.5 mg of verapamil.

8.13. C. Administer a repeat bolus of the pharmacologic cocktail containing vasodilator and heparin; reattempt retraction gently.

If there is resistance while maneuvering catheters via the transradial approach, vasospasm should be immediately suspected. Aggressively removing the catheter may result in evulsion of the artery. Therefore, repeating the pharmacologic cocktail of heparin and vasodilators is the most prudent course of action. Sedating the patient is appropriate, though not as a stand-alone therapy.

8.14. C. Retract the catheter and reposition the engagement; if the same waveform is detected then give a small gentle puff of contrast to visualize the anatomy.

The example shown is of a ventricularized arterial waveform. This is recognized at a slight decrease in systolic pressure but a large decrease in diastolic pressure. There is also a loss of or significant smoothing out of the dicrotic notch. It is commonly encountered when the angiography catheter passes through or is against a significant coronary stenosis. Readjusting the catheter to verify positioning is important before continuing on with the angiography. If the same waveform is verified then a gentle "puff" of injection can be performed to visualize the anatomy and the potential cause of the waveform.

8.15. D. Occluded right coronary artery.

The arrow in Figure 8.15b points to occluded proximal right coronary artery with bridging collaterals. The patient had prior coronary artery bypass surgery.

8.16. B. Advance a wire carefully to the distal vessel followed by a small-caliber over-the-wire balloon to verify intraluminal position.

A common technique in treating a coronary dissection is to leave the first wire in place within the dissection plane. A second wire is then attempted to be advanced into the true lumen. The first wire may act both as a guide as to the location of the dissection plane and also may deflect the second wire. Once the wire is advanced successfully a small balloon may be advanced and dye injection performed to confirm intraluminal position.

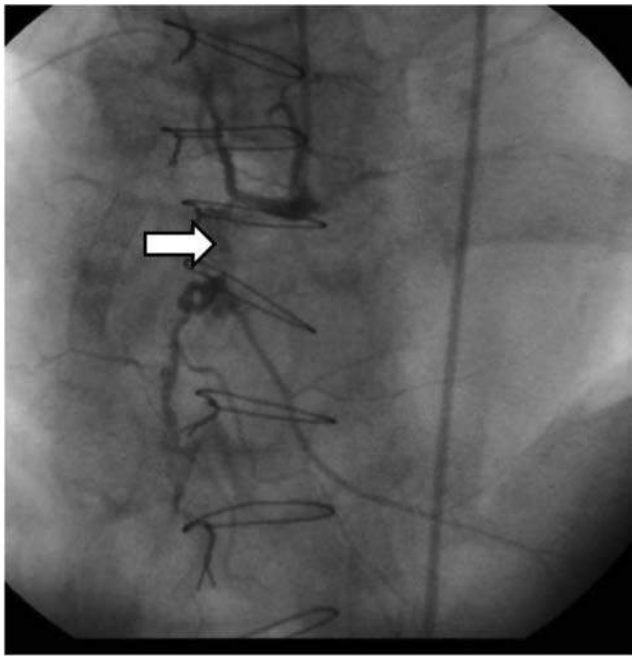

Figure 8.15b

8.17. B. Occluded RCA.
The RCA is calcified as well. The ascending aorta is normal. Note a temporary right ventricular pacer and intermittent pacing.

8.18. A. Impella, RCA stent.

8.19. A. Significant distal left main coronary artery lesion.

8.20. A. Acute anterior ST-elevation myocardial infarction (STEMI).
Note the thrombotic occlusion of the mid LAD artery.

Acute Coronary Syndromes

9

9.1. Of the following statements regarding a patient with multiple cardiac risk factors and angina-like chest pain lasting 30 min, which is the incorrect one?
- **A.** A normal echocardiogram (ECG) in the emergency room (ER) rules out myocardial infarction (MI)
- **B.** Ischemia in circumflex area is more often electrically silent
- **C.** Negative first set of cardiac markers does not rules out MI
- **D.** ECG changes could be dynamic, and it is useful to repeat every 15 min in the first hour of chest pain or when chest pain recurs

9.2. The components of thrombolysis in MI (TIMI) risk score on initial patient evaluation for suspected acute coronary syndrome (ACS) include which of the following?
- **A.** Age >65 years
- **B.** More than three coronary artery disease (CAD) risk factors
- **C.** Prior CAD with >50% lesion
- **D.** More than two anginal events in 24 h
- **E.** Use of aspirin in last 7 days
- **F.** ST deviation on ECG
- **G.** Elevated cardiac markers
- **H.** All of the above
- **I.** Some of the above

9.3. Which of the following types of chest pain rule out ACS?
- **A.** Sharp stabbing chest pain
- **B.** Pleuritic chest pain
- **C.** Chest pain reproduced by palpation
- **D.** None of the above

9.4. Guideline recommendation for ECG for patients presenting with chest pain to the ER is performance of ECG within how much time of arrival?
- **A.** 5 min
- **B.** 10 min
- **C.** 30 min
- **D.** 60 min

9.5. The GRACE risk model predicts in hospital mortality in ACS patients and includes Killip class, systolic blood pressure (BP), heart rate, age, and serum creatinine level. Which one of the following may be negatively correlated with mortality?
- **A.** Heart rate
- **B.** Systolic BP
- **C.** Killip class
- **D.** None of the above

Cardiology Board Review, First Edition. Ramdas G. Pai, Padmini Varadarajan and Sudha M. Pai.
© 2018 John Wiley & Sons, Ltd. Published 2018 by John Wiley & Sons, Ltd.

9.6. Which of the following are contraindications for NTG in patients with ACS and continuing chest pain?
- **A.** Systolic BP <90 mmHg
- **B.** Inferior MI with positive Kussmaul
- **C.** Sildenafil or vardenafil within 24 h
- **D.** Tadalafil within 48 h
- **E.** All of the above
- **F.** None of the above

9.7. Regarding use of traditional nonsteroidal anti-inflammatory drugs (NSAIDs) and cyclooxygenase-2 (COX-2) inhibitors in the setting of ACS, which of the following statements is correct?
- **A.** Traditional NSAIDs, but not COX-2 inhibitors can be used
- **B.** Traditional NSAIDs should be used, but COX-2 inhibitors can be used
- **C.** Neither traditional NSAIDs nor COX-2 inhibitors should be used
- **D.** Either can be used with no risk of harm

9.8. Which calcium channel blockers are contraindicated in ACS?
- **A.** Diltiazem
- **B.** Verapamil
- **C.** Short-acting nifedipine without a beta blocker
- **D.** None of the above

9.9. The first dose and route of aspirin use in suspected ACS is which of the following?
- **A.** 162 or 325 mg enteric coated
- **B.** 162 or 325 mg nonenteric coated chewed
- **C.** 81 mg orally
- **D.** None of the above

9.10. Aspirin in suspected ACS is avoided in which of the following patients?
- **A.** Aspirin allergy
- **B.** Recent gastrointestinal bleed
- **C.** Neither A nor B
- **D.** Both A and B

9.11. For patients with ACS, what is the recommended duration of double antiplatelet therapy (DAPT)?
- **A.** 1 month
- **B.** 6 months
- **C.** 1 year
- **D.** Forever, unless at high risk of bleeding

9.12. After NSTEMI, in addition to ASA, Plavix, beta blocker, and high-intensity statin therapy, which other agents are recommended for those with ejection fraction (EF) <40%?
- **A.** Angiotensin-converting enzyme inhibitors (ACEIs), or angiotensin receptor blockers (ARBs) in those who are ACEI intolerant
- **B.** Aldosterone blocking agent, provided creatinine is <2 mg/dL and K is <5 meq/L
- **C.** Diltiazem to prevent reinfarction
- **D.** A and B
- **E.** A and C

9.13. In a patient with non-ST elevation ACS, early coronary angiography is appropriate in which of the following situations?
- **A.** TIMI score of 5
- **B.** Continuing chest pain
- **C.** EF <40%
- **D.** Anterior wall motion abnormality
- **E.** Dynamic mitral regurgitation (MR) murmur
- **F.** All of the above

9.14. Based on current data, which of the following statements are correct in the setting of ACS?
- **A.** In the setting of ST elevation MI (STEMI), nonculprit vessels should not be stented
- **B.** In the setting of NSTEMI, it is reasonable to perform percutaneous coronary intervention (PCI) on critically stenosed nonculprit vessels as well
- **C.** Both A and B are correct
- **D.** Neither A or B are correct

9.15. Which of the following statements are correct re prasugrel use?
- **A.** It is used 10 mg once a day.
- **B.** It reduces risk of stent thrombosis compared with clopidogrel
- **C.** It has a higher risk of bleeding in those above 75 years of age or weigh <60 kg
- **D.** It is contraindicated in those with prior stroke or transient ischemic attack (TIA)
- **E.** All of the above
- **F.** None of the above

9.16. Which of the following should not be used as the sole anticoagulant during PCI?
- **A.** Fondaparinux
- **B.** Enoxaparin
- **C.** Bivalirudin
- **D.** None of the above

9.17. Which of the following statements are accurate re the duration of stoppage of antiplatelet drugs before elective coronary artery bypass grafting?
- **A.** Clopidogrel for 5 days
- **B.** Prasugrel for 7 days
- **C.** Eptifibatide and tirofiban for 2–4 h
- **D.** Abciximab for 12 h
- **E.** All of the above

9.18. Before coronary artery bypass grafting, which of the following statements is correct?
- **A.** Aspirin should be stopped a week earlier
- **B.** Aspirin should not be stopped
- **C.** Aspirin should be stopped 24 h before
- **D.** None of the above

9.19. Which of the following statements are accurate regarding triple antithrombotic therapy after MI?
- **A.** The duration should be minimized
- **B.** Concomitant proton pump inhibitors should be used

C. Triple therapy should not be used
D. A and B are correct

9.20. Which of the following agents are useful for secondary prevention post MI?
A. Vitamin E
B. Folic acid
C. Beta carotene
D. Fish oil
E. None of the above

9.21. Which of the following statements are true for older patients with non-ST elevation ACS?
A. They may have atypical symptoms
B. Benefit with medical and catheter-based therapies is similar to younger patients
C. They get less guideline-directed medical therapy
D. None of the above
E. All of the above

9.22. Compared with men, women presenting with ACS have which of the following?
A. More atypical symptoms
B. Greater chance of getting discharge from the ER
C. Higher risk of long-term complications such as heart failure (HF), shock, renal failure, stroke, readmission
D. All of the above
E. None of the above

9.23. Compared with men, women presenting with ACS have which of the following?
A. Greater incidence of normal coronary arteries
B. Higher percentage of normal EF
C. Fewer high-risk lesions
D. Same benefit with medicines
E. All of the above
F. None of the above

9.24. In ACS due to cocaine use, it is preferable to avoid which of these agents?
A. Heparin
B. Beta blocker
C. ACEI
D. None of the above

9.25. Which of the following are true re use of early glycoprotein (GP) IIb/IIIa inhibitor in the setting of acute STEMI receiving DAPT?
A. There is no clear benefit in terms of MI or death during follow-up
B. No clear evidence for a decrease in target vessel revascularization
C. There is evidence for rapidity of ST segment resolution, but not for improvement in TIMI grade 3 flow
D. All of the above

9.26. Adjunctive GP IIb/IIIa inhibitors are recommended in addition to DAPT and heparin in acute STEMI setting in which of the following situations?
A. At time of primary PCI
B. Routinely in the ER

C. Those with large thrombus burden
D. All of the above
E. At time of primary PCI or those with large thrombus burden

9.27. For a patient presenting with STEMI to a non-PCI facility, which of the following factors support immediate thrombolytic therapy?
A. Presentation within 4 h of chest pain
B. Low-risk STEMI
C. Low bleeding risk with thrombolysis
D. PCI facility is far away
E. All of the above
F. There is no indication for thrombolysis; transfer to PCI facility

9.28. A 68-year-old man presents to a non-PCI facility with anterior STEMI with ST elevation from V2 to V5. He is short of breath with bilateral rales. Chest pain started 4 h earlier. He had a TIA 6 weeks earlier and is on clopidogrel and statin. Estimated transport time to nearest catheterization laboratory is 75 min. After giving O_2, nitroglycerin (NTG), ASA, and heparin, what is the best next strategy?

A. Immediate transfer to the PCI facility
B. Give half-dose thrombolytic and then transfer
C. Patient is too high risk to transfer; give full-dose thrombolytic
D. None of the above

9.29. A 64-year-old man presents to a non-PCI facility with anterior STEMI with ST elevation from V2 to V4. He is short of breath with bilateral rales. Chest pain started 3 h earlier. He is on aspirin and statin. Estimated transport time to nearest catheterization laboratory is 4 h. There are no contraindications for thrombolytic therapy. After giving O_2, NTG, ASA chewed, and heparin, what is the best next strategy?
A. Full-dose thrombolytic and transfer to PCI facility
B. Half-dose thrombolytic and transfer to PCI facility
C. Immediately transfer to PCI facility
D. Treat medically as the patient is high risk to transfer

9.30. In patients presenting with acute MI, which of the following plasma glucose targets are desirable?
A. Tight control with glucose <110 mg/dL
B. Liberal control with glucose <300 mg/dL
C. Glucose <180 mg/dL
D. None of the above

9.31. A 65-year-old patient with diabetes mellitus and hypertension had an acute anterior MI treated within 4 h of chest pain with drug-eluting stent (DES) in left anterior descending (LAD) artery. He is stable. Serum creatinine is 1.3 mg/dL; creatine clearance 60 mL/min. His home medications include aspirin, glybenclamide, metformin, and lisinopril. What would the appropriate actions be?
A. Start on insulin infusion 1 unit per hour and titrate to blood glucose <180 mg/dL
B. Continue current medications
C. Discontinue metformin
D. Discontinue lisinopril

9.32. Which of the following statements regarding thrombus aspiration are accurate in patients with acute MI undergoing PCI?
- **A.** It is reasonable to perform in those presenting early and have large thrombus burden
- **B.** It may not be useful in those presenting late
- **C.** It is not useful in side branches subtending small myocardial territories
- **D.** All of the above
- **E.** None of the above

9.33. A 52-year-old man with no prior cardiac history presented with chest pain of 4 h and found to have acute anterior STEMI. He lost his job and medical insurance recently. He was on lisinopril and simvastatin. After administering aspirin and NTG, an immediate coronary angiography revealed a 90% lesion in the mid LAD artery with a reference diameter of 4 mm. The lesion length was 6 mm and type B. Other vessels were angiographically normal. What would the most appropriate therapy be?
- **A.** A DES
- **B.** A bare-metal stent (BMS)
- **C.** Either
- **D.** Immediate single-vessel bypass using left internal mammary artery on beating heart

9.34. In acute STEMI qualifying for reperfusion therapy, which of the following options is correct?
- **A.** Desired door to needle is ≤30 min and door to balloon time is ≤90 min
- **B.** Desired door to needle and door to balloon times are ≤90 min
- **C.** There is no indication for thrombolysis
- **D.** None of the above

9.35. Which of the following strategies may reduce time to reperfusion therapy in acute STEMI?
- **A.** Media campaign to educate patients on signs of MI
- **B.** Prehospital ECG
- **C.** Use of 9-1-1 rather than being driven to the ER by a family member
- **D.** An ER MI protocol
- **E.** All of the above

9.36. In acute STEMI, fibrinolysis is preferred over primary PCI in which of the following situations?
- **A.** Early presentation, ≤3 h
- **B.** Catheterization laboratory is not available or expert operator is not available
- **C.** Predicted (door to balloon)–(door to needle) time is greater than 60 min
- **D.** Medical contact to balloon or door to balloon time is likely to be >90 min
- **E.** All of the above

9.37. In acute STEMI, primary PCI is preferred over fibrinolysis in which of the following situations?
- **A.** Late presentation, >3 h of chest pain
- **B.** Heart failure or cardiogenic shock
- **C.** Contraindication to thrombolytics
- **D.** Diagnosis of STEMI is in doubt
- **E.** All of the above

9.38. Absolute contraindications for thrombolytics include which of the following?
- **A.** Prior intracranial hemorrhage
- **B.** Ischemic stroke within 3 months (except acute stroke <3 h)
- **C.** Closed head or facial trauma in last 3 months
- **D.** Cerebral arteriovenous malformation, berry aneurysm, or neoplasms
- **E.** All of the above
- **F.** Above are only relative contraindications and decision depends upon risk/benefit ratio

9.39. Relative contraindication for thrombolytics include which of the following?
- **A.** Systolic BP >180 mmHg or diastolic BP >110 mmHg
- **B.** Prolonged cardiopulmonary resuscitation or major surgery in <3 weeks
- **C.** Pregnancy
- **D.** Current anticoagulant use
- **E.** Noncompressible vascular punctures
- **F.** All of the above
- **G.** Some of the above

9.40. Which of the following statements about tissue plasminogen activator (tPA) are true?
- **A.** It acts more rapidly than streptokinase
- **B.** It acts better in the presence of fibrin; in its absence it is a weak plasminogen activator
- **C.** It is a surface-active agent
- **D.** Generally, dose for STEMI is 15 mg bolus + 50 mg over 30 min + 35 min over 60 min
- **E.** All of the above
- **F.** Some of the above

9.41. GUSTO-1 was a landmark trial that compared front-loaded alteplase with streptokinase in acute STEMI within 6 h. What were the findings?
- **A.** Reduced death with alteplase
- **B.** Reduced myocardial reinfarction with alteplase
- **C.** Trend to increased intracranial bleed with streptokinase
- **D.** All of the above

9.42. A 48-year-old man with acute inferior MI has a heart rate of 74 bpm, BP of 90/60 mmHg. There are no murmurs. The jugular venous pressure is 16 cmH_2O and the column seems to rise during quiet breathing. The lungs are clear. What would the appropriate treatment for low BP include?
- **A.** Intravenous bolus of normal saline
- **B.** Normal saline and dobutamine infusion if BP is still low
- **C.** Intravenous Lasix
- **D.** Infusion of norepinephrine

9.43. A 52-year-old man with reperfused (with PCI with DES) acute anterior MI got recurrent chest pain, more on breathing, associated with an increase in ST elevation leads V2 to V5 on day 3. What may this indicate?
- **A.** Stent thrombosis
- **B.** Dressler's syndrome
- **C.** Chemical pericarditis
- **D.** Potential for myocardial rupture

9.44. In what is left ventricle free wall rupture in the presence of acute MI more common?

- **A.** Elderly
- **B.** Women
- **C.** Those without prior infarcts
- **D.** Large infarcts
- **E.** Reperfusion with lytics rather than PCI
- **F.** All of the above
- **G.** Some of the above

9.45. Which of the following are true about left ventricle free wall rupture?

- **A.** It tends to occur at the junction of infarct and normal muscle
- **B.** Generally occurs after 1–4 days of infarct, but can occur as late as 3 weeks
- **C.** Usually occurs in left ventricle, but may involve right ventricle or atria
- **D.** All of the above

9.46. A 46-year-old patient with inferior STEMI, post primary PCI, became suddenly short of breath, rapidly evolving into pulmonary edema needing endotracheal intubation. On examination, his heart rate was 130 bpm, BP 80/50 mmHg, bilateral rales, and high jugular venous pressure. Cardiac sounds were soft, and there were no murmurs. The ECG showed sinus tachycardia with normal ST segments. What is the most likely diagnosis?

- **A.** Coronary stent thrombosis
- **B.** Acute pulmonary embolism
- **C.** Papillary muscle rupture
- **D.** Large RV infarct

9.47. Which of the following statements are true regarding papillary muscle rupture?

- **A.** It can occur with small subendocardial infarcts affecting tip of papillary muscle
- **B.** More commonly involves posteromedial papillary muscle
- **C.** Anterolateral papillary muscle may derive dual blood supply from LAD and circumflex arteries and is less prone to rupture
- **D.** All of the above

9.48. In the setting of acute MI, prophylactic lidocaine is recommended in which of the following situations?

- **A.** Large anterior MI
- **B.** Routinely in prehospital phase
- **C.** Routinely on arrival to the ER
- **D.** None of the above
- **E.** All of the above

9.49. Patients with acute inferior MI may get which of the following types of atrioventricular (AV) conduction problems?

- **A.** Generally, first degree or Mobitz type I, but sometimes worse
- **B.** Generally intranodal problem due to ischemia or increased vagal tone
- **C.** May respond to atropine
- **D.** Rarely needs permanent pacemaker
- **E.** All of the above

9.50. Patients with acute MI, may get which of the following types of AV conduction problems?

- **A.** Generally, Mobitz type II or complete heart block
- **B.** Generally due to extensive myocardial ischemia
- **C.** In Mobitz type II AV block, atropine can make it worse by dropping the ventricular rate by increasing atrial rate
- **D.** Generally needs permanent pacemaker
- **E.** All of the above

9.51. A 62-year-old patient presents 3 weeks after an acute MI with fever and pleuritic chest pain. There was no cough, and chest X-ray showed blunting of costophrenic angles. ECG showed inferior Q waves with no ST elevation. The white cell count was 20 000 with neutrophilia; erythrocyte sedimentation rate was 100 mm at the end of first hour. What would the best treatment be?

A. Azithromycin
B. Aspirin 650 mg q 6 h
C. NSAIDs
D. Prednisone 40 mg/day
E. None of the above

9.52. In a patient with acute anterior MI, post primary PCI, and an EF of 30%, which of the following may reduce the risk of death in the ensuing 3 months?

A. Beta blocker
B. Amiodarone
C. *d*-Sotalol
D. Flecainide

9.53. Which of the following statements about depression post MI are true?

A. It is common
B. It is associated with an increase in mortality
C. It is associated with poor medication compliance
D. Selective serotonin reuptake inhibitors improve survival
E. All of the above
F. B and D only are correct.

9.54. Which of the following statements are true about DAPT after an acute MI?

A. DAPT reduces mortality only during the first year
B. DAPT may reduce mortality beyond 1 year post MI
C. DAPT reduces mortality beyond 1 year in only those with DES
D. None of the above.

9.55. The results of the DAPT trial support the use of DAPT post MI even after 12 months. Which of the following were additional observations with use of DAPT?

A. The rate of stent thrombosis was reduced beyond 12 months
B. Risk of MI in nonstented areas was reduced
C. There was a higher risk of bleeding
D. All of the above

9.56. The PLATO trial (comparing clopidogrel with ticagrelor after ACS) showed which of the following?

A. Ticagrelor was associated with reduced major adverse cardiac and cerebrovascular events (MACCEs) after ACS compared with clopidogrel
B. Risk of major bleeding was similar for both agents overall
C. Risk of intracranial bleeding was higher with ticagrelor
D. Risk of MI was lower with ticagrelor, but stroke risk was similar
E. All of the above

9.57. The TOTAL trial randomized patients undergoing primary PCI for STEMI to thrombectomy versus no thrombectomy. What were the findings?

A. Thrombectomy did not reduce the primary endpoint of death, MI, stroke, and class IV HF
B. Stroke risk was increased in thrombectomy patients
C. No benefit of thrombectomy in the subset with high thrombus burden

D. Bailout thrombectomy needed in 8% of nonthrombectomy group
E. All of the above.

9.58. The MATRIX-ACCESS trial shows which of the following?
A. The rate of major adverse cardiac events was similar between radial and femoral access approaches
B. Net adverse cardiac events were lower in radial approach strategy
C. Risk of bleeding was lower with a adial approach
D. Major bleeding was associated with higher mortality
E. All of the above are accurate

9.59. The DANAMI 3 trial tested the hypothesis that performing PCI on non-infarct-related artery (IRA) during primary PCI for STEMI may improve outcome. Which of the following were the results?
A. The primary endpoint (death, MI, subsequent revascularization) was reduced by about 50% by performing PCI on non-IRA
B. Only MI was reduced by performing PCI on non-IRA
C. Only angina and repeat revascularization was reduced by performing PCI on non-IRA
D. There was no difference in outcome by performing PCI on non-IRA

9.60. Based on the After Eighty trial, primary PCI for STEMI in the elderly,
A. Increased stroke risk
B. Reduced MACCEs
C. Did not affect outcomes
D. None of the above

Answers

9.1. A. A normal echocardiogram (ECG) in the emergency room (ER) rules out myocardial infarction (MI).

This statement is wrong, as about 10% of acute non-ST-elevation MI (NSTEMI) may have normal ECG. ECG changes could be dynamic, where even ST elevation can come and go.

9.2. H. All of the above.

Each has a score of 1 and the maximum total score is 7. The higher the score, the higher is the 14-day event rate, progressively increasing from 4.7% to 40.9%. Note that ACS despite acetylsalicylic acid (ASA), ST deviation and positive cardiac markers portend high risk (Antman *et al.*, 2000).

9.3. D. None of the above.

In a multicenter chest pain study, ACS was present in 22%, 13%, and 7% respectively for choices A, B, and C.

9.4. B. 10 min.

9.5. B. Systolic BP.

The higher the systolic BP, the lower the risk. For others, higher numbers correlate with higher mortality (Granger *et al.*, 2003).

9.6. E. All of the above.

This is because of risk of serious hypotension. Clinical scenario in B is indicative of right ventricular (RV) infarct.

9.7. C. Neither traditional NSAIDs nor COX-2 inhibitors should be used.
This is because of potential risk of platelet aggregation. Also, these may be associated with higher risk of gastrointestinal bleeding.

9.8. C. Short-acting nifedipine without a beta blocker.
This is because of risk of reflex tachycardia.

9.9. B. 162 or 325 mg nonenteric coated chewed.

9.10. D. Both A and B.

9.11. C. 1 year.

9.12. D. A and B.
That is, ACEIs or ARBs in those who are ACEI intolerant, and aldosterone blocking agent provided creatinine is <2 mg/dL and K is <5 meq/L. Diltiazem reduced reinfarction rate in NSTEMI in the diltiazem reinfarction trial when EF was >40%. Also, in this trial, a beta blocker was not used and this was before the days of statin therapy.

9.13. F. All of the above.
These are all high risk markers.

9.14. C. Both A and B are correct.

9.15. E. All of the above.

9.16. A. Fondaparinux.
This is because of risk of catheter thrombosis.

9.17. E. All of the above.

9.18. B. Aspirin should be not be stopped.
Should continue 81–324 mg/day.

9.19. D. A and B are correct.

9.20. E. None of the above.

9.21. E. All of the above.

9.22. D. All of the above.

9.23. E. All of the above.

9.24. B. Beta blocker.
This is because of possible risk of unopposed alpha action of cocaine on coronary artery worsening spasm. The same principle holds for amphetamine-induced ACS as well.

9.25. D. All of the above.
See discussions on BRAVE-3, ON-TIME 2 and Horizons-AMI trials in Box 9.1.

9.26. E. At time of primary PCI or those with large thrombus burden.

9.27. E. All of the above.
The low-risk patients presenting early are suitable candidates. These patients may even be treated medically and noninvasively risk stratified unless there are high-risk features during hospital stay.

9.28. A. Immediate transfer to the PCI facility.
This is a high-risk patient and rapid PCI is in order. Also, history of TIA poses a contraindication for thrombolytic therapy.

9.29. A. Full-dose thrombolytic and transfer to PCI facility.

This is a high-risk patient with anterior MI, pulmonary edema, and ACS despite aspirin. In view of considerable delay in transfer to PCI facility and presentation within 4 h of chest pain, administering thrombolytic with immediate arrangement to transfer to PCI facility is appropriate as there are no contraindications for thrombolytics. See discussion on TRANSFER-AMI trial in Box 9.1. Early presentation, delay in transfer, and lack of contraindications for thrombolytics support thrombolytic therapy followed by PCI as soon as possible.

9.30. C. Glucose <180 mg/dL.

The 2009 guidelines recommend this conventional target rather than a tight control of normal glucose recommended in the 2004 guidelines. There are no trials comparing these two strategies in acute MI, but a large randomized trial in intensive care unit patients (NICE-SUGAR) indicated higher mortality in the intensive glucose control arm.

9.31. C. Discontinue metformin.

Discontinue metformin in view of radiocontrast agent administration to reduce risk of lactic acidosis. Insulin infusion is no longer recommended for tight glycemic control in acute MI any more as per 2009 guidelines.

9.32. D. All of the above.

The choices are self-explanatory. Benefit is seen in those who present early, have a large thrombus burden, and large territory is jeopardized. The EXPIRA trial, which randomized 175 patients, showed greater myocardial blush, greater 90-min ST segment resolution, and smaller infarct size at 3 months in those undergoing thrombus aspiration.

9.33. B. A bare-metal stent (BMS).

This is in view of the fact that he may not be able to reliably take clopidogrel for 1 year (uninsured) and the fact that stent size is 4 mm and short with low-risk of restenosis. A DES is superior to a BMS in diabetics in those with long lesions and small vessels (<3 mm). There was no difference in outcomes between BMS and DES except rates of later ischemia-driven target vessel revascularization (HORIZONS-AMI trial).

9.34. A. Desired door to needle is ≤30 min and door to balloon time is ≤90 min.

9.35. E. All of the above.

All of these may speed up time to reperfusion.

9.36. E. All of the above.

The first trials to show the benefit of thrombolytics over placebo in STEMI included the British ISIS-2 trial and Italian GISSI trial.

9.37. E. All of the above.

This is provided a catheterization laboratory is available with expert operator and door or contact to balloon time is likely to be <90 min.

9.38. E. All of the above.

In view of high risk of bleeding into brain. In addition, suspected aortic dissection or active bleeding (menses is not) are contraindications.

9.39. F. All of the above.

9.40. E. All of the above.

In addition, there is a risk of allergy with streptokinase and should not be repeated in the next 6-12 months.

9.41. A. Reduced death with alteplase.

There was no difference in reinfarction rates. There was a trend to increased intracranial hemorrhage with alteplase.

9.42. B. Normal saline and dobutamine infusion if BP is still low.

The patient has classical RV infarct with raised jugular venous pressure, Kussmaul's sign, and clear lungs in the setting of inferior MI. Other signs may include ST elevation in right chest leads. Intravenous fluids help improve RV output, and dobutamine will recruit noninfarcted RV myocardium to increase its performance. BP may plummet with diuresis and NTG.

9.43. D. Potential for myocardial rupture.

The focal pericarditis causing recurrent ST elevation may be due to slow seepage of blood through softened myocardium and is a marker of high risk of rupture. Dressler's syndrome occurs after 2–3 weeks. An echocardiogram would be valuable, and this may show intramural hematoma, pericardial fluid, or strands, which are risk factors for threatened myocardial rupture.

9.44. F. All of the above.

All are recognized risk factors for myomalacia cordis. In addition, being on steroids or NSAIDs and hypertension may predispose to it. The rupture could be acute or blowout (which results in immediate death), subacute (causing tamponade), or chronic (causing a pseudoaneurysm).

9.45. D. All of the above.

The rupture generally does not occur in the center of infarct. Adjacent hyperkinesis near a dyskinetic segment may promote rupture.

9.46. C. Papillary muscle rupture.

In view of flash pulmonary edema and hypotension. Hypotension combined with high left atrial pressure and large regurgitant orifice may not result in an MR murmur because of low driving pressure and lack of turbulence in the MR jet. Acute stent thrombosis is unlikely in view of lack of ST elevation. Acute pulmonary embolism and RV infarct do cause pulmonary edema.

9.47. D. All of the above.

Posteromedial papillary muscle has blood supply from right coronary artery only and is more likely to rupture.

9.48. D. None of the above.

There is no benefit for prophylactic lidocaine. The Lown grading of ventricular arrhythmias as a basis for prophylactic lidocaine has not been supported by randomized trials.

9.49. E. All of the above.

9.50. E. All of the above.

9.51. B. Aspirin 650 mg q 6 h.

This is classic Dressler's syndrome, which is thought to be autoimmune, occurring in about 1% of MIs. NSAIDs and steroids are best avoided as they may impair the left ventricle healing process and may promote rupture.

9.52. A. Beta blocker.
See details on CAST, SWORD, CAMIAT, and EMIAT in Box 9.1.

9.53. E. All of the above.

9.54. B. DAPT may reduce mortality beyond 1 year post MI.
Please see results of DAPT and TIMI-54 trials in Box 9.1.

9.55. D. All of the above.
See DAPT trial details in Box 9.1.

9.56. E. All of the above.
See details of PLATO trial in Box 9.1.

9.57. E. All of the above.
See Box 9.1.

9.58. E. All of the above are accurate.
Please see Box 9.1.

9.59. A. The primary endpoint (death, MI, subsequent revascularization) was reduced by about 50% by performing PCI on non-IRA.
See Box 9.1.

9.60. B. Reduced MACCEs.
See Box 9.1.

Chronic Coronary Artery Disease

10

10.1. The resting electrocardiogram (ECG) is normal in what percentage of patients with stable coronary artery disease (CAD)?
- **A.** About 10%
- **B.** About 50%
- **C.** About 75%
- **D.** 100%

10.2. The occurrence of conduction disturbances such as left bundle branch block (LBBB) and left anterior fascicular block (LAFB) are associated with which of the following?
- **A.** Good prognosis
- **B.** Poor prognosis
- **C.** Does not dictate prognosis
- **D.** None of the above

10.3. The presence of LV hypertrophy on the resting ECG in a patient with stable CAD may be suggestive of which of the following?
- **A.** Underlying hypertension
- **B.** Aortic stenosis
- **C.** Hypertrophic cardiomyopathy
- **D.** All of the above
- **E.** None of the above

10.4. In what percentage of patients does the resting ECG become abnormal in patients with stable CAD during an episode of angina?
- **A.** 100%
- **B.** 50%
- **C.** 75%
- **D.** 25%

10.5. What is the most common finding on the ECG in stable CAD patients during an episode of angina?
- **A.** ST segment depression
- **B.** ST segment elevation
- **C.** Normalization of previous ST abnormalities (pseudonormalization)
- **D.** None of the above

10.6. In a patient with chest pain and moderate probability of CAD and a normal resting ECG, what is the best test to order to evaluate for ischemia?
- **A.** Exercise stress ECG
- **B.** Exercise echo
- **C.** Dobutamine stress echo
- **D.** Stress nuclear

Cardiology Board Review, First Edition. Ramdas G. Pai, Padmini Varadarajan and Sudha M. Pai.
© 2018 John Wiley & Sons, Ltd. Published 2018 by John Wiley & Sons, Ltd.

10.7. What is true of a negative stress ECG for a patient receiving anti-anginal medications when evaluating for ischemia?
- **A.** Reduces the sensitivity as a screening tool
- **B.** Does not have any effect on the test
- **C.** Increases the sensitivity as a screening tool
- **D.** None of the above

10.8. A stress nuclear test is helpful in which of the following situations?
- **A.** Abnormal resting ECG changes
- **B.** LBBB
- **C.** LV hypertrophy
- **D.** All of the above

10.9. A pharmacological stress test can be ordered to evaluate for CAD in which of the following situations?
- **A.** Patients unable to exercise and achieve an adequate workload
- **B.** Peripheral vascular disease
- **C.** Patients with pulmonary disease
- **D.** All of the above

10.10. Exercise testing in asymptomatic patients without known CAD may be appropriate in which situation?
- **A.** Patients with diabetes mellitus
- **B.** Severe coronary calcifications on electron beam computed tomography (CT)
- **C.** Evidence of ischemia on ambulatory ECG
- **D.** All of the above
- **E.** None of the above

10.11. Which of the following is a true statement?
- **A.** Stress test in females is associated with higher false-positive results compared with males
- **B.** Stress test in females is associated with low rate of false-positive results compared with males
- **C.** Stress test in females is associated with higher rates of false-negative results compared with males
- **D.** Stress test in females is associated with low rates of false-negative results compared with males
- **E.** The results are similar in both men and women when stratified appropriately

10.12. In a patient with angina, with an intermediate to high pretest probability, with LBBB on ECG and with moderate ability for physical exercise, what is a reasonable diagnostic test to perform?
- **A.** Exercise stress ECG
- **B.** Exercise stress echo
- **C.** Coronary angiogram
- **D.** Adenosine stress cardiovascular magnetic resonance (CMR)

10.13. In a patient with angina, with intermediate pretest probability and able to perform moderate ability to function physically, what would be a reasonable test to perform?
- **A.** Coronary angiography
- **B.** Exercise stress ECG
- **C.** Exercise stress echo
- **D.** Coronary CT angiography (CCTA)

10.14. In a patient with an intermediate to high pretest probability for CAD and who is incapable of at least moderate exertion, what are the recommended tests for the diagnosis of CAD?

A. Dobutamine stress echo
B. Adenosine stress single-photon emission CT (SPECT)
C. Dobutamine stress SPECT
D. None of the above
E. All of the above

10.15. A 40-year-old woman is referred for evaluation of angina. Her physical exam is normal. Based on her history she is at low pretest likelihood. She has severe knee pain and is unable to perform moderate physical activity. What is the best recommended diagnostic test to evaluate her angina?

A. Coronary angiogram
B. Adenosine stress CMR
C. CCTA
D. Dobutamine stress echo
E. B, C, and D

10.16. A 55-year-old male with a history of hypertension, diabetes, smoking, and family history of CAD is referred to you for evaluation of chest pain. He is unable to walk on the treadmill due to back pain. What is a reasonable diagnostic test to perform?

A. Coronary angiogram
B. Dipyridamole stress echo
C. Stress CMR
D. CCTA

10.17. A 65-year-old male is referred for evaluation of exercise-induced angina. He has a history of hypertension, diabetes mellitus, and hypercholesterolemia. He used to smoke one pack of cigarettes a day for 20 years and has quit recently. His father was diagnosed with CAD and underwent coronary artery bypass grafting (CABG) at age 68. He is on aspirin, amlodipine 10 mg daily, lisinopril 20 mg daily and Lipitor 40 mg qd. On exam his heart rate is 60 bpm, BP 120/75 mmHg, and is otherwise unremarkable. He used to walk 2 miles a day. He now has intractable angina and is not able to perform low-intensity exercise. His primary care physician had started him on long-acting nitrates without relief. What is the best test to evaluate this patient's symptoms?

A. Exercise stress ECG
B. Exercise stress SPECT
C. Coronary angiogram
D. Dobutamine stress echo

10.18. A 63-year-old male with a history of hypertension, diabetes mellitus, hypercholesterolemia, and past history of smoking has complaints of angina. His primary care physician has optimized him on guideline-directed medical therapy and has referred him to you for further evaluation. An echocardiogram is ordered and resting LV ejection fraction (EF) is 30%. What is the best test to evaluate this patient?

A. Exercise SPECT
B. Adenosine SPECT

C. Coronary angiogram
D. Exercise treadmill

10.19. A 60-year-old female with cardiac risk factors is being evaluated for IHD. She has complaints of new-onset angina. She is on optimal medical therapy for hypertension, hypercholesterolemia and diabetes mellitus. She is unable to walk due to orthopedic limitations. She then has a dobutamine stress echocardiogram, wherein she achieves 70% of her age-predicted maximum heart rate at peak stress. What is the best approach in further evaluation of this patient?
A. Adenosine stress SPECT
B. Coronary angiogram
C. No further testing
D. Intensify medical therapy

10.20. A 69-year-old male has a history of hypertension, diabetes mellitus controlled on long-acting insulin therapy, hypercholesterolemia, and past history of smoking. He is on optimal medical therapy. He has new onset of exercise-induced angina of 1 month duration. His primary care physician ordered a stress test. His stress test was interpreted as negative. He is now referred to you for further evaluation. What is the best test to order?

A. No further testing
B. Stress nuclear imaging
C. Coronary angiogram
D. Adenosine stress CMR

10.21. A 59-year-old male patient with multiple cardiac risk factors and intractable angina was referred for a coronary angiogram. His coronary angiogram revealed a 60% stenosis in the mid LAD artery. What is the best approach in the treatment of this patient?
A. Percutaneous coronary intervention (PCI) of the 60% stenosis with a bare-metal stent
B. Fractional flow reserve (FFR)-guided PCI of the 60% stenosis
C. No further evaluation
D. PCI with a drug-eluting stent (DES)

10.22. A 71-year-old male underwent coronary angiogram to evaluate suspected IHD. His angiogram revealed 30% lesion in his mid right coronary artery (RCA), 40% lesion in left circumflex artery, and a 60% stenosis of his proximal LAD artery. FFR of the LAD artery lesion was 0.85. What is the best approach in managing this patient?
A. PCI with a DES to his proximal LAD stenosis
B. Intensify medical therapy
C. PCI of left circumflex and LAD stenosis
D. No further therapy

10.23. What is the US annual mortality rate in a middle-aged man with CAD?
A. 1.7–3%
B. 5–10%
C. 10–15%
D. None of the above

10.24. What is the US occurrence of major ischemic events in a middle-aged person with CAD?

A. 5–10%
B. 1.4–2.4%
C. 15–25%
D. None of the above

10.25. What is the 5-year survival in a patient with triple-vessel disease with an LV EF of 30% and on medical therapy?

A. 70%
B. 60%
C. 40%
D. 25%

10.26. There is an increased gradient of risk based on angiographic extent of disease. Which of the following options best describes this statement?

A. True
B. False
C. Not enough information is provided
D. None of the above

10.27. In a patient with symptomatic CAD, with three-vessel CAD on coronary angiography and an EF of 40%, what would the best approach be?

A. Multivessel PCI with DES
B. Multivessel PCI with bare metal stents
C. Coronary artery bypass grafting (CABG) including left internal mammary artery (LIMA) to LAD artery
D. Medical therapy only

10.28. According to the SYNTAX trial, what was a low SYNTAX score?

A. 23–32
B. ≤22
C. ≥33
D. 50

10.29. In the SYNTAX trial, the combined end point of death, myocardial infarction (MI), and stroke for CABG was described as what compared with DES at 5-year follow-up?

A. Equal
B. Lower
C. Higher
D. None of the above

10.30. In the SYNTAX trial, MI and repeat revascularization were described as what in the DES group compared with the CABG group?

A. Lower
B. Higher
C. Equal
D. None of the above

10.31. In the SYNTAX trial at 5-year follow-up, the occurrence of major adverse cardiac and cerebrovascular events (MACCEs) was described as what in the PCI group compared with the CABG group?

A. Equal
B. Lower
C. Higher
D. Do not know

10.32. What is the best approach for revascularization in a patient with 70% distal left main coronary disease?

A. PCI with DES
B. CABG
C. Medical therapy
D. Medical therapy plus CABG

10.33. A 65-year-old male patient has complaints of severe angina. His coronary angiogram reveals a 50% mid RCA stenosis, FFR of 0.85, and a 30% left circumflex lesion. What is the best approach in treating this patient?

A. DES to RCA stenosis only
B. DES to RCA and left circumflex arteries
C. CABG
D. Guideline-directed medical therapy

10.34. In the COURAGE trial, is it true or false that PCI with optimal medical therapy reduced the risk of death or MI compared with optimal medical therapy alone?

A. True
B. False

10.35. A 69-year-old male with hypertension and diabetes mellitus had a coronary angiogram for symptoms of angina. His resting echocardiogram showed an EF of 35%. He underwent PCI with a DES to the mid LAD artery. He is on aspirin, clopidogrel, metoprolol, and high-intensity atorvastatin. Prior to discharge, what other medication is indicated?

A. Hydrochlorothiazide
B. Angiotensin-converting inhibitor
C. Diltiazem
D. Angiotensin receptor blocker

10.36. In the patient mentioned in Question 10.35, what is the optimal duration of dual antiplatelet therapy?

A. 3 months
B. 6 months
C. 12 months
D. 6–12 months

10.37. A 54-year-old male with CAD has complained of angina which occurs two or three times per week. He is on aspirin, long-acting metoprolol, and atorvastatin. What is the next best step to add?

A. Nifedipine
B. Switch metoprolol to atenolol
C. Ranolazine
D. Long-acting nitrates

10.38. The patient in Question 10.37 is started on a long-acting nitrate. He comes back to your office for a follow-up. He indicates that his angina is not completely resolved. He also says that his BP at home is elevated 150/95 mmHg. What is the best course of action to take next?

A. Add nicardipine
B. Start ranolazine
C. No need to add anything at this time
D. Switch metoprolol to atenolol

10.39. By how much does ranolazine increase the plasma concentration of simvastatin?
- **A.** Threefold
- **B.** Twofold
- **C.** Fourfold
- **D.** Does not change the plasma concentration

10.40. How is the absorption rate of ranolazine affected by verapamil?
- **A.** Increased
- **B.** Decreased
- **C.** No change

10.41. How is the plasma concentration of ranolazine affected by ketoconazole?
- **A.** Decreased
- **B.** Increased
- **C.** It is not affected

10.42. Cocaine causes MI due to its effect on what?
- **A.** Alpha adrenergic stimulation
- **B.** Beta adrenergic stimulation
- **C.** Alpha and beta adrenergic stimulation
- **D.** Dopaminergic receptors

10.43. A 65-year-old man was admitted to the emergency room with acute anterior ST elevation MI. He underwent uneventful stenting of the proximal LAD artery within 4 h of chest pain onset. He had mild congestive heart failure, and EF on echo was 30%. In addition to beta blocker, angiotensin-converting-enzyme inhibitor, high-dose statin, aspirin, and clopidogrel, what else is likely to improve his outcome, if done before discharge?
- **A.** Implantation of an implantable cardioverter-defibrillator
- **B.** Eplerenone 25 mg daily
- **C.** Amiodarone 200 mg daily to reduce risk for VT/Vfib
- **D.** Warfarin to get an INR to 2-3 to prevent LV thrombus

10.44. A 38-year-old athletic, very muscular individual is evaluated for numbness in the left arm during exercise and weightlifting. No other medical problems. Examination is normal, as is the resting ECG. He is 68 inches tall, weighs 180 lbs, and has a short muscular neck. On stress test using a ramp protocol, he attained 95% of age-predicted heart rate at 16 METs, there was no chest pain, but had 1 mm of upsloping ST depression in inferior leads resolving within 20 s. What will you recommend?
- **A.** Coronary angiogram
- **B.** Stress nuclear test or stress echo.
- **C.** Adson's test
- **D.** Magnetic resonance imaging of C spine.

Answers

10.1. B. About 50%.

The resting ECG can be normal in about 50% of patients with stable CAD. Nonspecific ST–T changes are most commonly found on the resting ECG in stable CAD patients.

10.2. B. Poor prognosis.

The presence or development of conduction disturbances in stable CAD patients is associated with a poor prognosis. This may be suggestive of reduced left ventricular (LV) function and or multivessel disease (Fihn *et al.*, 2014).

10.3. D. All of the above.

When LV hypertrophy is evident on the resting ECG, further evaluation is needed. Such patients should undergo an echocardiogram to evaluate LV function, wall motion, wall thickness and valve function.

10.4. B. 50%.

The resting ECG becomes abnormal in 50% of patients during an episode of angina in patients with stable CAD.

10.5. A. ST segment depression.

The most common finding on a resting ECG during an episode of angina is ST depression. The most common finding is ST segment depression.

10.6. A. Exercise stress ECG.

Exercise stress ECG is probably the best test to order in this situation. The stress ECG will be very useful to evaluate for ischemia especially when the resting ECG is normal and the patient is able to exercise and achieve a good workload (Fihn *et al.*, 2014).

10.7. A. Reduces the sensitivity as a screening tool.

In the presence of anti-anginal therapy, the sensitivity of stress ECG is reduced and a negative stress test cannot be used to rule out significant CAD. Long-acting nitrates and beta blockers need to be stopped 2–3 days prior to the test.

10.8. D. All of the above.

A stress nuclear test will be helpful in the evaluation of ischemia in the presence of resting ECG changes, LBBB, LV hypertrophy, and in those receiving digoxin. In these patients, ST segments cannot be interpreted accurately during stress. An exercise stress nuclear test is relatively expensive (about three times) compared with a regular stress ECG test. Hence, a stress nuclear test should not be used as a screening tool especially in a patient with low probability of CAD. In patients with chest pain and a normal resting ECG, an exercise stress ECG should be used to screen for CAD. In patients with LBBB, pharmacological stress is preferable as exercise stress may result in false-positive septal perfusion defects.

10.9. D. All of the above.

A pharmacological stress nuclear test can be used to evaluate for ischemia in all of the situations A–C. Though pharmacological stress testing provides diagnostic accuracy comparable to an exercise stress nuclear test, exercise testing should be preferred as the exercise portion of the test provides additional information, such as heart rate and blood pressure (BP) response, amount of exercise and workload achieved, symptoms, and stress ECG abnormalities. Hence, whenever a patient can exercise and has a normal resting ECG, an exercise stress test is preferable (Fihn *et al.*, 2014).

10.10. D. All of the above.

10.11. A. Stress test in females is associated with higher false-positive results compared with males.

Exercise stress ECG was associated with a higher rate of false-positive rates based on earlier studies. But when men and women are appropriately categorized based on their pretest probability, the results of stress test are similar in both men and women, though the specificity may be slightly lower (Fihn *et al.*, 2014).

10.12. D. Adenosine stress cardiovascular magnetic resonance (CMR).

In a person with angina and with moderate physical limitation, a pharmacological stress is recommended. According to the 2012 ACC/AHA guidelines (Fihn *et al.*, 2012), pharmacological stress CMR is useful in the diagnosis of CAD (class IIa) recommendation (Nandalur *et al.*, 2007; Hamon *et al.*, 2010; Schuetz *et al.*, 2010).

10.13. D. Coronary CT angiography (CCTA).

In a person with an intermediate pretest probability of CAD, with ability to exercise moderately a CCTA can be useful to diagnose CAD (class IIb) recommendation according to the 2012 ACC/AHA guidelines (Fihn *et al.*, 2012; Budoff *et al.*, 2008; Schuetz *et al.*, 2010).

10.14. E. All of the above.

In a patient with intermediate to high pretest likelihood of CAD and unable to perform at least moderate exertion, then pharmacological stress with either echo or nuclear imaging is recommended (class 1) according to the 2012 ACC/AHA guidelines (Fihn *et al.*, 2012).

10.15. E. B, C, and D.

In a patient with low pretest likelihood and unable to exercise, pharmacological stress or CCTA are a reasonable diagnostic test (class IIa, level of evidence C) (Fihn *et al.*, 2012).

10.16. C. Stress CMR.

In a patient with intermediate to high pretest likelihood and unable to exercise, stress CMR is reasonable to perform for evaluation of angina (class IIa, level of evidence B). CCTA is reasonable to perform in a patient with low to intermediate likelihood of ischemic heart disease (IHD), who is incapable of at least moderate physical activity (class IIa, level of evidence B) (Fihn *et al.*, 2012).

10.17. C. Coronary angiogram.

This patient has a high pretest likelihood of IHD and has intractable symptoms. Coronary angiogram is the best test to evaluate for CAD (class I, level of evidence C) as he is on optimal guideline-directed medical therapy and may be amenable for coronary revascularization (2014 ACC/AHA guideline update) (Fihn *et al.*, 2014).

10.18. C. Coronary angiogram.

This patient has high probability of multivessel disease based on risk factors, angina, and low EF. His LV EF is 30%, which poses a high risk in the presence of IHD. Patients with high likelihood of IHD based on noninvasive testing will benefit from a coronary angiogram provided they are amenable to revascularization (class IIa, level of evidence C).

Features of high risk (>3% annual mortality rate) include: resting LV EF <35%, high-risk treadmill score ≤11, severe exercise-induced LV dysfunction (<35%), stress-induced perfusion defect, especially anterior wall, multiple perfusion defects of moderate size on stress-induced imaging, large fixed perfusion defect on thallium-201 imaging along with LV dilatation or increased lung uptake, moderate perfusion defect on thallium-201 imaging associated with LV dilatation or increased lung uptake, wall motion abnormality developing in two segments at low dose of dobutamine (<10 μg/(kg min)) or at a low heart rate <120 bpm, or extensive ischemia on a stress echocardiogram.

10.19. B. Intensify medical therapy.

This patient has risk factors for IHD. Her primary care physician ordered a dobutamine stress echo. The results of the noninvasive test are indeterminate as she did not achieve target heart rate. Owing to her symptoms, she should undergo coronary angiogram for further evaluation. According to the 2014 ACC/AHA guidelines (Fihn *et al.*, 2014), coronary angiography is reasonable in patients with suspected symptomatic IHD who cannot undergo diagnostic stress testing, or have indeterminate or nondiagnostic stress tests, when there is a high likelihood that the findings will result in important changes to therapy (class IIa, level of evidence C).

10.20. C. Coronary angiogram.

This patient probably has a false-negative stress test. Based on his risk factors and symptoms his pre- and post-test likelihood of IHD are high. Despite a negative stress test, coronary angiogram is warranted here as the findings on coronary angiogram may result in important changes to therapy. The 2014 update of ACC/AHA guidelines (Fihn *et al.*, 2014) state that "Coronary angiography might be considered in patients with stress test results of acceptable quality that do not suggest the presence of CAD when clinical suspicion of CAD remains high and there is a high likelihood that the findings will result in important changes to therapy" (class IIb, level of evidence C).

There are high-quality clinical data to base recommendations for performing coronary angiography in suspected IHD patients. All prior trials in this subset of patients have required angiography. Additionally, the incremental benefits of detecting CAD by coronary angiography need to be determined. The ISCHEMIA (International Study of Comparative Health Effectiveness with Medical and Invasive Approaches) trial is an ongoing trial randomizing patients with at least moderate ischemia on stress testing to a strategy of optimal medical treatment alone versus routine coronary angiogram along with medical therapy. Prior to randomization, patients with normal renal function will undergo CCTA to exclude left main or severe CAD.

10.21. B. Fractional flow reserve (FFR)-guided PCI of the 60% stenosis.

This patient with a 60% stenosis of his mid LAD artery should undergo FFR. If the FFR is <0.80 then that lesion should be intervened on. The FAME-2 trial (see Box 10.1) showed that, in patients with stable CAD and functionally significant stenosis, FFR-guided PCI along with best medical therapy compared with best medical therapy alone decreased the need for urgent revascularization (De Bruyne *et al.*, 2012).

10.22. B. Intensify medical therapy.

This patient has a coronary stenosis that was shown to be not significant for ischemia based on FFR. In the FAME-2 trial, it was shown that the outcomes were favorable with best medical therapy when there was no demonstrable ischemia by FFR. Hence, medical therapy should be intensified in this patient. Please refer to discussion in Question 10.21.

10.23. A. 1.7–3%.

10.24. B. 1.4–2.4%.

Data from the Framingham study before the widespread use of aspirin, beta blockers have shown the annual mortality rate in patients with chronic stable angina was 4%. The use of aggressive medical therapy has improved the prognosis. In recent studies the annual mortality rate in stable patients with CAD has been shown to be 1.7–3% and the occurrence of major ischemic events was around 1.4–2.4% (The PEACE Trial Investigators, 2004).

10.25. C. 40%.

Data from the CASS study (see Box 10.1) have shown that 5-year survival in medically treated patients with severe triple-vessel disease and an LV EF ≤34% was poor at 40% (Emond *et al.*, 1994). If the LV EF was greater than 50% then the 5-year survival was around 80%. As the stenosis severity increases and LV function is reduced below 34%, prognosis is adversely affected.

10.26. A. True.

Studies have shown that there is an increased gradient of risk with increased angiographic extent of disease. It has been shown that in medically treated symptomatic CAD patients the annual mortality rate is 2% when there is a 50% stenosis in only one of the major epicardial coronary vessels. In patients with an obstructive lesion proximal to the first septal perforator the 5-year survival rate is 90%, compared with 98% in patients with more distal LAD stenosis (Califf *et al.*, 1996).

10.27. C. Coronary artery bypass grafting (CABG) including left internal mammary artery (LIMA) to LAD artery.

In the 2014 ACC/AHA guidelines (Fihn *et al.*, 2014), CABG has received a class 1 recommendation in patients with diabetes mellitus and multivessel CAD (three vessel or complex two vessel including proximal LAD artery provided a LIMA graft can be anastomosed to the LAD artery). See Box 10.1 regarding the FREEDOM trial (Faroukh *et al.*, 2012), the SYNTAX trial (Kappatein *et al.*, 2013), and the meta-analysis of eight trials, including the FREEDOM trial (Verma *et al.*, 2013).

10.28. B. ≤22.

A low SYNTAX score was defined as ≤22 in the SYNTAX trial. This score was based on location, severity, and extent of stenosis, with a low score indicating less complicated anatomy. A score of 23 to 32 was defined as intermediate, and a score ≥33 was defined as a high-risk score.

10.29. B. Lower.

In the SYNTAX study (see Box 10.1) the occurrence of combined end point in the CABG group was lower compared with DES (16.7% versus 20.8%, $P = 0.03$ respectively) (Kappatein *et al.*, 2013).

10.30. B. Higher.

In the SYNTAX trial (see Box 10.1) the MI rate and repeat revascularization were higher in the DES group when compared with the CABG group: MI 3.6% in the CABG versus 7.1% in the DES group; repeat revascularization 10.7% for CABG versus 19.7% for the DES group (Kappetein *et al.*, 2011).

10.31. C. Higher.

In the SYNTAX trial (see Box 10.1), at 5-year follow-up the occurrence of MACCEs was higher in the DES group compared with the CABG group: 37.3% versus 26.9% respectively, $p < 0.0001$ (Serruys *et al.*, 2009).

10.32. D. Medical therapy plus CABG.

The best approach to revascularization in this patient is optimizing medical therapy and CABG (class 1, level of evidence B) (Fihn *et al.*, 2012).

10.33. D. Guideline-directed medical therapy.

CABG or PCI in this patient is class III (harm) according to the 2012 ACC/AHA guidelines (Fihn *et al.*, 2012). CABG or PCI should not be performed with the sole intent of improving survival in patients with stable IHD with one or more coronary stenoses that are not anatomically significant (<70% in non-left main coronary artery or FFR >0.80, no or mild ischemia on noninvasive testing, stenosis involving only the RCA or left circumflex artery, or subtend only a small area of viable myocardium.

10.34. B. False.

See Box 10.1 about the COURAGE trial results.

10.35. B. Angiotensin-converting inhibitor.

Since his LV EF is <40%, he should be started on angiotensin-converting enzyme inhibitor.

10.36. C. 12 months.

According to current ACC/AHA guidelines (Fihn *et al.*, 2014), dual antiplatelet therapy with aspirin and clopidogrel or prasugrel should be continued uninterrupted for 12 months, though the benefits and risks of treatment beyond 1 year are uncertain (Mauri *et al.*, 2014). See Box 10.1 about the DAPT study.

10.37. D. Long-acting nitrates.

This patient should be started on long-acting nitrates to help control his angina.

10.38. A. Add nicardipine.

This patient has elevated BP and his angina is persistent despite being on a long-acting nitrate and a beta blocker. The next best medication to add would be nicardipine, as he has elevated BP. The half-life of this drug is 2–4 h, but appears to have greater vascular selectivity. For chronic stable angina, it is supposed to be as effective as verapamil or diltiazem, and when combined with a beta blocker the efficacy is enhanced.

10.39. B. Twofold.

Ranalozine increases plasma concentration of simvastatin twofold.

10.40. A. Increased.

The absorption of ranolazine is increased by verapamil by inhibition of P-glycoprotein system.

10.41. B. Increased.

Ranolazine is metabolized by the cytochrome P450 system. Ketoconazole is a strong inhibitor of cytochrome P450 system. Hence, the concentration of ranolazine will be increased when co-administered with ketoconazole.

10.42. A. Alpha adrenergic stimulation.

Cocaine causes MI by its alpha adrenergic stimulation, which causes coronary vasoconstriction and increased myocardial oxygen demand. Thus, when treating such patients, pure beta blockers are contraindicated and drugs such as labetolol which block both alpha and beta adrenergic receptors should be used.

10.43. B. Eplerenone 25 mg daily.

As the EF is <35%. There is no indication for an implantable cardioverter-defibrillator unless EF after 40 days remains <35%.

10.44. C. Adson's test.

The features are consistent with thoracic outlet syndrome. The stress test is negative at very high workload and there is no indication for further ischemic work-up.

Box 10.1 Clinical Trials

- **FAME-2** (De Bruyne *et al.*, 2012). Hypothesis was that FFR-guided PCI of functionally significant stenosis along with best medical therapy would be superior to best medical therapy alone. A total of 1220 patients were enrolled, 880 were randomized and 332 enrolled in registry. Primary end point was a composite of death, MI, or urgent revascularization. The trial was halted prematurely because of a significant difference in the primary outcome between the two groups: 4.3% in the PCI group and 12.7% in the medical therapy group (hazard ratio with PCI 0.32, 95% confidence interval (CI) 0.19–0.53, $P < 0.001$). The difference was driven by a lower rate of urgent revascularization in the PCI group. In patients without ischemia the outcome appeared to be favorable with best medical therapy alone.
- **CASS trial** (Emond *et al.*, 1994). This study describes the impact of clinical, angiographic, and demographic characteristics on the long-term survival of Coronary Artery Surgery Study (CASS) patients while they were under medical treatment. All CASS patients who had not received heart surgery before enrollment (23 467 patients) were included in this survival analysis while they were under medical treatment or surveillance. Follow-up time ranged from 0 to 17 years (median: 12 years). Overall, 12-year survival for patients with zero-, one-, two-, and three-vessel disease is 88%, 74%, 59%, and 40% respectively. The 12-year survival for patients with at least one diseased vessel and EFs in the ranges 50–100%, 35–49%, and 0–34% is 73%, 54%, and 21% respectively.
- **FREEDOM trial** (Faroukh *et al.*, 2012). In this trial, 1900 patients were randomized to either PCI or CABG. The primary outcome in this trial was a composite of death, nonfatal MI, or nonfatal stroke. The 5-year rates were 18.7% in the CABG group versus 26.6% in the DES group ($p = 0.005$). The benefit of CABG was driven by differences in rates of MI ($p < 0.001$) and death from any cause ($p = 0.049$). Stroke was more frequent in the CABG group, and 5-year survival rates were 5.2% in the CABG group compared with 2.4% in the DES group ($p = 0.03$).

- **SYNTAX trial.**
  - The 5-year update from the SYNTAX trial (Kappatein *et al.*, 2013) did not show a significant survival advantage with CABG over DES in patients with diabetes mellitus (12.9% with CABG versus19.5% with DES, $p = 0.065$).
